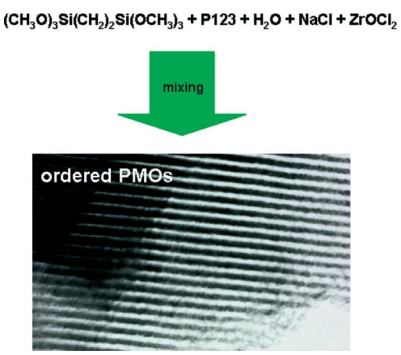
Two new magnesium 2,6-naphthalenedicarboxylate (ndc) metal–organic frameworks, $[Mg_3(ndc)_3(dif)_4]$ (**1**) (dif = *N*,*N*-diisopropylformamide) and $[Mg_3(ndc)_3(dmf)_2(CH_3OH)(H_2O)]$(dmf) (**2** = TUDMOF-3) (dmf = *N*,*N*-dimethylformamide), have been synthesised. TUDMOF-3 has a permanent porosity with a Langmuir surface area of 632 $m^2$ $g^{-1}$, a specific pore volume of 0.21 $cm^3$ $g^{-1}$ and a hydrogen storage capacity of 1.23 wt.-% (77 K, 1 bar). Compound **1** is not porous.

### Hybrid Mesostructures

**S.-R. Zhai, S. S. Park, M. Park, M. H. Ullah, C.-S. Ha* ..... 5480–5488**

Direct Synthesis of Zr-Containing Hybrid Periodic Mesoporous Organosilicas with Tunable Zirconium Content

**Keywords:** Silicates / Template synthesis / Orangic–inorganic hybrid composites / Mesoporous materials



Highly ordered Zr-containing periodic mesoporous organosilicas (ZrPMO) were successfully synthesized, for the first time, by employing a $ZrOCl_2$/NaCl combination as the promoting agent; the addition of extra amounts of acid was not needed throughout the synthetic process.

## Contrast Agents

The propylene bridge in the skeleton of the $H_5EPTPACH_2OH$ ligand optimizes the water-exchange rate of the $[Gd(EPTPA\text{-}CH_2OH)(H_2O)]^{2-}$ complex, for efficiency as a MRI contrast agent, as a result of the steric compression imposed around its water binding site, as shown by solution relaxometric characterization. The hydroxymethyl substituent group is useful for conjugation of the reporter group. However, these changes, relative to those incurred by the DTPA chelate, significantly decrease its thermodynamic and kinetic stability.

## Isomerism of Copper Complexes

The preference for axial or equatorial positioning of the bridging atoms and of the amine or pyridine N centers of tridentate ligands L in $LCu^{II}(\mu\text{-}X)_2Cu^{II}L$ complexes was probed experimentally and by DFT calculations. Their preference for either a *syn* or *anti* configuration in an equatorial/equatorial situation was also evaluated.

# ($\eta^5$-Cyclopentadienyl)($\eta^4$-tetrasila- and $\eta^4$-trisilagermacyclobutadiene)cobalt: Sandwich Complexes Featuring Heavy Cyclobutadiene Ligands

**Kazunori Takanashi,[a] Vladimir Ya. Lee,[a] Masaaki Ichinohe,[a] and Akira Sekiguchi*[a]**

**Keywords:** Cobalt / Cyclobutadiene ligand / Cyclopentadienyl ligand / Germanium / Silicon

($\eta^5$-Cyclopentadienyl)($\eta^4$-tetrasilacyclobutadiene)cobalt {[($\eta^4$-$R_4Si_4$)CoCp], **2**} and ($\eta^5$-cyclopentadienyl)($\eta^4$-trisilagermacyclobutadiene)cobalt {[($\eta^4$-$R_4Si_3Ge$)CoCp], **4**} (R = SiMe*t*Bu$_2$) were synthesized by reaction of the dipotassium salts of tetrasilacyclobutadiene dianion $K^+_2$·$[R_4Si_4]^{2-}$ (**1**) and trisilagermacyclobutadiene dianion $K^+_2$·$[R_4Si_3Ge]^{2-}$ (**3**) with $[CpCoI_2(PPh_3)]$. Alternatively, **4** was prepared by the reaction of **3** with $[Cp_2Co]^+$·$[PF_6]^-$. X-ray crystallographic analysis of **2** confirmed its sandwich-type structure, manifesting a nearly square-planar $Si_4$ ring and diagnostic perhaptocoordination of both ligands, $\eta^4$-tetrasilacyclobutadiene and $\eta^5$-cyclopentadienyl, to the Co atom.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2007)

## Introduction

Sandwich complexes, known since the revolutionary discovery of ferrocene in 1951[1a,1b] and the determination of its novel structure in 1952,[1c,1d] constitute one of the most important classes of organotransition metal complexes. Accordingly, such sandwich complexes, particularly those featuring cyclopentadienyl and cyclobutadiene ligands, attracted a great deal of interest from both the fundamental and industrial organometallic chemistry communities.[2] For example, ($\eta^5$-cyclopentadienyl)[$\eta^4$-tetrakis(trimethylsilyl)cyclobutadiene]cobalt [$\eta^4$-$(Me_3Si)_4C_4$]CoCp (**A**)[3] represents such an important sandwich complex that found an interesting synthetic application as a convenient precursor for the 6π-electron aromatic derivative of the dilithium salt of the cyclobutadiene dianion.[3c,3d] The novel field of transition metal complexes with cyclic polyene ligands incorporating the heavier Group 14 elements represents another organometallic challenge that is very attractive from the viewpoint of their unique electronic structures and possible practical applications.[4] Thus, a series of transition metal complexes with heavy cyclopentadienyl ligands has been synthesized by Tilley,[4a–4g] whereas Kira recently reported the preparation of a (silacyclobutadiene)Co complex[4m] and Tokitoh reported the synthesis of sila-, germa- and stannaarene complexes of Cr, Mo and Ru.[4h–4l] We have also contributed to the field, utilizing tetrasilacyclobutadiene[4n,4o] and heavy cyclopentadienyl[4h] as a novel ligand for transition metal complexes. Thus, we succeeded in the synthesis of two types of carbonyl(tetrasilacyclobutadiene) transition metal complexes, $K^+$·[($\eta^4$-$R_4Si_4$)$Co(CO)_2]^-$ (**B**)[4n] and [($\eta^4$-$R_4Si_4$)$Fe(CO)_3$] (**C**)[4o] (R = SiMe*t*Bu$_2$) (Scheme 1), which show a stronger π-donating ability of the tetrasilacyclobutadiene ligand compared with that of its carbon counterpart. However, to the best of our knowledge, sandwich complexes in which the ring of one of the ligands entirely consists of heavier Group 14 elements are still unknown. In this paper, we report the synthesis and structural characterization of the first sandwich cyclopentadienyl complexes, featuring $\eta^4$-tetrasilacyclobutadiene and $\eta^4$-trisilagermacyclobutadiene ligands.

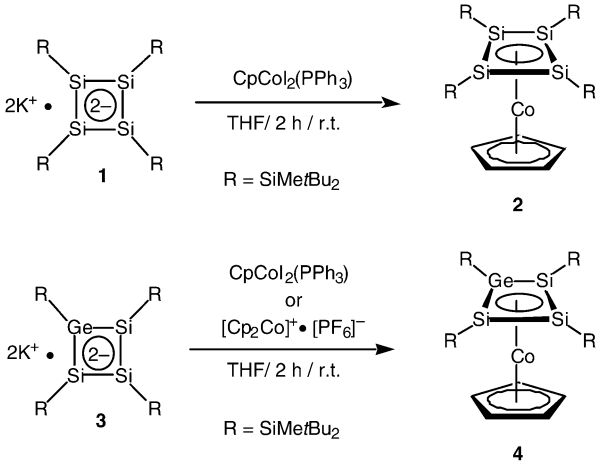
## Results and Discussion

Reaction of the dipotassium salt of tetrasilacyclobutadiene dianion derivative $K^+_2{\cdot}[R_4Si_4]^{2-}$ (R = SiMe*t*Bu$_2$) (**1**)[5] with [CpCoI$_2$(PPh$_3$)] in THF produced the corresponding sandwich complex, ($\eta^5$-cyclopentadienyl)[$\eta^4$-tetrakis(di-*tert*-butylmethylsilyl)tetrasilacyclobutadiene]cobalt {[($\eta^4$-$R_4Si_4$)CoCp], **2**}, accompanied by elimination of PPh$_3$ (Scheme 2). Complex **2** was isolated as air- and moisture-sensitive orange crystals in 36% yield by recrystallization from hexane. Both the $^1$H and $^{13}$C NMR spectra of **2** display only one set of signals for the Me and *t*Bu groups of the *t*Bu$_2$MeSi substituents because of the free rotation about the vertical axis passing through the Si$_4$ ring center and the Co atom. The cyclopentadienyl carbon signals are observed in the normal region at $\delta$ = 80.3 ppm. The endocyclic silicon atoms of the Si$_4$ ring resonate at $\delta$ = 0.4 ppm; this value being shifted upfield compared with typical values of sp$^2$-Si atoms.[6] Our GIAO computations well reproduced such chemical shift, giving a value of $\delta$ = –4.7 ppm for the model complex [($\eta^4$-R′$_4$Si$_4$)CoCp] (**2′**) (R′ = SiMe$_3$).[7] Such general tendency of the great shielding of skeletal Si atoms of the tetrasilacyclobutadiene ligand upon its complexation to transition metal atoms, previously observed by us for other transition metal complexes, could be most reasonably achieved in terms of the strong 3d(Co)→π*(Si$_4$) π back donation. Utilizing the same synthetic procedure, we also prepared the Si$_3$Ge hybrid heavy cyclobutadiene complex ($\eta^5$-cyclopentadienyl)[$\eta^4$-tetrakis(di-*tert*-butylmethylsilyl)trisilagermacyclobutadiene]cobalt {[$\eta^4$-$R_4Si_3Ge$]CoCp, **4**} (yield 41%) by reaction of the dipotassium salt of the trisilagermacyclobutadiene dianion derivative $K^+_2{\cdot}[R_4Si_3Ge]^{2-}$ (R = SiMe*t*Bu$_2$) (**3**)[8] with [CpCoI$_2$(PPh$_3$)] in THF. Alternatively, **4** was synthesized (yield 62%) by the reaction of **3** with $[Cp_2Co]^+{\cdot}[PF_6]^-$, accompanied by the elimination of CpK, similar to the case of complex **B**.[4n] Although highly air- and moisture-sensitive, **4** is thermally very stable up to 287 °C. The structure of **4** was established by NMR spectral and X-ray diffraction data. Thus, **4** exhibits three sets of signals for the Me and *t*Bu groups in both $^1$H and $^{13}$C NMR spectra, as expected. The $^{29}$Si NMR spectrum of **4** shows a total of five signals ($\delta$ = –13.7, 22.0, 24.1, 32.1 and 43.5 ppm), of which the most upfield ($\delta$ = –13.7 ppm) and the most downfield ($\delta$ = 43.5 ppm) signals were attributed to the endocyclic Si atoms with the latter signal corresponding to Si atoms bound to the Ge atom.

The X-ray crystal structure of **2** is represented in Figure 1. The bond lengths between the skeletal silicon and cobalt atoms in **2** range from 2.3862(7) to 2.3990(7) Å, which is in the range reasonably expected for a tetrahaptocoordinated tetrasilacyclobutadiene ligand, being similar to those in the previously reported complex $K^+{\cdot}[(\eta^4\text{-}R_4Si_4)Co(CO)_2]^-$ (**B**) [2.3935(7)–2.4225(7) Å].[4n] The endocyclic silicon–silicon bond lengths in **2** spread over the narrow range of 2.2718(10)–2.2725(9) Å, which is just in between the typical values of an Si–Si single (2.34 Å) and an Si=Si double (2.15 Å) bond.[9] The difference between the longest and shortest endocyclic silicon–silicon bond in **2** ($\Delta$ = 0.0007 Å) is smaller than that in ($\eta^4$-$R_4Si_4$)Fe(CO)$_3$ (**C**) ($\Delta$ = 0.0192 Å),[4o] primarily because of the different degree of steric interaction between the bulky *t*Bu$_2$MeSi substituents on the tetrasilacyclobutadiene ring and cyclopentadienyl (in **2**) or carbonyl (in **C**) ligands. The latter reason affects also the orientation of the *t*Bu$_2$MeSi groups in **2** to minimize their mutual steric interaction: they are arranged in a clockwise manner with the silyl substituents' Si atoms being nearly coplanar with the Si$_4$ ring plane [the up and down deviations of the Si atoms from the Si$_4$ mean plane are 0.0198(7) and 0.0043(7) Å, respectively]. On the other hand, the small Me groups of the *t*Bu$_2$MeSi substituents in **C**[4o] are uniformly directed toward the carbonyl ligands. Remarkably, the tetrasilacyclobutadiene ligand in **2** possesses an almost regular square-planar geometry, with the sum of the interior bond angles being 360.0°, which corresponds to a negligible folding of 1.1°. The crystal structure of **4** was also unambiguously determined by X-ray crystallography to confirm its sandwich composition; however, a precise structural determination was prevented by the positional disorder between the skeletal Si and Ge atoms.



Scheme 2. Synthesis of heavy cyclobutadiene complexes **2** and **4**.

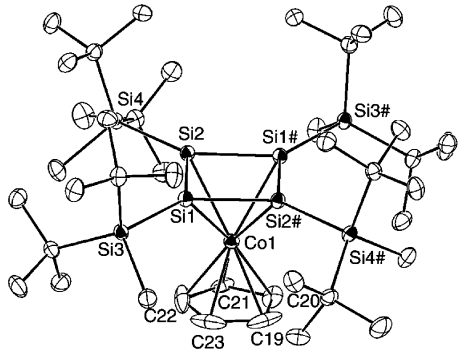


Figure 1. ORTEP drawing of **2** (30% probability level, hydrogen atoms are not shown). Selected bond lengths [Å]: Si1–Si2 2.2725(9), Si1–Si2# 2.2718(10), Si1–Co1 2.3862(7), Si2–Co1 2.3990(7), Si1–Si3 2.3784(9), Si2–Si4 2.3846(8). Selected bond angles [°]: Si2–Si1–Si2# 90.08(3), Si1–Si2–Si1# 89.92(3). Dihedral angle [°]: Si1–Si2–Si1#/Si1–Si2#–Si1# 1.10(2).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

In order to gain a deeper insight into the structures of these novel sandwich complexes, we performed computations on the $Me_3Si$-substituted model [($\eta^4$-R′$_4Si_4$)CoCp] (R′ = $SiMe_3$) (**2′**) and the complex [$\eta^4$-$(Me_3Si)_4C_4$]CoCp (**A**). The structural parameters for experimental compounds **2** and **A**[3d] and those of calculated **2′** and **A** are summarized in Table 1. The structural features of **2** were fairly well reproduced in the calculated structure **2′**, except for the location of the silyl substituents' Si atoms. Thus, whereas these Si atoms in **2** are nearly coplanar with the $Si_4$ ring, in the optimized structure of **2′** they are tilted towards the Co atom from the $Si_4$ mean plane by 0.236–0.261 Å. In contrast, the silyl substituents' Si atoms in the calculated structure of **A** are bent away from the Co atom, being situated 0.294–0.330 Å above the $C_4$ ring. Such a distinction in the position of the silyl substituents in the calculated structures of **2′** and **A** would be reasonably explained by the difference in the ring size of cyclobutadienes $R_4E_4$ (E = Si, C; R = $SiMe_3$), implying different extents of the effective π($R_4E_4$)–3d(Co) orbitals' interaction depending on the size of the carbon 2pπ- and silicon 3pπ-orbitals, as schematically illustrated in Figure 2. The experimentally observed in-plane positions of the silyl substituents in **2** are due to the balance between the two opposite tendencies: favorable orbital interactions and unfavorable steric repulsion between the bulky silyl substituents and Cp ligand.

Table 1. Geometrical parameters of the experimental (**2** and **A**) and calculated (**2′** and **A**) structures of the cyclobutadiene cobalt complexes [($\eta^4$-$R_4E_4$)CoCp] (E = Si, C).

| | **2** (E = Si) experimental | **2′** (E = Si) calculated | **A** (E = C)[a] experimental | **A** (E = C) calculated |

## Conclusions

New sandwich complexes featuring heavy cyclobutadiene ligands ($\eta^5$-cyclopentadienyl)($\eta^4$-tetrasilacyclobutadiene)-cobalt {[($\eta^4$-$R_4Si_4$)CoCp], **2**} and ($\eta^5$-cyclopentadienyl)($\eta^4$-trisilagermacyclobutadiene)cobalt {[($\eta^4$-$R_4Si_3Ge$)CoCp], **4**} (R = $SiMe$*t*$Bu_2$) were synthesized by the reaction of the corresponding dipotassium salts of the tetrasilacyclobutadiene dianion $K^+_2$·$[R_4Si_4]^{2-}$ (**1**) and the trisilagermacyclobutadiene dianion $K^+_2$·$[R_4Si_3Ge]^{2-}$ (**3**) with [$CpCoI_2(PPh_3)$]. The systematic comparison between **2** and its carbon analog, ($\eta^5$-cyclopentadienyl)[$\eta^4$-tetrakis(trimethylsilyl)cyclobutadiene]cobalt {[$\eta^4$-$(Me_3Si)_4C_4$]CoCp (**A**)}, showed significant structural differences between them caused by the difference in the ring size of the cyclobutadiene ligand $R_4E_4$ (R = $SiMe$*t*$Bu_2$, E = Si vs. R = $SiMe_3$, E = C).

## Experimental Section

**Starting Materials:** The dipotassium salt of the tetrasilacyclobutadiene dianion, $K^+_2$·$[R_4Si_4]^{2-}$ (R = $SiMe$*t*$Bu_2$) (**1**), was prepared according to a published experimental procedure.[5] The dipotassium salt of the trisilagermacyclobutadiene dianion, $K^+_2$·$[R_4Si_3Ge]^{2-}$ (R = $SiMe$*t*$Bu_2$) (**3**), was also synthesized in a similar manner.[8] The cobalt complex [$CpCoI_2(PPh_3)$] was synthesized according to a literature procedure,[10] whereas complex $[Cp_2Co]^+$·$[PF_6]^-$ was commercially available and purchased from Tokyo Kasei Co.

**($\eta^5$-Cyclopentadienyl)[$\eta^4$-tetrakis(di-*tert*-butylmethylsilyl)tetrasilacyclobutadiene]cobalt {[$\eta^4$-(*t*$Bu_2$MeSi)$_4Si_4$]CoCp} (2):** The dipotassium salt of the tetrasilacyclobutadiene dianion, $K^+_2$·$[R_4Si_4]^{2-}$ (R = $SiMe$*t*$Bu_2$) (**1**) (104 mg, 0.094 mmol), and [$CpCoI_2(PPh_3)$] (55 mg, 0.095 mmol) were placed in a reaction tube with a magnetic stirring bar. Oxygen-free dry THF (2 mL) was introduced by vacuum transfer, and the reaction mixture was stirred at room temperature to give an orange solution within 1 h. Then the solvent was removed in vacuo, and dry hexane was introduced. After inorganic salt was removed by centrifugation, the residue was recrystallized from hexane (1 mL) at –30 °C to give **2** (29 mg, 36%) as orange crystals; m.p. 290–292 °C. $^1$H NMR (400 MHz, $C_6D_6$): $\delta$ = 0.30 (s, 12 H, *t*$Bu_2$*Me*Si), 1.22 (s, 72 H, *tBu*$_2$MeSi), 5.33 (s, 5 H, $C_5H_5$) ppm. $^{13}$C NMR (100.6 MHz, $C_6D_6$): $\delta$ = –3.6, 21.5, 30.4, 80.3 ppm. $^{29}$Si NMR (79.5 MHz, $C_6D_6$): $\delta$ = 0.4 (skeletal Si), 22.2 (substituents Si) ppm. UV/Vis (THF): $\lambda$ ($\varepsilon$) = 294 (23000), 347 (6100), 407 (3200) nm. $C_{41}H_{89}CoSi_8$ (865.78): calcd. C 56.88, H 10.36; found C 57.26, H 10.30.

**($\eta^5$-Cyclopentadienyl)[$\eta^4$-tetrakis(di-*tert*-butylmethylsilyl)trisilagermacyclobutadiene]cobalt {[$\eta^4$-(*t*$Bu_2$MeSi)$_4Si_3$Ge]CoCp} (4) by Reaction of $K^+_2$·$[R_4Si_3Ge]^{2-}$ (R = $SiMe$*t*$Bu_2$) and [$CpCoI_2(PPh_3)$]:** The dipotassium salt of the trisilagermacyclobutadiene dianion, $K^+_2$·$[R_4Si_3Ge]^{2-}$ (R = $SiMe$*t*$Bu_2$) (**3**) (129 mg, 0.112 mmol), and [$CpCoI_2(PPh_3)$] (65 mg, 0.112 mmol) were placed in a reaction tube with a magnetic stirring bar. Oxygen-free dry THF (2 mL) was introduced by vacuum transfer, and the reaction mixture was stirred at room temperature to give an orange solution within 1 h. Then the solvent was removed in vacuo, and dry hexane was introduced. After inorganic salt was removed by centrifugation, the residue was recrystallized from hexane (1 mL) at –30 °C to give **4** (42 mg, 41%) as orange crystals; m.p. 287 °C. $^1$H NMR (400 MHz, $C_6D_6$): $\delta$ = 0.26 (s, 3 H, *t*$Bu_2$*Me*Si), 0.30 (s, 3 H, *t*$Bu_2$*Me*Si), 0.32 (s, 6 H, *t*$Bu_2$*Me*Si), 1.18 (s, 18 H, *tBu*$_2$MeSi), 1.19 (s, 18 H, *tBu*$_2$MeSi), 1.23 (s, 18 H, *tBu*$_2$MeSi), 1.24 (s, 18 H, *tBu*$_2$MeSi), 5.29 (s, 5 H, $C_5H_5$) ppm. $^{13}$C NMR (100.6 MHz, $C_6D_6$): $\delta$ = –3.7 (2 C), –3.5, –2.9,

21.2, 21.26, 21.31, 21.9, 30.2, 30.32, 30.34, 30.4, 79.7 ppm. $^{29}$Si NMR (79.5 MHz, $C_6D_6$): $\delta$ = –13.7 (1 skeletal Si), 22.0 (2 Si), 24.1, 32.1 (substituents Si), 43.5 (2 skeletal Si) ppm. UV/Vis (THF): $\lambda$ ($\varepsilon$) = 295 (14000), 410 (2100), 464 (770) nm. $C_{41}H_{89}CoGeSi_7$ (910.28): calcd. C 54.10, H 9.85; found C 53.79, H 9.74.

**($\eta^5$-Cyclopentadienyl)[$\eta^4$-tetrakis(di-*tert*-butylmethylsilyl)trisilagermacyclobutadiene]cobalt {[$\eta^4$-(*t*Bu$_2$MeSi)$_4$Si$_3$Ge]CoCp} (4) by Reaction of K$^+_2$·[R$_4$Si$_3$Ge]$^{2-}$ (R = SiMe*t*Bu$_2$) and [Cp$_2$Co]$^+$·[PF$_6$]$^-$:** The dipotassium salt of the trisilagermacyclobutadiene dianion, K$^+_2$·[R$_4$Si$_3$Ge]$^{2-}$ (R = SiMe*t*Bu$_2$) (**3**) (129 mg, 0.112 mmol), and [Cp$_2$Co]$^+$·[PF$_6$]$^-$ (38 mg, 0.114 mmol) were placed in a reaction tube with a magnetic stirring bar. Oxygen-free dry toluene (2 mL) was introduced by vacuum transfer, and the reaction mixture was stirred at room temperature to give an orange solution within 0.5 h. Then the solvent was removed in vacuo, and dry hexane was introduced. After inorganic salt was removed by centrifugation, the residue was recrystallized from hexane to give **4** (63 mg, 62%) as orange crystals.

**X-ray Diffraction Studies and Crystal Data for 2:** A single crystal of **2** suitable for X-ray diffraction study was grown from a hexane solution. The diffraction data were collected with a MacScience DIP2030 image plate diffractometer equipped with a rotation anode using graphite-monochromatized Mo-$K_\alpha$ radiation ($\lambda$ = 0.71070 Å) at 150 K. The structure was solved by direct methods using the SIR-92 program[11] and refined by full-matrix least-squares methods using the SHELXL-97 program.[12] Crystal data: $C_{41}H_{89}CoSi_8$, $M$ = 865.77, orthorhombic, *Pccn*, $a$ = 19.1700(5), $b$ = 15.8280(9), $c$ = 17.1620(10) Å, $V$ = 5207.3(4) Å$^3$, $Z$ = 4, $D_{calcd.}$ = 1.104 g/cm$^3$, $R$ = 0.0437 ($wR$ = 0.1259 for all data) for 6260 reflections with $I > 2\sigma(I)$, $GOF$ = 0.924. CCDC-659562 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# New Polymorphs of Magnesium-Based Metal–Organic Frameworks $Mg_3(ndc)_3$ (ndc = 2,6-Naphthalenedicarboxylate)

**Irena Senkovska,[a] Julia Fritsch,[a] and Stefan Kaskel*[a]**

**Keywords:** Metal–organic frameworks / Magnesium / 2,6-Naphthalenedicarboxylic acid / Solvent effects / Gas adsorption

Two new magnesium 2,6-naphthalenedicarboxylate (ndc) metal–organic frameworks, $[Mg_3(ndc)_3(dif)_4]$ (**1**) (dif = *N*,*N*-diisopropylformamide) and $[Mg_3(ndc)_3(dmf)_2(CH_3OH)(H_2O)](dmf)$ (**2** = TUDMOF-3) (dmf = *N*,*N*-dimethylformamide), have been synthesised under solvothermal conditions from $Mg(NO_3)_2{\cdot}6H_2O$ and pure 2,6-naphthalenedicarboxylic acid. According to single-crystal X-ray crystallographic studies, complex **1** crystallises in the space group $P2_1/n$ [$a$ = 14.769(3) Å, $b$ = 13.325(3) Å, $c$ = 17.998(4) Å, $\beta$ = 108.67(2)°] and complex **2** in the space group $P\bar{1}$ [$a$ = 11.1116(11) Å, $b$ = 12.6229(13) Å, $c$ = 17.800(2) Å, $\alpha$ = 88.568(14)°, $\beta$ = 83.833(13)°, $\gamma$ = 70.167(11)°]. The structures of compounds **1** and **2** consist of trinuclear magnesium clusters connected to six dicarboxylate ligands; for **2**, the clusters act as distorted octahedral nodes to give a 3D network. In contrast, the trinuclear clusters in **1** act as pseudo-planar-hexagonal nodes to give a 2D network assembly. According to nitrogen and hydrogen physisorption measurements at 77 K for compounds **1** and **2**, TUDMOF-3 has a permanent porosity with a Langmuir surface area of 632 $m^2 g^{-1}$, a specific pore volume of 0.21 $cm^3 g^{-1}$ and a hydrogen storage capacity of 1.23 wt.-% at 77 K and 1 bar, whereas compound **1** is not porous.

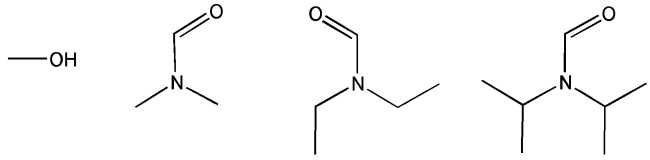
## Introduction

Metal–organic frameworks (MOFs) are compounds in which organic multifunctional molecules act as linkers to interconnect metal ion or multinuclear complex (cluster) nodes into a 3D network of predefined topology.[1–6] MOFs are a relatively new class of microporous materials that show promise for diverse applications because of their high porosity, tunable pore size and functionality.[7–10]

2,6-Naphthalenedicarboxylate (ndc) is an adequate molecular linker for the construction of coordination polymers because of its rigidity and stability. Recently, several interesting examples of MOF structures containing ndc were discovered: $[Al(OH)(ndc)(H_2O)]$ (MIL-69),[11] $[M(ndc)(H_2O)]$ (M = Mn, Zn or Cd),[12,13] $[Yb_2(ndc)_3(H_2O)_3]$,[14] $[M_2(OH)_2(ndc)]$ (M = Zn or Co),[15,16] $[M_2(ndc)_3(dmf)_4](H_2O)_m$ (M = Eu, Tb or Ce),[17] $[M(ndc)(H_2O)_m]$ (M = Ni or Co),[13,16] $Zn_6(ndc)_5(OH)_2(dmf)_6$ (MOF-48)[18] and $Zn_4O(ndc)_3$ (IRMOF-8).[10] The MOFs based on light metals such as Li, Mg and Al have recently received more attention. Constructing light-metal-based MOFs should allow the formation of lightweight materials that can be useful in gas storage applications.[19]

In a previous paper, we have reported a Mg-ndc-based MOF, $[Mg_3(ndc)_3(dmf)_4]$ (TUDMOF-2), and have shown that the pore size of the $Mg_3(ndc)_3$ networks can be adjusted by using different solvents (dmf, def).[20] In fact, TUDMOF-2 has the same network topology as $[Mg_3(ndc)_3(def)_4]$,[21] but the smaller solvent molecules induce the widening of pores, which leads to a larger specific surface area (SSA). In order to verify this concept, we have studied other solvents with smaller and larger diameters (Scheme 1).



Scheme 1. The solvents used for pore size adjustment in $Mg_3(ndc)_3$.

In the following, we describe the structure of two new magnesium carboxylates, $[Mg_3(ndc)_3(dif)_4]$ (**1**) and $[Mg_3(ndc)_3(dmf)_2(CH_3OH)(H_2O)](dmf)$ (**2** = TUDMOF-3) (*Technical University Dresden Metal–Organic Framework No. 3*), which are also constructed from Mg clusters and 2,6-naphthalenedicarboxylate linkers.

## Results and Discussion

### Synthesis and Structural Characterisation of 1 and 2

The solvothermal reaction of $Mg(NO_3)_2{\cdot}6H_2O$ and $H_2ndc$ in dif at 383 K results in the formation of yellow

crystals of **1**. For the same reaction carried out in dmf/$CH_3OH$ (1:1) solution, colourless crystals of **2** were obtained.

Complex **1** crystallises in the monoclinic space group $P2_1/n$ and contains two crystallographically independent magnesium atoms (Mg1 and Mg2). Mg1 and one of the two independent $ndc^{2-}$ anions are located at a general position. Mg2 and the middle of the central C–C bond in the naphthalene system in the second anion are positioned on crystallographic centres of inversion. The three magnesium atoms in **1** form a perfectly linear $[Mg_3(\mu_3\text{-}O)_2(\mu_2\text{-}O)_4]$ unit with $C_1$ symmetry (Figure 1a).

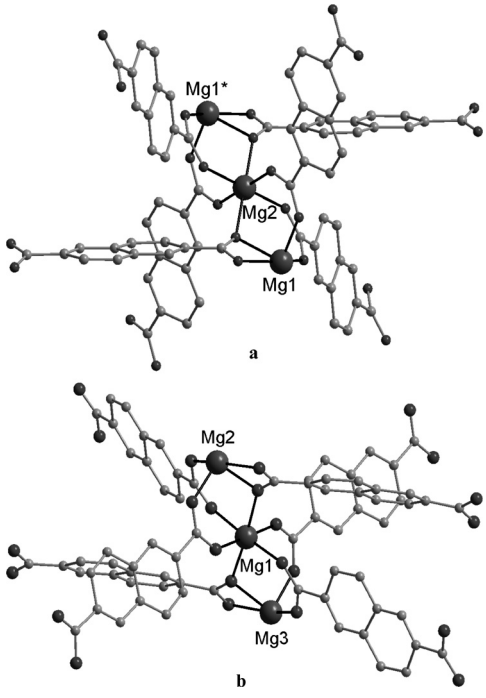

Figure 1. Trinuclear Mg carboxylate clusters and representation of the inorganic six-coordinate SBUs in **1** (a) and in **2** (b). Symmetry operation (*): $-x$, $-y$, $-z$.

The $[Mg_3(\mu_3\text{-}O)_2(\mu_2\text{-}O)_4]$ unit can be regarded as a secondary building unit (SBU). This trinuclear unit is a successful SBU, through which many interesting structures have been constructed in the past decade.[14,22–25] It should be noted that the trinuclear SBU is the most important Mg cluster, because the same structural motif was found in all Mg MOFs with a rigid 3D framework and permanent porosity reported so far.[20,21,25–29] Obviously, this SBU plays a key role in the formation of 3D networks in magnesium coordination polymers and a study of the multinuclear magnesium complexes assumes considerable importance.

The trinuclear magnesium clusters in **1** are connected by rigid organic linkers (ndc). The ndc ligands in compound **1** adopt two coordination modes that connect two Mg atoms: a bidentate bridging mode and an asymmetric chelating bridging mode. Consequently, a 2D layered MOF with triangular meshes and a $3^6$ topology is formed (Figure 2b). The Mg–O(carboxylate) distances for the terminal Mg1 atoms are in the range 1.997(3)–2.180(3) Å, whereas the Mg–O(carboxylate) distances for the central Mg2 atom are between 2.046(3) and 2.123(3) Å.

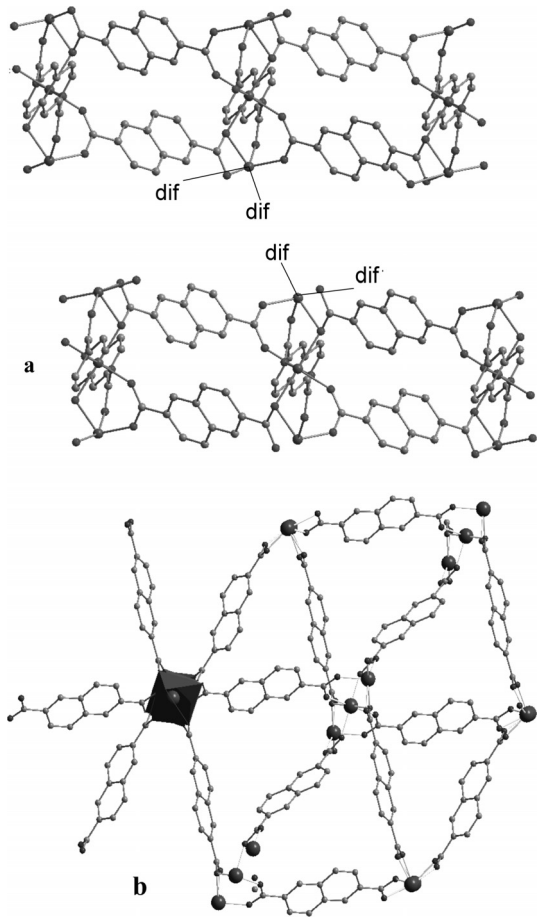

Figure 2. (a) The layer structure of **1** viewed along the crystallographic $b$ axis (the dif molecules are presented schematically); (b) the $3^6$ 2D layer network of **1** (coordinated dif molecules are not shown).

The thickness of the layer, given by the Mg–Mg distance between the terminal Mg atoms in the same SBU, is 7.15(1) Å, and the distance between two adjacent layers, given by the Mg–Mg distance between the terminal Mg atoms in neighbouring SBUs, is 9.48(1) Å (Figure 2a).

Two of the four dif molecules coordinated to a trinuclear cluster protrude into the triangular cavities, whereas the other two dif molecules fill the space between the layers, thereby separating two adjacent layers; therefore, the existence of the 2D network can be explained by the dif-induced steric hindrance that prevents the formation of coordinative bonds between adjacent SBUs and in this way prevents the formation of the 3D network too.

Single-crystal X-ray diffraction analysis reveals that compound **2** has essentially the same SBU (Figure 1b); the difference is that all three Mg atoms are located at a general position, and the SBU has no higher symmetry. Consequently, the cluster loses the perfect linearity and the Mg2–Mg1–Mg3 angle in this case is 176.75(1)°. The Mg2–O(carboxylate) distances range from 2.022(3) to 2.205(3) Å,

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

the Mg3–O(carboxylate) distances are between 1.967(3) and 2.188(3) Å, and the central Mg1–O(carboxylate) distances are between 2.038(4) and 2.118(4) Å.

The eight six-coordinate SBUs in **2** are interlinked through the $ndc^{2-}$ anions to form a highly distorted cubic network (Figure 3). One methanol and one dmf molecule are bound to Mg3 and one water and one dmf molecule are bound to Mg2 to give six-coordinate magnesium atoms. The solvent molecules in **2** can be removed to give a porous network having open magnesium sites. A summary of crystal data and structure refinement is provided in Table 2.

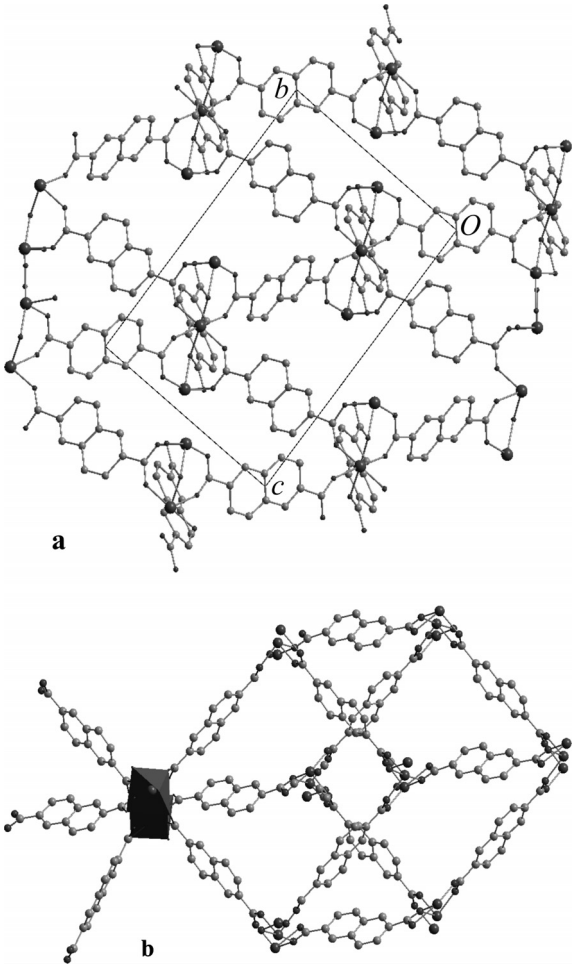

Figure 3. Extended structure of **2**: (a) viewed along the crystallographic *a* axis; (b) the 3D distorted cubic network cell of **2** (solvent molecules are omitted in both cases).

## Thermogravimetric Analysis

The thermogravimetric analysis (TGA) of **1** shows continuous weight loss in the temperature range from 330 to 790 K. The weight loss of 42.1% observed from 330 to 680 K can be attributed to the loss of four coordinated dif molecules (expected weight loss: 41.94%). The linker starts to decompose at 680 K.

A weight loss for **2** occurs between 398 and 693 K corresponding to the loss of dmf, $CH_3OH$ and $H_2O$ solvent molecules (observed: 28.0%, calculated: 27.35%), followed by the decomposition of the ligand in the temperature range 758–918 K. The weight loss is consistent with the elemental analysis and the empirical formula deduced from the single-crystal X-ray crystallographic analysis.

## Evacuated Frameworks and Sorption Properties

All materials were evacuated under vacuum and heated to 423 K. The desolvated $Mg_3(ndc)_3$ framework of $[Mg_3(ndc)_3(dmf)_2(CH_3OH)(H_2O)](dmf)$ is hereafter denoted as **2a**. The powder XRD pattern of **2** changes after removal of the guest molecules relative to that of the as-synthesised product (Figure 4a). A similar behaviour of the framework was observed for TUDMOF-2. But in the case of TUDMOF-3 the original framework of **2** could not be regenerated through a treatment of **2a** with dmf or a dmf/$CH_3OH$ mixture. According to XRD analysis (Figure 4b), a new unknown structure can by identified as a result of the resolvation. This compound has no porosity.

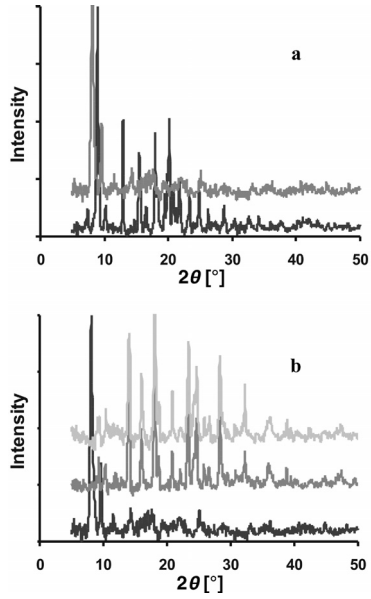

Figure 4. X-ray powder diffraction patterns (a) for **2** as synthesised (black) and **2** desolvated (grey); (b) for **2** desolvated (black), **2** resolvated with dmf (dark grey) and **2** resolvated with dmf/$CH_3OH$ (1:1) (light grey).

Gas-sorption properties of **1** and **2** were examined by measuring $N_2$ and $H_2$ adsorption isotherms at 77 K. Significant differences between **1** and **2** were observed in the gas-adsorption properties. The $N_2$ isotherms for **2** display typical type-I adsorption characteristics (Figure 5a).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

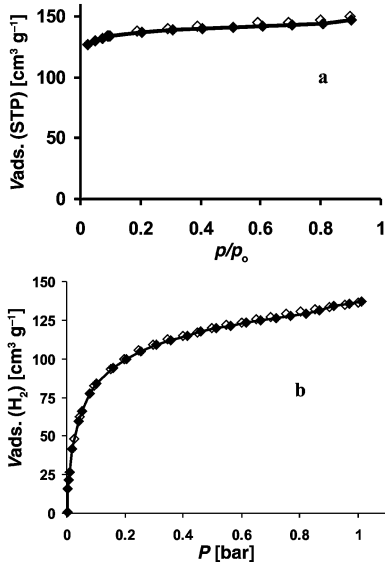

Figure 5. (a) The $N_2$ adsorption (solid symbols) and desorption (empty symbols) isotherms of **2** at 77 K; (b) $H_2$ adsorption (solid symbols) and desorption (empty symbols) isotherms of **2** at 77 K.

The Brunauer–Emmett–Teller (BET) surface areas of the solvent-free frameworks of **2** were estimated to be 418 $m^2 g^{-1}$ at 0.3 $p/p_0$. The sorption isotherm was also fitted to a Langmuir equation; the resulting specific surface area is 623 $m^2 g^{-1}$. The micropore volume obtained from nitrogen adsorption at 77 K and 0.2 $p/p_0$ is 0.21 $cm^3 g^{-1}$. The hydrogen adsorption isotherm for **2** measured at 77 K is given in Figure 5b. The maximum $H_2$ uptake of **2** is 1.23 wt.-% at 1 bar. Compound **1** is essentially nonporous; it has only a low $N_2$ adsorption capacity and a type-II adsorption isotherm.

### The Role of Solvent

It was shown that the use of def, dmf or dmf/$CH_3OH$ mixtures as solvents in the solvothermal reaction of $Mg(NO_3)_2 \cdot 6H_2O$ and $H_2$ndc leads to the formation of three different porous compounds, $Mg_3(ndc)_3(def)_4$, $Mg_3(ndc)_3(dmf)_4$ (TUDMOF-2) or $[Mg_3(ndc)_3(dmf)_2(CH_3OH)(H_2O)](dmf)$ (TUDMOF-3), respectively. The networks formed have identical topology, but the minor structural differences (lattice constants) influence the sorption properties of the materials. Several reactions were carried out to elucidate the influence of the solvent mixture composition on the formation of the different compounds. $Mg(NO_3)_2$ and $H_2$ndc were treated at 110 °C for 24 h with varying proportions of def (or dmf) and $CH_3OH$ (or $C_2H_5OH$) (Table 1). The products were identified by powder X-ray diffraction analysis.

In the case of solvent mixtures containing def and dmf, the resulting product is a compound incorporating only one type of solvent. In the case of mixed-solvent solutions containing dmf and methanol, TUDMOF-3 was obtained as the main product. If dmf or def is mixed with ethanol (1:1), then the compound containing only formamide is obtained.

Table 1. The role of solvent in defining the product from the solvothermal reaction of $Mg(NO_3)_2$ and $H_2$ndc at 383 K.

| Solvent | Solvent ratio [%] | Product |
|---|---|---|
| def | 100 | $Mg_3(ndc)_3(def)_4$ |
| dmf | 100 | $Mg_3(ndc)_3(dmf)_4$ |
| dmf + $C_2H_5OH$ | 50:50 | $Mg_3(ndc)_3(dmf)_4$ |
| def + $C_2H_5OH$ | 50:50 | $Mg_3(ndc)_3(def)_4$ |
| dmf + $CH_3OH$ | 50:50 | $[Mg_3(ndc)_3(dmf)_2(CH_3OH)(H_2O)](dmf)$ |
| dmf + def | 25:75 | $Mg_3(ndc)_3(def)_4$ |
| dmf + def | 50:50 | $Mg_3(ndc)_3(dmf)_4$ |
| dmf + def | 75:25 | $Mg_3(ndc)_3(dmf)_4$ |

Furthermore, the hydrothermal treatment of TUDMOF-2 or $Mg_3(ndc)_3(def)_4$ in def or dmf, respectively, did not convert one into the other; thus, a given network retains its structure irrespective of the postsynthetic solvothermal treatment.

## Conclusion

In summary, TUDMOF-3 has the same network topology as TUDMOF-2, but the occlusion of smaller solvent molecules induces significant structural changes resulting in a different space group and higher specific surface area. On the other hand, the larger solvent molecule in **1**, dif, hinders the formation of a 3D network, resulting in a 2D double-layered structure. The solvent plays a key role in the construction of the networks and predetermines the formation of a certain product. The selection of the solvent or solvent mixture demonstrates the potential for pore size adjustment in metal–organic frameworks.

## Experimental Section

**General Remarks:** All reagents and solvents (reagent-grade) were used as received. Elemental analyses (C, H, N) were performed by the Elemental Analysis Service, Institute of Organic Chemistry, Dresden University of Technology. Powder X-ray diffraction (PXRD) data were collected by using a Stoe STADI P powder diffractometer with Cu-$K_{\alpha 1}$ radiation. Thermogravimetric analyses (TGA) were carried out by using a Netzsch STA 409 thermal analyser with heating in air at 10 K $min^{-1}$ to 1273 K. Physisorption isotherms were measured at 77 K with a Quantachrome Autosorb1C apparatus. High-purity gases were used (nitrogen: 99.999%, hydrogen: 99.999%). Prior to the measurement, the samples were evacuated for 16 h at 423 K. The specific surface areas and porosity parameters were derived from the $N_2$ adsorption data.

**X-ray Crystallography:** Single-crystal X-ray diffraction data for complexes **1** and **2** were recorded with a STOE IPDS I image plate diffractometer by using Mo-$K_\alpha$ radiation. The structures were solved by direct methods with the help of SHELXS-86[30] and refined by full-matrix least-squares techniques with SHELXL-97.[31] Non-hydrogen atoms were refined with anisotropic temperature parameters. The hydrogen atoms of the $CH_3$ groups and aromatic

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

hydrogen atoms were positioned geometrically and refined by using a riding model; the remaining hydrogen atoms were located from the difference Fourier maps. Further details of the structural analysis are summarised in Table 2. CCDC-650990 (for **1**) and -650991 (for **2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

### Preparation and Characterisation

**$[Mg_3(ndc)_3(dif)_4]$ (1):** 2,6-Naphthalenedicarboxylic acid (0.16 g, 0.75 mmol) was dissolved in dif (10 mL). $Mg(NO_3)_2{\cdot}6H_2O$ (0.26 g, 1.0 mmol) was added to this solution. The mixture was filled into a 40-mL Teflon liner and was heated in an autoclave at 383 K for 20 h. It was then cooled to room temperature at a rate of 0.05 K min$^{-1}$ to produce large crystals of **1**, which were suited for X-ray analysis. Yield: 0.10 g (32.5%). $Mg_3C_{64}H_{78}N_4O_{16}$ (1232.23): calcd. C 62.38, H 6.38, N 4.55; found C 62.10, H 6.37, N 4.52.

**$[Mg_3(ndc)_3(dmf)_2(CH_3OH)(H_2O)](dmf)$ (2):** A mixture of $Mg(NO_3)_2{\cdot}6H_2O$ (0.52 g, 2.0 mmol) and 2,6-naphthalenedicarboxylic acid (0.32 g, 1.4 mmol) in dmf (20 mL) and $CH_3OH$ (20 mL) was filled into a 250-mL Teflon liner. The mixture was heated in an autoclave at 383 K for 24 h, then cooled to room temperature at a rate of 0.05 K min$^{-1}$. The resulting colourless crystals were collected, washed with methanol and dried under argon to give **2**. Yield: 0.36 g (73.5%). $Mg_3C_{46}H_{45}N_3O_{17}$ (984.78): calcd. C 56.10, H 4.61, N 4.27; found C 55.46, H 4.62, N 4.22.

# Direct Synthesis of Zr-Containing Hybrid Periodic Mesoporous Organosilicas with Tunable Zirconium Content

**Shang-Ru Zhai,[a] Sung Soo Park,[a] Mina Park,[a] M. Habib Ullah,[a] and Chang-Sik Ha*[a]**

**Keywords:** Silicates / Template synthesis / Orangic–inorganic hybrid composites / Mesoporous materials

Highly ordered Zr-containing periodic mesoporous organosilicas (ZrPMO) with different Zr/Si ratios were successfully synthesized, for the first time, by employing a $ZrOCl_2$/NaCl combination as the promoting agent and by simply adjusting the molar ratio of the zirconium species to the organosilica precursor; no addition of mineral acids was necessary. The effect of preparation parameters on the structural and textural properties were carefully investigated by using different ratios of NaCl/Si and Zr/Si. It was found that both salts are essential for this system and highly ordered ZrPMOs can be prepared within fairly wide Si/Zr ratios (5–100) while keeping the NaCl/Si ratio constant. To prove the effectiveness of this synthetic pathway with a higher Zr incorporation, ZrPMO materials were also synthesized under strongly acidic conditions for the purpose of comparison. The synthesized ZrPMO materials were thoroughly characterized by ICP-AES, SAXS, $N_2$ sorption, TEM, SEM, $^{13}C$ CP/$^{29}Si$ MAS NMR spectroscopy, XPS, and TGA. Elemental analyses show that the amount of Zr incorporated into ZrPMO, which was synthesized under mild conditions, is greater than that obtained in a strongly acidic environment, and the Zr content, with a Si/Zr ratio up to 12, is close to that in the initial gel composition. A plausible assembly mechanism based on the synergistic effect of both "nonhydrolyzable" (NaCl) and "hydrolyzable" ($ZrOCl_2$) inorganic salts was discussed in detail, where the "salting out" effect and self-generated acidity from both inorganic salts, respectively, are believed to be key factors for the formation of ordered SBA-15-type ZrPMO materials under the synthetic conditions.

## Introduction

Since its first synthesis in 1999,[1–3] periodic mesoporous organosilica (PMO) materials have attracted increasing research attention in the field of ordered mesoporous materials. These novel hybrid materials, characterized with the high organic content incorporated within the framework, were synthesized by the hydrolysis and condensation of bis(trialkoxysilyl)alkylsilanes such as $(R'O)_3Si\text{-}R\text{–}Si(R'O)_3$ with the aid of structure-directing agents.[1–4] The fascinating properties featured by these materials include highly ordered structures and uniform pore-size distributions within a framework formed by a homogeneous distribution of organic fragments and inorganic oxide. In comparison with their inorganic counterparts, these hybrid mesostructures offer unique advantages and enormous possibilities that are closely associated with the characteristics of the organic polymers, such as tunable interfacial and physicochemical properties, by simply varying the organic bridging groups embedded within the mesoporous framework. With the aforementioned advantages, PMO materials are promising candidates in the fields of catalysis, selective adsorption, chromatography, low-*k* devices, or host–guest chemistry.

At present, PMO materials with various framework bridging groups ranging from small aliphatic spacers to aromatic and large heterocyclic ones were successfully synthesized.[5–15] Recently, the synthesis of bi- and multifunctional PMOs has become a hot research topic in this field, because proper selection of these groups allows one to design functional nanocomposites for specific catalytic and environmental applications.[16–21] The synthesis of these materials has been carried out by using cationic, anionic, and nonionic oligomeric and copolymeric surfactants under basic or acidic conditions.

Although the development of PMOs has opened new opportunities in the field of mesoporous materials, there is still a lack of application of these materials to the field of catalysis. Thus, unlike in the case of inorganic mesostructured materials upon which many different heteroatoms have been supported in the hope to discover catalytic properties, only a few examples have been reported on the functionalization of PMOs with the use of heterometallic atoms. Most of them use the organic functionality as a ligand to bind the

 WILEY InterScience DISCOVER SOMETHING GREAT © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

metallic atoms,[22,23] but these procedures are only appropriate for a small amount of metal atom–organic functionality pairs. The second strategy used for synthesizing these metal-functionalized PMOs involves direct synthetic procedures through the isomorphic substitution of the silicon atoms by the metal species of interest. In most cases, however, this procedure has only successfully been applied to the heterogenization of limited metal species in the synthesis of hexagonally packed PMO materials by using cationic surfactants.[24–32] For instance, aluminum was incorporated within the mesoporous framework of ethanesilicas by a direct synthetic method with the use of cationic surfactants under basic conditions.[24–26] The resultant hybrid mesostructures showed a high hydrothermal stability that can be attributed to the presence of hydrophobic ethane bridging groups distributed within the whole framework. Furthermore, this highly hydrophobic character improved the catalytic behavior in alkylation reactions in comparison with that shown by AlMCM-41 materials.[24] Likewise, titanium, chromium, vanadium, and other species have also been incorporated into the structure of ethane-bridged PMO materials, and these obtained materials showed a good degree of incorporation of the metal functionality.[27–33] In these works, it was reported that Ti-containing PMO materials are highly hydrophobic and fairly efficient in the epoxidation of α-pinene,[27] epoxidation of propene into propene oxide in the vapor phase,[28] and ammoxidation of ketones to oximes.[29] Apparently, the enhanced catalytic efficiency was directly associated with the framework hydrophobicity of these hybrid catalysts. Among these limited reports,[24–33] however, only one paper was devoted to the synthesis of SBA-15-type PMO from titanocene dichloride by using copolymeric surfactant under acidic conditions, and these hybrid catalysts showed good performance in the epoxidation of 1-octene with hydroperoxides.[33] Currently, there is a quest for large-pore hybrid PMO materials from the point of view of immobilization or transformation of bulky molecules; therefore, these results have prompted us to take a step forward in the synthesis of metal-functionalized PMO materials with large pore diameters.

In the present study, we report an effective and convenient synthetic pathway to zirconium-functionalized periodic mesoporous organosilicas (PMOs) by employing a $ZrOCl_2$/NaCl combination as the promoting agent under acid-free conditions. This is, to the best of our knowledge, the first example of SBA-15-type ZrPMO with tunable Zr content synthesized by simply adjusting the molar ratio of Zr/Si while retaining another NaCl/Si ratio constant. The resultant materials were characterized and have excellent structural ordering, narrow pore-size distributions, and hybrid organic–inorganic frameworks; meanwhile, these characterization results indicate that both inorganic salts are essential to the formation of ordered ZrPMO materials. More desirably, this novel synthetic system is more advantageous in comparison to the HCl-assisted synthetic pathway either from the point of view of zirconium incorporation or the structural properties of the obtained ZrPMO materials.

## Results and Discussion

### Effect of Both NaCl/Si and Zr/Si Molar Ratios

As reported, since its first synthesis in 1998,[34] SBA-15-type materials have been extensively studied.[35] However, it is difficult to synthesize Zr-incorporated SBA-15 silicas with a high amount of Zr loading, because the Zr–O–Si bonds are easily dissociated; this is due to the hydrolysis of zirconium precursors under the strongly acidic hydrothermal preparation conditions. However, by decreasing the acidity of the synthetic system to balance the hydrolysis rate of Zr precursors with that of the silicon precursors, the interaction between the Zr–OH and Si–OH species in the synthesis gels could be effectively enhanced, which would result in a higher amount of Zr ion incorporated in the framework of SBA-15-type materials. Therefore, by following our previous studies,[7,36] this paper reports an effective direct synthesis of a higher amount of Zr incorporated in the SBA-15-like PMO materials by employing a $ZrOCl_2$/NaCl combination as the promoting agent under acid-free conditions, and the Zr content loaded in the PMO materials is tunable by simply adjusting the Si/Zr molar ratios from 5 to 100 in the synthesis gels while keeping the NaCl/Si ratio constant.

To prove the importance of the salt combination during the synthesis, the effect of both NaCl/Si and Si/Zr ratios were thoroughly investigated. With Si/Zr = 10 for all samples, the variation of the SAXS patterns as a function of the NaCl/Si ratios is illustrated in Figure 1. Well-defined SAXS patterns are clearly observed for those samples synthesized with NaCl/Si ratios varied from 1–6, similar to those recorded for all SBA-15-type materials as described by Zhao et al.[34,35] The SAXS patterns of these samples exhibit at least three well-resolved peaks, which can be indexed to the (100), (110), and (200) reflections of the hexagonal space group *p6mm*. Among these samples, however, the optimal structural ordering of the hexagonal mesostructure was obtained for the sample synthesized with a NaCl content around NaCl/Si = 4, which is evidenced by the reflection intensity that decreased as the NaCl/Si ratios increased or decreased relative to this point. This observation is reminiscent of the previous results for large-pore PMOs, which proved that highly ordered mesostructures were successfully prepared in the presence of a large amount of Na(K)Cl salts.[7,37]

Therefore, the ratio of NaCl/Si was fixed at 4 in the following experiments that allowed the study of the effects of the Si/Zr molar ratios on the synthesis; Figure 2 shows the SAXS patterns of samples synthesized with different Si/Zr ratios varied from 5–100. With only one exception from that prepared without zirconium salt, all other patterns of the extracted PMOs exhibit very sharp reflections, which clearly indicates a high degree of structural ordering. Likewise, the reflections can be indexed as (100), (110), and (200) peaks according to the 2D hexagonal symmetry of the materials.[34] The results strongly reveal the effectiveness of this synthetic method irrespective of the fairly wide range of Zr/Si ratios, which is somewhat similar to the studies

reported recently where highly ordered SBA-15-like PMO materials were facilely prepared within a wide composition range by employing a KCl-assisted low-acid-concentration synthetic pathway.[37] By combining the SAXS data (Figures 1 and 2), we can clearly see that the combination of $ZrOCl_2$/NaCl is indispensable for this synthesis, that is, highly ordered PMO materials are easily achievable with a variable zirconium salt amount while keeping the NaCl/Si ratio constant; this fascinating observation has never been reported for large-pore PMO materials templated by block copolymer surfactants.

To further prove the important effect of this salt combination on the structural ordering of the resultant materials, a series of samples were also synthesized by using various acid concentrations for comparison purpose, where the zirconium salt amount with Si/Zr = 10 is constant through all experiments. Figure 3 shows that the samples synthesized with 0.4 and 1.0 M HCl exhibit a single peak together with a broad shoulder and another one from 0.2 M HCl only possesses a very broad peak. Such reflection patterns are often observed for wormhole-like mesostructures, in agreement with our previous results that disordered PMOs were commonly obtained under strong acidic conditions without the assistance of NaCl.[7] In contrast, the fact that a highly ordered sample can be easily synthesized by using the $ZrOCl_2$/NaCl pair without the addition of any mineral acids further indicates that this salt combination is very effective for the assembly of ordered organosilica–surfactant nanocomposites, even though the amount of zirconium salt added in the reaction gels is quite small; a plausible formation mechanism will be discussed below.

The zirconium contents in the PMO materials synthesized by using both salt pair and HCl solutions were determined by ICP-AES and XPS techniques, and the results are summarized in Table 1. The former technique provides the elemental analysis of the bulk sample, whereas the latter gives the surface composition information. The atomic ratios of Si/Zr in the solids synthesized by using $ZrOCl_2$/NaCl were found to be slightly larger than that in the synthesis gels. These results might be due to variations in zirconium leaching during the extraction processes by using acidified ethanol. It was reported that this phenomenon is common to directly synthesized metal-incorporated hybrid frameworks where the complete removal of surfactant is relatively more difficult due to the enhanced interaction between the surfactant and the metal species.[38,39] However, the zirconium content in the above-described materials is consider-

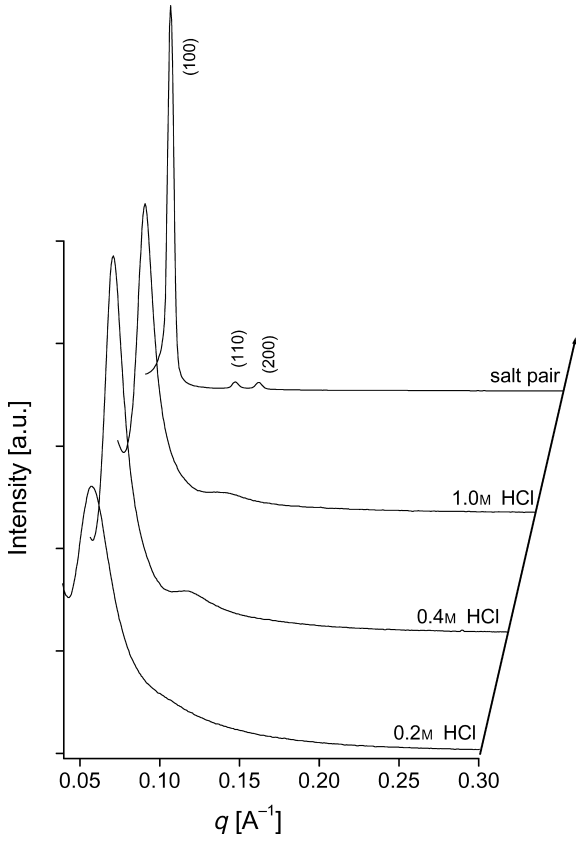

Figure 3. SAXS patterns of PMO materials synthesized by using different HCl concentrations, here the Si/Zr molar ratio is 10 for all samples.

ably higher than that of the samples synthesized with HCl solutions especially for those obtained with 0.4 or 1.0 M HCl, which is in agreement with the reported observations.[39] Noticeably, this synthetic pathway, that is, the use of $ZrOCl_2$/NaCl as the promoting agent, is not only more effective for the formation of highly ordered PMO materials but also more favorable for zirconium incorporation than the HCl-assisted synthesis, which can be considered the main advantage of this route.

In addition, the surface Si/Zr atomic ratios are, for representative materials synthesized from the $ZrOCl_2$–NaCl pair, significantly larger than that used in the synthesis (see Table 1). This is expected by taking into account that zirconium species may be mainly incorporated into the hybrid frameworks, and consequently, zirconium atoms are preferentially located at the interior pore surfaces.[40] In Figure 4, the O 1s, Zr 3d, and Si 2p core-level spectra for the sample

synthesized by using the salt pair with Si/Zr = 10 are presented as an example. The binding energy (BE) of O 1s (528.55 eV) was 1.65 eV lower than that given by oxygen in $ZrO_2$ (530.2 eV), and the binding energy of Zr 3d (179.1 eV) in this PMO material was also distinctly lower than that in $ZrO_2$ (181.9 eV). This significant shift indicated that no segregated oxide phase of zirconium was present,[40,41] which clearly supports the incorporation of zirconium into the hybrid framework. It should be noted, however, that the BE values for O 1s, Zr 3d, and Si 2p (98.65 eV) of this sample is considerably lower than that of the Zr-incorporated inorganic frameworks reported before,[40,41] which may be associated with the unique hybrid character of this PMO material. To the best of our knowledge, this is the first example of a preparation of highly ordered SBA-15-type ZrPMO materials with tunable framework zirconium content by the addition of inorganic salts and under such mild synthetic conditions.

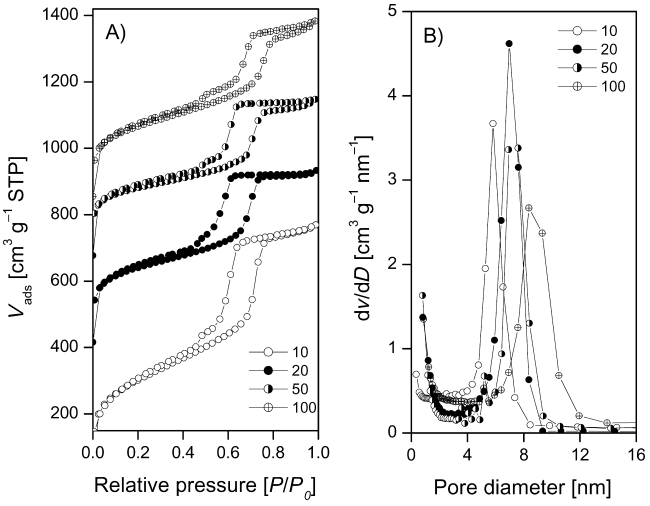

Figure 5. (A) Nitrogen adsorption isotherms and (B) BJH pore-size distributions of ZrPMO materials prepared by using the $ZrOCl_2$–NaCl combination with various Si/Zr molar ratios (as shown inset in the figures).

## Physical Properties

Figure 5 shows the nitrogen adsorption isotherms of the typical ZrPMO materials synthesized with different Si/Zr ratios by the $ZrOCl_2$–NaCl-assisted pathway. All samples exhibit a high degree of structural ordering, as indicated by the distinct capillary condensation step of the respective adsorption isotherm. This strongly suggests the presence of uniform cylindrical pores in these materials, in accordance with the 2D hexagonal pore structures revealed by the SAXS analysis and those reported results for SBA-15-like PMO or siliceous materials prepared under strongly acidic conditions.[7,34,42] Correspondingly, the pore-size distributions calculated from the adsorption branch clearly display a uniform pore structure for all samples (Figure 5B). The specific structural parameters derived from this sorption analysis such as total pore volumes, micropore volumes, pore sizes, and BET surface areas are summarized in Table 1. Noticeably, all ZrPMOs possess the typical structural properties of SBA-15-type materials such as large surface area and pore volume and a considerable amount of micropores,[34,42] and these textural features are comparable to those excellent SBA-15-like PMO or silica materials prepared from other synthesis systems.[7,34] Besides, it is interesting to note that a distinct relationship between the structural properties and preparation conditions can be drawn among these samples, that is, the specific surface areas and pore sizes clearly decrease and increase, respectively, with the Si/Zr ratios. All of these parameters indicate that the structural ordering, textural properties, and the incorporation of zirconium into the ZrPMO materials can be easily achieved by using different Si/Zr ratios by the synthesis pathway.

Consistent with the results of the SAXS and the physisorption measurements, respectively, the transmission electron microscopy (TEM) images of the representative samples viewed along different directions show well-ordered hexagonal arrays of 2D mesoporous channels (Figure 6), which further confirms that these samples are of *p6mm* hexagonal structure. Actually, no distinct difference can be found between this observation and that for P123-templated PMOs synthesized under various conditions such as such salt-assisted acidic synthesis[7,37] or the true-liquid-crystal-templating (TLCT) approach,[43] which strongly indicates the outstanding promoting effects of the salt pair in this synthetic system though the zirconium salt amount is very small; the function of both salts is entirely similar to that of reported Na(K)Cl/HCl combinations used for the synthesis of highly ordered mesostructures templated by block copolymers.[7,35,44,45]

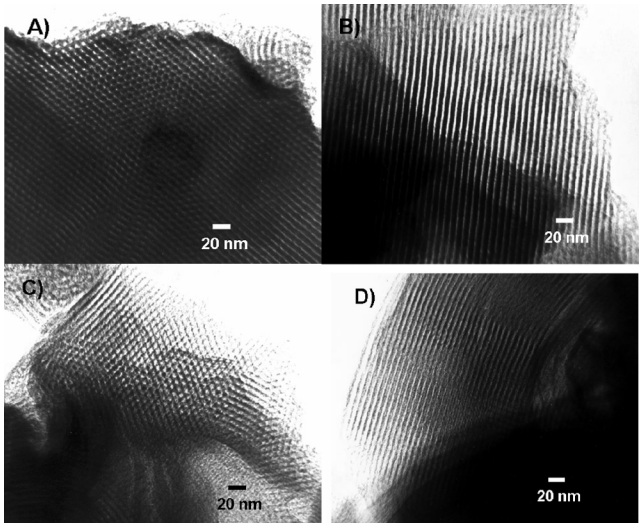

Figure 6. TEM micrographs of the samples synthesized by using the $ZrOCl_2$–NaCl pair with Si/Zr = 10 (A, B) and 100 (C, D).

The representative scanning electron microscopy (SEM) images for the ZrPMO materials synthesized with different Si/Zr ratios are shown in Figure S1 (Supporting Information). Clearly, no characteristic morphologies can be

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

found for all samples and irregular particles or aggregates are dominant through all the images, even though the particle/cluster size looks like it decreases with increasing Si/Zr ratios. Noticeably, these results are vastly different from those reported for SBA-15-type materials prepared under strongly acidic conditions, as described by Zhao et al., where wheat-like fibers composed of short rod-like particles were commonly observed.[34,42] This may be closely associated with the different preparation conditions (e.g. acidity, temperature, shear flow, ionic strength, etc.), which can exert a great impact on the hydrolysis and condensation kinetics of silica sources and therefore the morphological properties of the final mesophases.[34,46]

As far as this synthetic system is concerned, however, possibly there is no favorable orientation growth effect during the assembly process because of the fairly mild synthetic conditions. Under such conditions, the sol–gel kinetics of the organosilica precursor are so slow that the induction time for precipitation is too long to have a favorable effect on the macroscopic morphologies, even though this synthetic system is enough for the formation of ordered mesoporous frameworks. Actually, another observation directly confirmed the mildness of this synthesis system, that is, only less-ordered materials were obtained without stirring during the assembly process (see Figure S2); meanwhile, no distinct morphological variation was observed between both samples obtained with or without stirring during the synthesis (Figure S3). This result indicates that the shear flow is of great importance for the formation of highly ordered ZrPMO materials in this system due to the mild synthetic conditions, which is greatly different from the earlier work carried out in strongly acidic solutions.[47]

### Framework Properties

The $^{13}C$ cross-polarization (CP) and $^{29}Si$ MAS NMR spectra were used to clarify the basic structural information in these ZrPMO samples prepared with different Si/Zr ratios from the $ZrOCl_2$–NaCl-assisted synthesis. Interestingly, it was indeed found that there were no distinct differences in the spectra results between these samples, which indicates that the ethylene-bridging groups were completely intact in all samples, even though their framework compositions were different due to the variable zirconium content (see Table 1). For specific examples, Figure 7 shows the $^{13}C$ and $^{29}Si$ NMR spectra of two representative ZrPMO samples synthesized with Si/Zr = 10 and 100, respectively. In the case of the $^{13}C$ CP NMR spectra, a prominent peak is observed at 4.8 ppm for all samples, which is attributed to the ethylene carbon atoms covalently linked to the Si atoms in the framework.[7,8,43] Besides this, another three weak peaks at $\delta$ = 17.6, 57.8, and 70.1 ppm for the extracted samples can be assigned to the tiny amount of ethoxy ($-OC_2H_5$) groups exchanged during the extraction process and residual copolymer surfactant, respectively. However, in comparison with the sample prepared with Si/Zr = 100, a distinct peak due to the residual P123 is observed for the sample with a lower Si/Zr ratio of 10, though a similar extraction process was used for both samples. This result might be attributed to the presence of a relatively large amount of zirconium ions in the framework, which results in surfactant molecules that are more difficult to remove even under the identical extraction conditions.[38]

In addition, the $^{29}Si$ MAS NMR spectra of all samples exhibit two distinct signals at –56.5 and –64.0 ppm, which are attributable to the $T^2$ [C-*Si*(OH)$(OSi)_2$] and $T^3$ [C-*Si*$(OSi)_3$] silica species, respectively. Another very weak signal at –48.7 ppm due to the $T^1$ [C-*Si*$(OH)_2$(OSi)] silica environment is also observed. The strong intensity for the $T^2$ and $T^3$ signals indicates the formation of relatively condensed organosilicate frameworks for these samples; actually, there is no apparent difference between these materials and those prepared under strongly acidic conditions.[7,43]

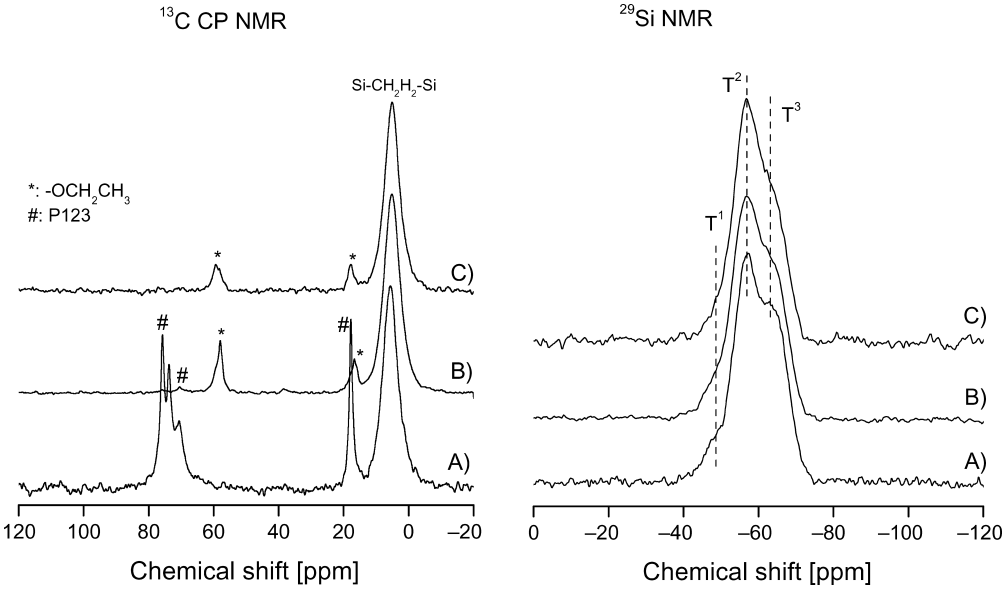

Figure 7. Solid-state $^{13}C$ CP and $^{29}Si$ MAS NMR spectra of the samples: (A) as-synthesized ZrPMO and (B) extracted ZrPMO obtained with Si/Zr = 10 by the salt-pair-assisted synthesis; (C) extracted ZrPMO prepared by using the similar method with Si/Zr = 100.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

The absence of $SiO_4$ species such as $Q^3$ [*Si*(OH)$(OSi)_3$] and $Q^4$ [*Si*$(OSi)_4$], which produce signals between –90 and –120 ppm, indicates that no carbon–silicon bond cleavage of the BTME precursors occurred during this mild synthesis. These combined analyses clearly demonstrate that all of the Si atoms in these ZrPMO materials are bonded covalently to carbon atoms. It should be noted, however, that no significant changes in the $^{29}Si$ NMR spectra due to the different zirconium content incorporated into the framework can be seen for these samples. This is also an indication that the local environment of silica species in these hybrid materials is totally irregular in nature, which is similar to the previous results reported for Zr-incorporated SBA-15 silicas.[39,48]

Thermogravimetric analysis (TGA) conducted in flowing air and the derivative plots of as-synthesized and extracted ZrPMO synthesized with Si/Zr = 10 by the synthetic pathway are depicted in Figure 8. For both profiles, the weight loss below 120 °C is due to the removal of the physically adsorbed water or ethanol exchanged during the extraction process. A main weight loss (ca. 38%) in the range of 180–450 °C is observed for the as-synthesized one, which can be mainly assigned to the decomposition/combustion of the copolymer surfactant molecules.[39] After extraction, however, the weight loss (ca. 7%) observed in the same region appears too large to be attributed solely to the residual P123 surfactant, that is, there should be some contribution from the framework ethylene groups, which is consistent with the reported results[43,49] and the aforementioned $^{13}C$ CP NMR spectroscopic analysis that only a tiny amount of residual surfactant molecules were detected. However, it should be pointed out that the decompositions of the ethylene bridging groups is not only limited to this region, the weight loss over the range of 260–650 °C should be principally attributed to their removal under the present working conditions.[43]

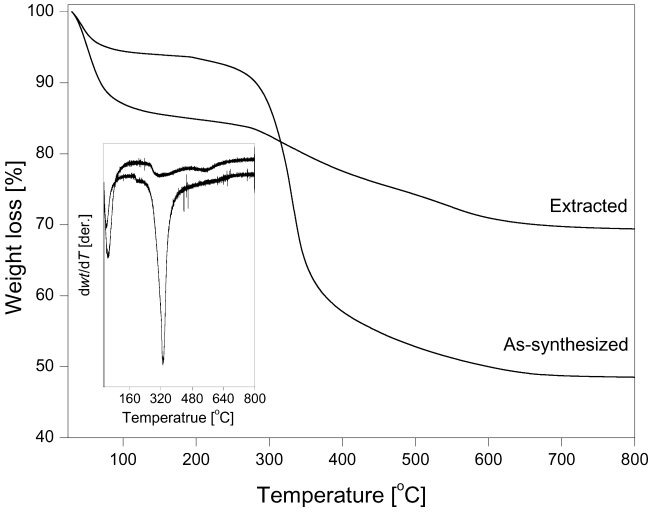

Figure 8. TG and DTG (inset) profiles of as-synthesized and solvent-extracted ZrPMO material prepared with Si/Zr = 10 by using this synthetic pathway.

**Plausible Mechanism**

Our results obtained by SAXS, $N_2$ sorption, XPS, TEM, and NMR spectroscopic techniques show that, even though no additional acid was added in the synthesis, highly ordered ZrPMO materials with a tunable zirconium content could be facilely prepared by using the $ZrOCl_2$/NaCl-assisted synthetic strategy by simply adjusting the amount of $ZrOCl_2$ in the synthesis gels. In practice, inorganic salts can play an important role in the synthesis of mesoporous materials especially for those nonionic surfactant-templating pathways, and recently a review article from Zhao et al. comprehensively detailed the effect of inorganic salts on the morphologies and structural properties of mesoporous silicates templated by nonionic surfactants.[35]

As far as the triblock copolymer-templating system (P123, F127, etc) is concerned, however, in most cases the inorganic additives are only nonhydrolyzable salts like sodium or potassium species, and the syntheses were still carried out under strongly acidic conditions.[7,44] In contrast, a combination of both "nonhydrolyzable" and "hydrolyzable" salts such as NaCl and $ZrOCl_2$ was used in this study under acid-free conditions. This synthetic pathway has never been reported for P123-templated PMOs, even though the NaCl/KCl-assisted acidic pathways have been frequently employed for the preparation of large-pore PMO materials.[7,37,45] It is well-established that both salts can respectively act as a well-understood micelle-promoting agent[35,44] (lower the critical micelle concentration and temperature of copolymer surfactant) and "catalyst"[39,50] for the hydrolysis and condensation of the silica precursors that were promoted by the self-generated acidity from the hydrolysis of inorganic $ZrOCl_2$. Indeed, the self-adjusted acidity, even though the zirconium salt amount (atomic ratio Si/Zr $\geq$ 10) added in the reaction gels is very small, is enough for the sol–gel processing of the bridged organosilanes due to their easier hydrolysis and condensation features in comparison with the conventional silica sources like tetraethoxysilane (TEOS) or tetramethoxysilane (TMOS).[51] Under such mild synthetic conditions, the induction time for precipitation is reasonably longer than that of the synthesis carried out under strongly acidic conditions, as described before, which might be responsible for the featureless morphologies of the final SBA-15-like ZrPMO products, even though their well-ordered framework channels could be easily assembled in this mild environment. As a matter of fact, this formation mechanism in nature is somewhat similar to the reported "acid–base pair" concept for those mesoporous nonsiliceous materials templated by copolymer surfactants, in which the appropriate acidity self-generated from the inorganic precursors is a key factor for the whole synthesis.[52,53] Likewise, in this work the organosilica precursor and $ZrOCl_2$ can be considered the so-called "base" and "acid", respectively. It is proposed that the hydrolyzed zirconyl cations may take the place of protons and adhere to either the hydrophilic side of the polymer micelle or the silanol group to form cationic species, which participate in the self-assembly process. Therefore, zirconium ions can be

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

effectively incorporated into the organosilicate frameworks due to the easiness of Zr–O–Si formation in this mild environment.[39,42] During this process, the presence of NaCl, a known micelle-promoting agent for copolymer P123, can change the ionic strength of the synthesis gels and favorably facilitate the formation of ordered ZrPMO materials, which has no direct interaction with the species involved in the self-assembly of the micelle and organosilica precursor.[39,46] Both salts have been found to be essential for the synthesis of highly ordered ZrPMO materials with large pore diameters.

## Conclusions

A new synthetic pathway was developed to incorporate zirconium ions into SBA-15-type PMO materials with excellent mesostructural ordering and tunable zirconium content by simply adjusting the $ZrOCl_2$ amount of the $ZrOCl_2$–NaCl salt combination, which was used as the promoting agent through the synthetic process and thus no additional mineral acids was necessary. A simple "neutralization" concept based on the chemical properties of the components of this synthesis system was discussed, in which the organosilica precursor and hydrolyzable $ZrOCl_2$ salt can be considered as the "base" and "acid", respectively. With this mechanism, the acidity self-generated by the zirconium salt is of great importance for the hydrolysis of the organosilica source. Simultaneously, the addition of NaCl can effectively enhance the interaction between the copolymer micelles and hydrolyzed species and facilitate the assembly of well-ordered ZrPMO materials. In comparison with those studies conducted under strongly acid conditions, this synthetic method is environmentally friendly and efficient in incorporating zirconium ions into the framework of the hybrid mesoporous materials. Actually, this synthetic pathway can also be applied to the preparation of other heteroatom-containing PMO materials, a series of Al-, Sn-, Fe-, and Cr-incorporated SBA-15-type mesostructures have been successfully prepared by using the corresponding inorganic chloride salts and will be reported in the near future.

## Experimental Section

**Chemicals:** All chemicals [zirconyl chloride octahydrate ($ZrOCl_2{\cdot}8H_2O, \geq 99\%$)] used as a zirconium source for the synthesis of zirconium-functionalized hybrid materials, triblock copolymer surfactant (Pluronic 123, molecular weight = 5800, $EO_{20}$-$PO_{70}EO_{20}$), and bis(trimethoxysilyl)ethane [$(CH_3O)_3SiCH_2CH_2Si(OCH_3)_3$, BTME, 96%] were purchased from Aldrich-Sigma Chemical Inc. All chemicals were used as received without further purification. Millipore water was used in all experiments.

**Synthesis of ZrPMO Materials:** Highly ordered ethylene-bridged ZrPMO materials can be successfully synthesized from BTME by using a $ZrOCl_2$–NaCl salt combination as the promoting agent for the assembly process, and there is no requirement for additional mineral acids. In a typical synthesis, P123 (1.5 g) and a predetermined amount of $ZrOCl_2{\cdot}8H_2O$ and NaCl were dissolved in deionized water (50 g) and stirred for 4 h at 40 °C. Then, BTME (1.96 mL) was added to the solution and stirred for 24 h at the same temperature, which was taken as the reaction temperature in the following text. The molar compositions of the synthesis are BTME/P123/$H_2O$/NaCl/$ZrOCl_2{\cdot}8H_2O$ = 1:0.034:400:0–8:0–0.4. The mother solution along with the precipitate was then transferred to an autoclave and hydrothermally treated for 48 h at 80 °C. The ZrPMO materials were finally obtained after filtration and two times extraction with HCl acidified ethanol (v/v, 3:100) at 60 °C for 6 h to remove the template.

**Characterization:** Small-angle X-ray scattering (SAXS) measurements were performed by using a synchrotron X-ray source of Pohang Accelerator Laboratory (PAL, Korea): Co-$K_\alpha$ ($\lambda$ = 1.608 Å) radiation with an energy range of 4–16 keV. Transmission electron microscopy (TEM) images were obtained with a JEOL2010 electron microscope with an acceleration voltage of 200 kV. Scanning electron microscopy (SEM) images were recorded with a JEOL 6400 microscope operating at 20 kV. Nitrogen adsorption isotherms were obtained with a Quantachrome's Quadrasorb SI analyzer at –196 °C. Before the measurements, the samples were degassed at 120 °C for 12 h in vacuo. The Brumauer–Emmett–Teller (BET) surface area was calculated by using experimental points at a relative pressure of $P/P_0$ = 0.05–0.25. The total pore volume was calculated by the $N_2$ amount adsorbed at the highest $P/P_0$ for each sample ($P/P_0$ = 0.99). The pore-size distribution was calculated by the conventional Barrett-Joyner-Halenda (BJH) method. The micropore area and volume were calculated by the *t*-plot method by using experimental points at a relative pressure of $P/P_0$ = 0.10–0.20. $^{13}C$ cross polarization (CP) and $^{29}Si$ MAS NMR spectra were obtained with a Bruker DSX400 spectrometer at room temperature with a 4 mm zirconia rotor spinning at 6 kHz (resonance frequencies of 79.5 and 100.6 MHz for $^{29}Si$ and $^{13}C$ CPMAS NMR, respectively; 90° pulse width of 5 μs, contact time 2 ms, recycle delay 3 s for both $^{29}Si$ and $^{13}C$ CP MAS NMR). Thermogravimetric analysis (TGA) was performed with a Perkin–Elmer Pyris Diamond TG instrument at a heating rate of 10 °C min$^{-1}$ in air. The zirconium content of the prepared ZrPMO materials was determined by ICP-Atomic Emission Spectroscopy (ICP-AES) by using a Plasma 400 (Perkin–Elmer) spectrometer equipped with Cetac6000AT+ ultrasonic nebulizer. To study the surface elements of the materials in their existing state, X-ray photoelectron spectroscopy (XPS) measurements were carried out with a PHI-1600ESCA System XPS spectrometer (Perkin–Elmer, USA) by using nonmonochromatic Mg-$K_\alpha$ radiation, operated at 15 kV and under $10^{-7}$ Pa pressure with photoelectron energy set at 1254 eV. The elements on the surface were quantified by using the peak areas.

**Supporting Information** (see footnote on the first page of this article): SEM images of the ZrPMO samples synthesized by using $ZrOCl_2$–NaCl with different Si/Zr molar ratios, SAXS patterns and SEM images of the samples synthesized.

# $H_5EPTPACH_2OH$: Synthesis, Relaxometric Characterization and $^1H$ NMR Spectroscopic Studies on the Solution Dynamics of Its $Ln^{III}$ Complexes

**Susana Torres,[a] José A. Martins,*[a] João P. André,*[a] Giovannia A. Pereira,[b] Robert Kiraly,[c] Ernö Brücher,[c] Lothar Helm,[d] Éva Tóth,[e] and Carlos F. G. C. Geraldes*[b]**

**Keywords:** Lanthanides / Contrast agents / MRI / Microscopic protonation scheme / Stability constants

The synthesis and characterization of a new metal chelator, 4-(*S*)-hydroxymethyl-3,6,10-tri(carboxymethyl)-3,6,10-triazadodecanedioic acid ($H_5EPTPACH_2OH$), is reported. Protonation constants for the ligand $H_5EPTPACH_2OH$ and for the previously reported $H_5EPTPAC16$ have been determined by potentiometry, which reveals that both ligands display slightly higher protonation constants relative to that of the ligand $DTPA^{5-}$. The stability constant for the $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ complex has also been determined by potentiometry. The obtained value ($\log K_{GdL} = 16.7$) is two orders of magnitude lower than that for the $[Gd(EPTPA)(H_2O)]^{2-}$ complex, which indicates the destabilizing effect of the pendant hydroxymethyl group at the EPTPA backbone. The microscopic protonation scheme has been deduced from the pH dependence of the $^1H$ NMR spectra of both $H_5EPTPACH_2OH$ and $H_5EPTPAC16$ ligands. The first two protonations occur exclusively at the backbone nitrogen atoms – the first protonation occurs preferentially at the more basic central nitrogen atom. The second proton distributes preferentially between the two terminal nitrogen atoms with the favoring of the trimethylene nitrogen atom over the ethylene nitrogen atom. The $Ln^{III}$ complexes of the ligand $H_5EPTPACH_2OH$ have been prepared and their solution dynamics studied by $^1H$ NMR spectroscopy. Two sets of resonances of very different intensities from two isomeric complexes have been observed. Relaxometric investigations ($^{17}O$ NMR and $^1H$ NMRD) demonstrate that the $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ complex displays an accelerated water-exchange rate ($k_{ex} = 87.6 \times 10^6\ s^{-1}$) that is close to the theoretically derived optimal value. However, the kinetic stability of this complex in phosphate-buffered solutions towards $Zn^{2+}$ transmetallation is quite low, but higher than that of the corresponding methyl derivative.

## Introduction

Magnetic resonance imaging (MRI) uses radiofrequency waves and a strong magnetic field to provide remarkably clear and detailed pictures of internal organs and tissues. The development of this imaging modality parallels the emergence of a new class of metallopharmaceutics, known as contrast agents (CAs).[1,2] Contrast agents are primarily $Gd^{III}$ complexes because this metal ion has seven unpaired electrons and a slow electronic relaxation rate.[3]

In fact, the image-enhancing capability of the commercially available poly(aminocarboxylate)-based chelates is only a few percent of the maximum value predicted by the Solomon–Bloembergen–Morgan theory.[4,5] In order to attain maximum relaxivities, the rotational correlation time ($\tau_r$), proton-exchange rate ($k_{ex}$), and electronic spin relaxation rates ($T_e$) have to be optimized simultaneously.[4,5]

The covalent attachment of $Gd^{III}$ chelates to slow-tumbling macromolecules (linear polymers,[6] carbohydrates,[7] proteins,[8] and dendrimers[9]) and the formation of host–guest noncovalent interactions between $Gd^{III}$ chelates and macromolecules[10] are successful strategies to increase $\tau_r$. An alternative way to achieve this goal is through self-assembly of amphiphilic $Gd^{III}$ chelates[11] or through the inclusion of lipophilic $Gd^{III}$ chelates in liposomes[12] or other lipid-based colloidal systems.[13]

In spite of the efforts to optimize the rotational correlation time of slow-tumbling $Gd^{III}$ complexes, the relaxivity

enhancement achieved may be limited if the water-exchange rate ($k_{ex}$) is not simultaneously optimized. When the water-exchange rate is too fast, the protons are not effectively relaxed. Conversely, the coordination site is needlessly occupied by a relaxed water molecule. Most $Gd^{III}$ complexes investigated to date as potential contrast agents have very slow water-exchange rates ($k_{ex} \approx 10^6\ s^{-1}$), far from its optimal value (about $k_{ex} = 10^8\ s^{-1}$).

The water exchange in $Gd^{III}$ complexes is essentially determined by two factors, both of which can, to some extent, be controlled by design.[14] The first and most easily controlled factor is the electron density on the central lanthanide ion. Electron deficiency on the metal ion results in slow dissociation of the bound water molecule as a result of the enhanced electrostatic attraction responsible for the shortening of the lanthanide–water bond. Therefore, ligands containing anionic groups (e.g. carboxylates) are responsible for a fast water exchange, whereas neutral ligands (e.g. amides or alcohols) would favor slower water exchange. Another way of obtaining $Gd^{III}$ complexes with fast water exchange rates is related to the design of ligands that display an increased steric hindrance around the water coordination site. Muller and co-workers have reported a reduction in the time of residence of the bound water molecule ($\tau_M$; $\tau_M = 1/k_{ex}$) for a series of $Gd^{III}$–DTPA complexes bearing diverse substituents on the C4 carbon atom of the ethylene bridge: Gd(*S*)-C4-Me-DTPA ($\tau_M^{310}$ = 91 ns), Gd(*S*)-C4-*n*Bu-DTPA ($\tau_M^{310}$ = 82 ns), Gd(*S*)-C4-*i*Bu-DTPA ($\tau_M^{310}$ = 108 ns), Gd(*S*)-C4-*i*Pr-DTPA ($\tau_M^{310}$ = 98 ns), and Gd-C4-diMe-DTPA ($\tau_M^{310}$ = 57 ns) relative to that of the parent $Gd^{III}$–DTPA complex ($\tau_M^{310}$ = 143 ns).[15] The same effect has been reported by the same authors for $Gd^{III}$–DTPA complexes bearing ethoxybenzyl,[16] benzyl,[17] and (4,4-diphenylcyclohexyl)phosphonooxymethyl[18] substituents on the C4 carbon atom of the ethylene bridge. A comparative study of the four possible regioisommerically benzyl-functionalized $Gd^{III}$–DTPA complexes showed that substitution at C4 (next to the ethylene bridge terminal nitrogen atom) and C7 (central acetate) yields higher steric hindrance of the coordinated water molecule (with a corresponding higher increase in the water-exchange rate) than substitution at C5 (next to the ethylene bridge central nitrogen atom) and C2 (terminal acetate).[19] However, substitution at C5 and C4 are the most effective in sterically reducing the accessibility of $Zn^{2+}$ to the ligand, and thus are the most protective against transmetallation by this ion.[19]

Merbach et al. also demonstrated that the insertion of an extra methylene group to the backbone or to a pendant arm in macrocyclic tetraacetate complexes and to DTPA-derived complexes causes steric compression around the water-binding site, with a corresponding increase in the bound-water-exchange rate ($k_{ex}$) by a factor of one or two orders of magnitude for $[Gd(DTTA\text{-}prop)(H_2O)]^{2-}$ and $[Gd(EPTPA\text{-}bz\text{-}NO_2)(H_2O)]^{2-}$, respectively.[20] In solution, lanthanide(III) complexes of $H_4DOTA$-like ligands are typically present as a mixture of two diastereoisomers: the square antiprismatic (SAP) or M ("major") and the twisted square-antiprismatic (TSAP) or m ("minor") isomer.[21] Studies revealed that these isomers display different $\tau_M$ values.[22] The neighborhood of the water molecule in a TSAP isomer is more sterically crowded, and therefore the water molecule exchanges 10–100 times faster than in a SAP isomer. Therefore, $Gd^{III}$ complexes displaying, in solution, exclusively the TSAP isomer could potentially lead to high relaxivity CAs.

In this paper, we report the synthesis and characterization of the ligand 4-(*S*)-hydroxymethyl-3,6,10-tris(carboxymethyl)-3,6,10-triazadodecanedioic acid (**1**, $H_5EPTPA\text{-}CH_2OH$) and of its $Ln^{III}$ complexes and compare the properties of this ligand with that of its hexadecanoyl ester derivative (**2**, $H_5EPTPAC16$)[23] [Figure 1]. The protonation constants were determined for both ligands by potentiometry, and their microscopic protonation scheme was obtained with NMR pH titrations. For ligand **1**, the stability constant of the $Gd^{III}$ complex was also obtained by potentiometry, and the solution dynamics of several $Ln^{III}$ complexes was studied by $^1H$ NMR spectroscopy. $^{17}O$ NMR and NMRD measurements have been performed on the $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ complex, thus allowing us to determine the parameters that govern its relaxivity. Its stability towards $Zn^{2+}$ transmetallation was also tested.

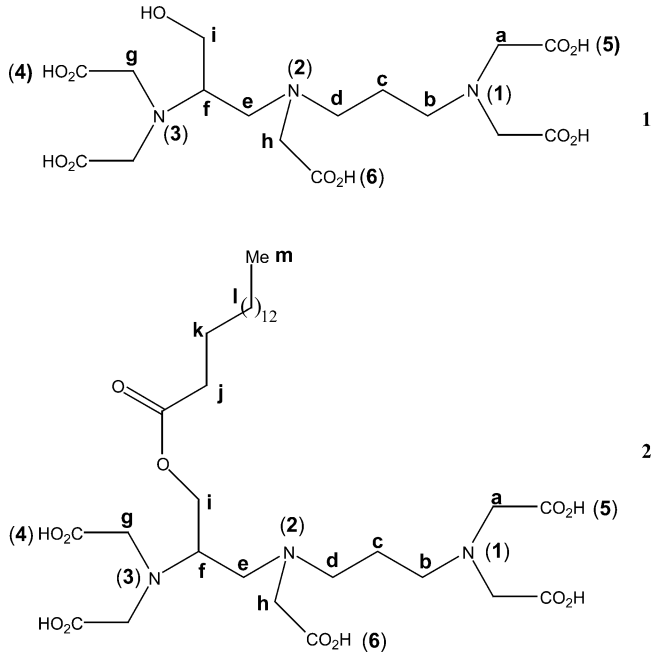

Figure 1. Chemical structures of the ligands $H_5EPTPACH_2OH$ (**1**) and $H_5EPTPAC16$ (**2**). Arbitrary numbers and labelling is shown for convenience of the $^1H$ NMR assignment.

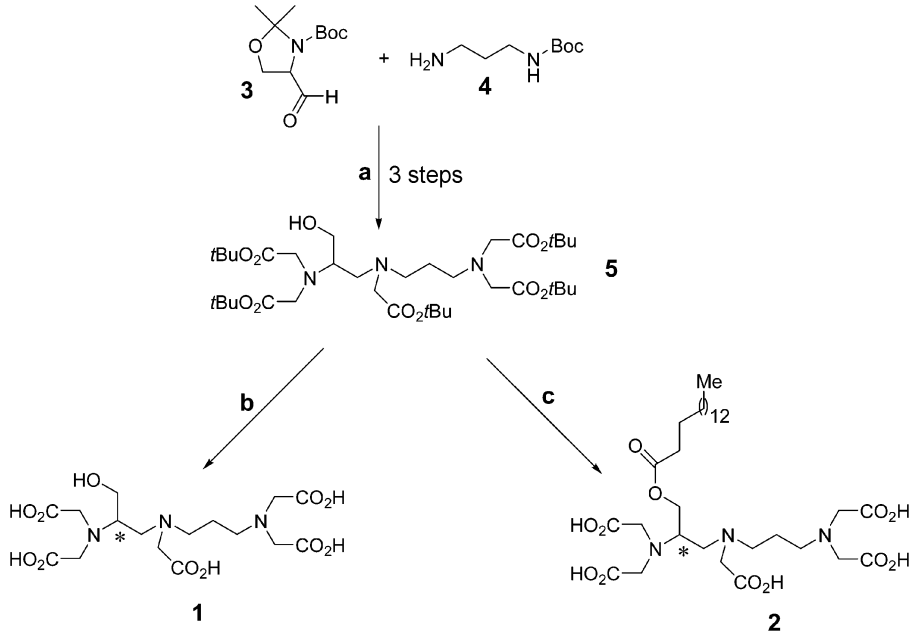
## Results and Discussion

### Synthesis of the Ligands

We have recently reported a new synthetic path to metal chelators based on the EPTPA skeleton bearing a hydroxymethyl group on the ethylenediamine unit. The substi-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 



Scheme 1. (a) ref.[22] (b) 6M HCl/EtOH (1:1). (c) ref.[23]

tution of an ethylene by a propylene bridge on the DTPA skeleton is aimed at imposing steric compression around the water binding site, and therefore, to lead to $Gd^{III}$ complexes with fast water-exchange rates. The hydroxymethyl "handle" is ideal for conjugation of the key protected intermediate **5** (Scheme 1) to organic moieties for targeting and/or $\tau_r$ optimization purposes. As *proof of concept* we have recently reported the synthesis and characterization the new micellar contrast agent $[Gd(EPTPAC16)(H_2O)]^{2-}$.[23]

Acidic deprotection of the fully protected intermediate **5** affords in quantitative yields the new chelator $H_5$EPTPA-$CH_2OH$ (**1**) [Scheme 1]. The synthesis started with the unnatural *R* enantiomer of serine (D-Serine), and it is reasonable to assume that the synthetic route devised is not likely to have led to racemization or inversion of configuration on the stereogenic center. Ligand **1** displays a stereogenic center that is assumed to have an absolute *S* configuration. The apparent inversion of configuration *R*→*S* reflects only a change in the assignment of priority of one of the groups attached to the stereogenic center. The enantiomer excess could have been determined for the fully protected intermediate **5** through, for example, the MTPA ester method.[24] Although the enantiomeric excess was not measured, the obtained $[\alpha]_D$ values of –31.9 ($c$ = 1.0, $H_2O$, pH = 1.40) and –6.3 ($c$ = 1.0, $H_2O$, pH = 9.8) confirm that the fully deprotected compound **1** is optically active. The dramatic difference in the measured $[\alpha]_D$ values under acidic and basic conditions probably reflects the rigidity of the ligand in acidic media, which results from intramolecular hydrogen bonding.

## Potentiometric Determination of Protonation and Stability Constants

The protonation constants of the ligands EPTPA-$CH_2OH^{5-}$ and $EPTPAC16^{5-}$ were determined by pH potentiometric titrations (Figure 2). The protonation constants of the two ligands, $pK_i = \log K_i^H$, where $K_i^H$ is defined as in Equation (1), are listed and compared to those of similar ligands and DTPA in Table 1 (standard deviations are shown in parenthesis).

$$K_i^H = [H_iL]/[H_{i-1}L][H^+];\ i = 0,1,2,3,4,5 \quad (1)$$

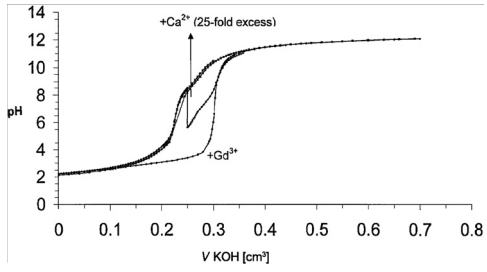


Figure 2. Potentiometric pH titration curves for the ligand EPTPA-$CH_2OH^{5-}$ in the absence and in the presence of $Ca^{II}$ or $Gd^{III}$ [$c$(EPTPACH$_2$OH) = 2.055 mM, $c$(KOH) = 0.2461 M, metal/ligand ratio = 1:1, $I$ = 1.0 M KCl, $T$ = 25 °C].

Both $EPTPACH_2OH^{5-}$ and $EPTPAC16^{5-}$ ligands display a slightly higher protonation constant for the first protonation step than that for the ligand $DTPA^{5-}$[25], as observed previously for the unsubstituted ligand $EPTPA^{5-}$[26] and the backbone substituted EPTPA-bz-$NO_2^{5-}$[20c] (see Table 1). Such an increase in the protonation constants relative to those for $DTPA^{5-}$ also occurs for the subsequent protonation steps for all the backbone substituted ligands, including the two studied in this work. This general increase in the protonation constants upon replacement of one ethylene group in the backbone of $DTPA^{5-}$ by one trimethylene group results from reduced electrostatic repulsion between the protonated amino groups on lengthening of the chain between them.[26] The most pronounced increase is ob-

Table 1. Protonation constants for the ligands $H_5EPTPACH_2OH$ (**1**) (25 °C, $I$ = 1.0 M KCl) and $H_5EPTPAC16$ (**2**) (25 ± 0.2 °C, $I$ = 0.1 M) and stability constants for the $Gd^{III}$–$EPTPACH_2OH$ complex (25 °C, $I$ = 1.0 M KCl). Data for other ligands are included for comparison.

| | $H_5DTPA$[25] | $H_5EPTPA$-bz-$NO_2$[20c] | $H_5EPTPA$[26] | $H_5EPTPACH_2OH$[a] | $H_5EPTPAC16$[a] |
|---|---|---|---|---|---|
| p$K_1$ | 10.41 | 10.86(±0.01) | 10.60 | 10.65(±0.08) | 11.04(±0.01) |
| p$K_2$ | 8.37 | 8.91(±0.02) | 8.92 | 8.39(±0.09) | 8.91(±0.02) |
| p$K_3$ | 4.09 | 4.70(±0.02) | 5.12 | 4.43(±0.09) | 5.41(±0.03) |
| p$K_4$ | 2.51 | 3.25(±0.02) | 2.80 | 2.78(±0.10) | 5.02(±0.02) |
| p$K_5$ | 2.04 | 2.51(±0.03) | [c] | 2.75(±0.08) | 2.66(±0.08) |
| log $K_{GdL}$ | 22.50 | 19.20 (±0.02) | 22.77[b] | 16.7(±0.05) | [c] |
| log $K_{GdHL}$ | 1.80 | 3.40(±0.02) | [c] | 3.64(±0.04) | [c] |

[a] This work. [b] In ref.[20c] the corrected values for $[Gd(EPTPA)(H_2O)]^{2-}$ were found: log $K_{GdL}$ = 18.75(±0.07) by direct titration and log $K_{GdL}$ = 17.5 (±0.3) by competition with EDTA. [c] Not determined.

served for the third and fourth protonation steps for the ligand $EPTPAC16^{5-}$. This agrees with the fact that polyamines with increasing chain length usually display increasing protonation constants.[27]

The first protonation constant for the ligands $EPTPA^{5-}$ and $EPTPACH_2OH^{5-}$ is practically the same (within experimental error). The protonation constants for the other protonation steps are slightly lower for $EPTPACH_2OH^{5-}$ than those observed for $EPTPA^{5-}$. The first four protonation constants of the ligand $EPTPAC16^{5-}$ are higher than those of the nonconjugated ligand $EPTPACH_2OH^{5-}$. A rather pronounced effect is observed for the fourth protonation constant of $EPTPAC16^{5-}$ – its value is two orders of magnitude higher than the corresponding value for $EPTPA\text{-}CH_2OH^{5-}$.

The stability and the protonation constants of the metal complexes are expressed in Equation (2) and Equation (3).

$$K_{ML} = [ML]/[M][L] \quad (2)$$

$$K_{MH_iL} = [MH_iL]/[MH_{i-1}L][H^+];\ i = 1,2 \quad (3)$$

These thermodynamic stability constants, obtained by pH potentiometry for the $Gd^{III}$–$EPTPACH_2OH$ system (Figure 2), are also listed in Table 1 and compared to those for the Gd complexes of similar ligands and DTPA. The species distribution diagram for the system $Gd^{III}/EPTPA\text{-}CH_2OH/(H^+)$, represented in Figure 3, indicates that above pH 5, there is no free $Gd^{III}$ in a solution containing a 1:1 molar ratio of $Gd^{III}$ and ligand. The unprotonated complex $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ is the only species present at physiological pH 7.4. For the ligand $EPTPAC16^{5-}$, the observation of precipitation in the system for pH values below 4 precluded the determination of the stability constants of its $Gd^{III}$ complex.

The value previously determined for the complex $[Gd(EPTPA)(H_2O)]^{2-}$ (log $K_{GdL}$ = 22.77) from a competition study with $EDTA^{4-}$[26] is about the same as that measured for $[Gd(DTPA)(H_2O)]^{2-}$. This value did not seem reasonable because of the fact that EPTPA complexes form one six-membered chelates, which are less stable than the five-membered rings observed for the DTPA analogues. We therefore would have expected a lower stability for the EPTPA complexes. This was indeed demonstrated by Merbach et al.,[20c] who found, for $[Gd(EPTPA)(H_2O)]^{2-}$, a

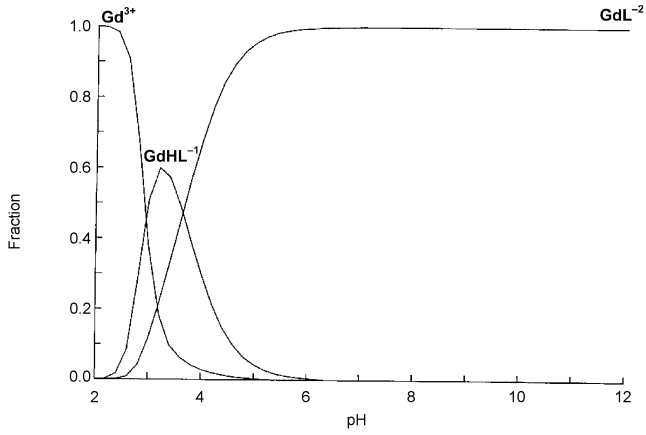

Figure 3. Species distribution curves for a 2 mM $Gd^{III}/EPTPA\text{-}CH_2OH/(H^+)$ system containing a 1:1 molar ratio of $Gd^{III}$ to ligand ($I$ = 1.0 M KCl, $T$ = 25 °C). Fraction is relative to 2 mM total $Gd^{III}$ species.

value log $K_{GdL}$ = 18.75(±0.07) by direct titration and log $K_{GdL}$ = 17.5(±0.3) by competition with EDTA. The value log $K_{GdL}$ = 16.7 ± 0.05 obtained in the present study for the thermodynamic stability constant of the complex $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ is two orders of magnitude lower than the corrected value for $[Gd(EPTPA)(H_2O)]^{2-}$ and even lower than the value for the complex $[Gd(EPTPA\text{-}bz\text{-}NO_2)(H_2O)]^{2-}$,[20c] which indicates the destabilizing effect of the $CH_2OH$ substituent group at the EPTPA backbone. All these substitutions occur at the C4 position (position b, see Figure 1) of the EPTPA backbone, which might not be optimal for the stability of the complex; however, this depends on the type of substituent. It has been shown that substitution at the EPTPA backbone with a phenyl group has a stabilizing effect on the $[Gd(EPTPA)(H_2O)]^{2-}$ structure towards $Zn^{2+}$ transmetallation; the effect is much higher when the substitution is at C9 than at C4 (positions b and f, respectively, see Figure 1), but substitution with a methyl group at C9 or C4 has no stabilizing effect on the parent compound.[28]

The present results, summarized in Table 1, show that the stability of the $Ln^{III}$ complexes of the EPTPA derivatives decreases when the sum of the protonation constants of the free ligand increases, which is the opposite of the usual

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

trend found for many polyamino–polycarboxylic acids.[29] The trend can be explained by the presence of an extra $CH_2$ group in the ligand backbone, which increases the basicity of the adjacent nitrogen donor atoms, but reduces the stability of the six-membered chelate ring formed.

## NMR pH Titrations

The macroscopic protonation constants obtained by potentiometry give no information on the microscopic sequence of protonation of the ligand sites. This protonation sequence can be obtained by $^1H$ NMR pH titration, where the chemical shifts of the ligand methylene protons are determined as a function of the pH, since the protonation of a basic site of a poly(aminocarboxylate) ligand results in a deshielding of the adjacent nonlabile methylene protons.[30] Changes in chemical shifts can quantitatively indicate the site of protonation.[30,31]

The $^1H$ NMR pH titration curves for some of the protons of the ligands $H_5EPTPACH_2OH$ and $H_5EPTPAC16$ are shown in Figure 4. The corresponding resonances were assigned at different pH values on the basis of signal multiplicities, the signal crossovers, and COSY spectra in the whole pH range studied. These titration curves display sharp changes at different pH values, which relate to the protonation states of the ligand. Since there is fast exchange on the NMR time scale among the various protonated species ($H_nL$), the observed shift of a given proton is given by the average of the shifts of the various species ($\delta_{H_nL}$) weighted by their molar fractions ($x_n$); $\delta_{obs} = \Sigma x_n \cdot \delta_{H_nL}$.[30] The procedure used to obtain the protonation fractions at each ligand site has been described in detail.[31] In summary, the shifts of the protonated species ($\delta_{H_nL}$), obtained by fitting the experimental pH titration curves by using the potentiometric protonation constants, were used to calculate the protonation fractions (%) at the nitrogen [$f_N = f_{(1)}$, $f_{(2)}$, $f_{(3)}$] and oxygen [$f_O = f_{(4)}$, $f_{(5)}$, $f_{(6)}$] atoms (labelled in Figure 1) of each ligand protonation state $H_nL$ (integer $n$ = 1, 2, 3,... is the number of moles of acid added per mole of ligand). It was assumed that the protonation shifts at the various sites are additive, with a total shift ($\Delta\delta$) given by the expression $\Delta\delta = \Sigma C_N \cdot f_N + \Sigma C_{N'} \cdot f_N + \Sigma C_O \cdot f_O$, where $C_N$ = 0.75 ppm, $C_{N'}$ = 0.35 ppm and $C_O$ = 0.20 ppm are pH-independent shielding constants valid for linear poly(aminocarboxylate) ligands.[30]

The values of $f_N$ [$f_{(1)}$, $f_{(2)}$, $f_{(3)}$] and $f_O$ [$f_{(4)}$, $f_{(5)}$, $f_{(6)}$] were calculated for the $H_nL$ species of the two ligands and compared with those reported for $H_5EPTPA$[26] (see Table S3 in the Supporting Information). The first two protonations occur in all cases exclusively at the backbone nitrogen atoms [$f_O = f_{(4)}$, $f_{(5)}$, $f_{(6)} = 0$]. The $f_i$ values for $n$ = 1 show that the first protonation is very similar for the three ligands, where the more basic central nitrogen atom [$N_{(2)}$] is protonated preferentially to the terminal ones, as was also found for DTPA.[26,30,31] For $n$ = 2, there is a preference for the protonation of the terminal nitrogen atoms over that of the central nitrogen atom in all ligands. However, the protonation of the two terminal nitrogen atoms is quite distinct in the three asymmetric ligands EPTPA and the two derivatives studied in this work. The protonation of the trimethylene nitrogen atom [$N_{(1)}$] is favored over that of the ethylene nitrogen atom [$N_{(3)}$] for $n$ = 1–3, because of the increased separation in the positive charges in $N_{(1)}$–$N_{(2)}$ relative to $N_{(2)}$–$N_{(3)}$ and possibly also because of the stabilization of a six-membered ring by hydrogen bonding between $N_{(1)}$ and $N_{(2)}$. The protonation of $N_{(3)}$ is less favored in the two EPTPA derivatives than in EPTPA because of the steric effect of the C4-substituents in the ethylenediamine moiety. The forms with the protonated terminal nitrogen atoms are stabilized by internal hydrogen bonding with the corresponding carboxylate groups, which leads to increased values for the second and third protonation constants relative to those for DTPA.[26,30,31] These internal hydrogen bonds also lead to preferential protonation of the carboxylate groups bound to the less protonated nitrogen atoms, as shown by the $f_i$ values, which could be obtained for $n > 2$.

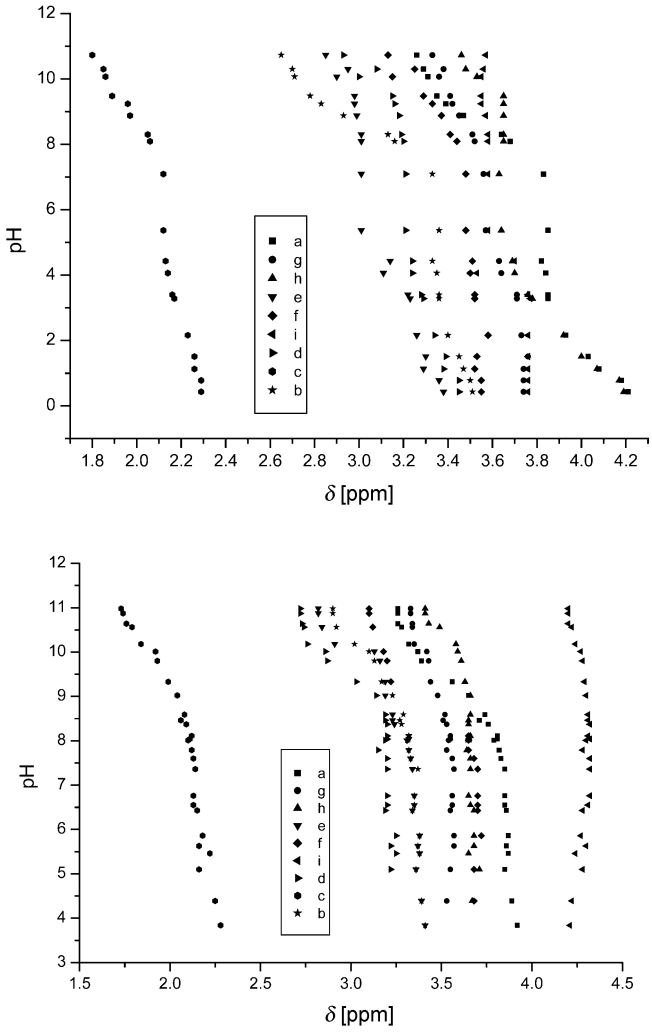

Figure 4. Variation of the $^1H$ NMR chemical shifts versus pH for the ligands $H_5EPTPACH_2OH$ (top) and $H_5EPTPAC16$ (bottom) [see Figure 1 for the labelling of protons].

### $^1$H NMR Study of [Ln(EPTPACH$_2$OH)]$^{2-}$ Complexes

The $^1$H NMR spectra of the [Ln(EPTPACH$_2$OH)]$^{2-}$ complexes, both diamagnetic (Ln = La, Lu, Y) and paramagnetic (Ln = Pr, Nd, Sm, Eu, Tb, Dy, Yb), were obtained in $D_2O$ at pH 7.0 as a function of temperature (7, 25, 60 and 80 °C; see Figure S1 in the Supporting Information for some typical spectra). The diamagnetic spectra (illustrated in Figure S1a by the $Y^{III}$ complex) are quite crowded and were not fully assigned. The presence of high and low intensity resonances could be seen throughout the whole spectrum for all the diamagnetic complexes. The COSY spectrum of [Y(EPTPACH$_2$OH)]$^{2-}$ (Figure S2a, Supporting Information) contains two sets of five cross peaks of high and low intensity, which correspond to the five AB quartets characteristic of the methylene protons of the five bound acetate groups of EPTPA in two isomeric complexes of high and low populations. The signals for the $Lu^{III}$ and $Y^{III}$ complexes did not broaden significantly at high temperatures. This is not the case for the $La^{III}$ complex, whose signals becomes very broad at high temperature, as found for the $La^{III}$- and $Lu^{III}$–DTPA complexes, in which the central nitrogen racemization process is quite effective, and therefore, the spectra of the two asymmetric conformers present is effectively averaged.[32,33]

All the $^1$H NMR spectra of the paramagnetic complexes studied also show high and low intensity resonances. This is best seen in the sharper spectra of the early-$Ln^{III}$ series (see Figure S1b,c,d), which confirms the presence of two isomeric complexes, one of much higher population than the other. The major complex, whose spectrum exhibits 21 resonances of high intensity, has a smaller spread of proton paramagnetic shifts than that of the low intensity resonances of the minor complex. The presence of one resonance per nonexchangeable ligand proton shows that racemization of the central nitrogen through the wagging of the attached acetate group does not occur. Again, a different result is observed for the spectra of the paramagnetic $Ln^{III}$–DTPA complexes, where racemization of the central nitrogen through a wagging motion of its bound acetate group averages the spectra of the two asymmetric conformers present in solution.[34,35]

All the paramagnetic spectra were too complex to be assigned, even with the help of observable COSY cross peaks (Figure S2b,c). The signals from the major isomer were not significantly broadened at high temperatures, in contrast to those from the minor isomer. This is most clearly observed for the spectrum of the $Sm^{III}$ complex (Figure S1c), with a major/minor ratio of 25:4, in which the broadening of the three high-frequency doublets (7.66, 7.27, and 6.85 ppm) at 40 °C makes the couplings unobservable. Further, of the three low-frequency multiplets, the one at –2.02 ppm is selectively broadened at 40 °C. The major and minor isomers observed in the [Ln(EPTPACH$_2$OH)]$^{2-}$ complexes result from the conformational properties of the ligand backbone. While the six-membered ring formed by the $Ln^{III}$–propylenediamine chelate is locked in a chair conformation,[36] the ethylenediamine moiety can adopt a δ or λ conformation in its five-membered ring chelate. One of these conformations places the $CH_2OH$ substituent in a more stable, less-crowded position than that in the other conformation. The $CH_2OH$ substituent prevents the central acetate wagging motion and also slows down the δ/λ backbone interconversion process that averages the spectra of the major (M) and minor (m) complexes. The selective broadening of the signals of minor complex that results from this dynamic process is a consequence of the equilibrium constant $K_{eq}$ = [m]/[M] << 1 being unfavorable to the m species, which leads to relative kinetic constants $k$(m→M) >> $k$(M→m).

### $^{17}$O NMR, $^1$H NMRD and EPR Measurements

The water-exchange rate was determined for the $Gd^{III}$–EPTPACH$_2$OH$^{5-}$ complex from a variable-temperature $^{17}$O NMR spectroscopic study. Additionally, the magnetic field dependence of the longitudinal water proton relaxivities ($r_1$) [nuclear magnetic relaxation dispersion − NMRD − curves] at different temperatures and EPR spectra were measured on the same complex with the objective of determining the parameters that describe water exchange, rotation, electronic relaxation, and proton relaxivity.

The obtained experimental NMRD data (Figure 5) and the $^{17}$O NMR chemical shifts ($\Delta\omega_r$), longitudinal ($1/T_{1r}$) and transverse ($1/T_{2r}$) relaxation rates (Figure 6) were analyzed simultaneously by using the Solomon–Bloembergen–Morgan (SBM) theory (for the equations used in the data analysis, see the Supporting Information). It was assumed that [Gd(EPTPACH$_2$OH)(H$_2$O)]$^{2-}$ had one inner-sphere water molecule ($q$ = 1), as in the [Gd(EPTPA)(H$_2$O)]$^{2-}$ and [Gd(EPTPA-bz-NO$_2$)(H$_2$O)]$^{2-}$ complexes.[20c] The parameters obtained in the fit are shown in Table 2, and Figures 5 and 6 show the corresponding fitted curves obtained for the NMRD and $^{17}$O NMR spectroscopic data. The ratio of the rotational correlation times of the Gd–O and Gd–H vectors, $\tau_{rO}$ and $\tau_{rH}$, respectively, fluctuated during the fits around its theoretical lower limit of 0.65 (based on geometrical considerations) and has been fixed to that value.[37] Some parameters given in Table 2 have been adjusted in preliminary fits and fixed in the final fitting procedure. Other parameters were fixed in the fit to typical values from the literature:[4,5] the $^{17}$O scalar coupling constant $A/\hbar$ = $-3.2 \times 10^6$ rad s$^{-1}$, the relative diffusion coefficient between the complex and water molecules $D_{GdH}^{298} = 25 \times 10^{10}$ m$^2$ s$^{-1}$ and the corresponding activation energy $E_{DGdH}$ = 25 kJ mol$^{-1}$, the distance of closest approach between the $Gd^{III}$ ion and the outer-sphere water molecules $a_{GdH}$ = 3.6 Å, the distances between $Gd^{III}$ and the coordinated water oxygen atom $r_{GdO}$ = 2.50 Å and protons $r_{GdH}$ = 3.10 Å, the quadrupolar coupling constant for the bound water $^{17}$O $\chi(1+\eta^2/3)^{1/2}$ = 7.68 MHz,[38] and the empirical constant for the outer-sphere contribution to the $^{17}$O chemical shift $C_{os}$ = 0.1.[20c] The values obtained for the activation parameters for water exchange, $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$, and for the activation energies, $E_v$ and $E_R$, are very close to those obtained for the [Gd(EPTPA)(H$_2$O)]$^{2-}$ and [Gd(EPTPA-bz-NO$_2$)(H$_2$O)]$^{2-}$ complexes (Table 2).[20c]

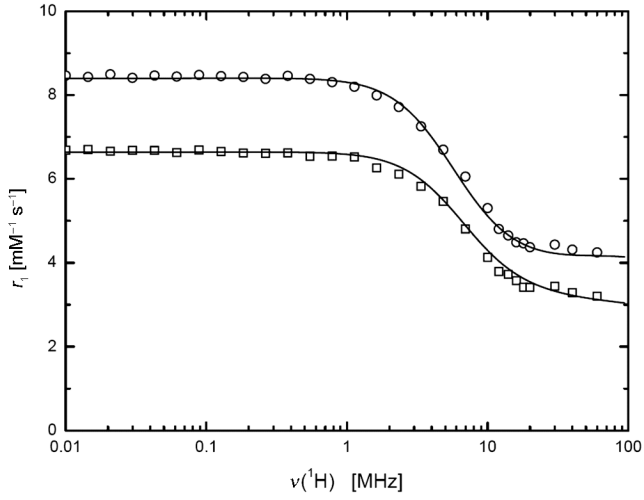

Figure 5. $^1$H NMRD profiles at 25 °C (circles) and 37 °C (squares) for $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$. The lines represent curves from results of a simultaneous fit of NMRD and $^{17}$O NMR spectroscopic data.

Table 3 compares the values for the parameters that determine relaxivity – the water-exchange rate ($k_{ex}^{298}$), the rotational correlation time of the complex ($\tau_{rO}^{298}$) and the electron spin relaxation parameters ($\Delta^2$ and $\tau_V^{298}$) – obtained for $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ with the corresponding values for $Gd^{III}$ complexes with other ligands containing the EPTPA structure and with DTPA.[20c,23,39] The 20 MHz proton relaxivities obtained for those systems are also compared.[26] The water-exchange rate of $[Gd(EPTPA\text{-}CH_2OH)(H_2O)]^{2-}$, $k_{ex}^{298} = 87.6 \times 10^6$ s$^{-1}$, is consistent with values obtained for analogous chelates that form between $Gd^{III}$ and EPTPA-based ligands and is close to the theoretically derived optimal value ($k_{ex}^{298} \approx 10^8$ s$^{-1}$[20c]). In all these compounds, steric compression around the water binding site leads to accelerated water exchange relative to DTPA-based $Gd^{III}$ complexes.[20c,23] However, it is interesting to observe that, while the inclusion of substituents on the C4 carbon atom of the ethylene bridge of a series of $Gd^{III}$–DTPA complexes leads to a 3–5 fold increase in $k_{ex}^{298}$ relative to that of the parent complex $[Gd(DTPA)(H_2O)]^{2-}$,[15–18] similar substitution on the C4 carbon atom of the ethylene bridge of a series of $Gd^{III}$–EPTPA complexes leads to a 2–4 fold decrease in $k_{ex}^{298}$ relative to that of the parent complex $[Gd(EPTPA)(H_2O)]^{2-}$;[20c,23] $[Gd(EPTPA)(H_2O)]^{2-}$ has a $k_{ex}^{298}$ value that is 100 times larger than that of $[Gd(DTPA)(H_2O)]^{2-}$. Another study has also shown that substitution by a methyl group at C4, and specially at C9 (propylene bridge), in the parent complex gives the highest $k_{ex}$ values, but substitution by a bulkier phenyl group at both positions decreases the water-exchange rates to values only 3 times larger than that for $Gd^{III}$–DTPA.[28]

With regard to rotational dynamics, the rotational correlation time obtained for $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ is comparable to the values for other small $Gd^{III}$ complexes, where the relative values increase, as expected, with their molecular weights. Therefore, the 20 MHz proton relaxivity

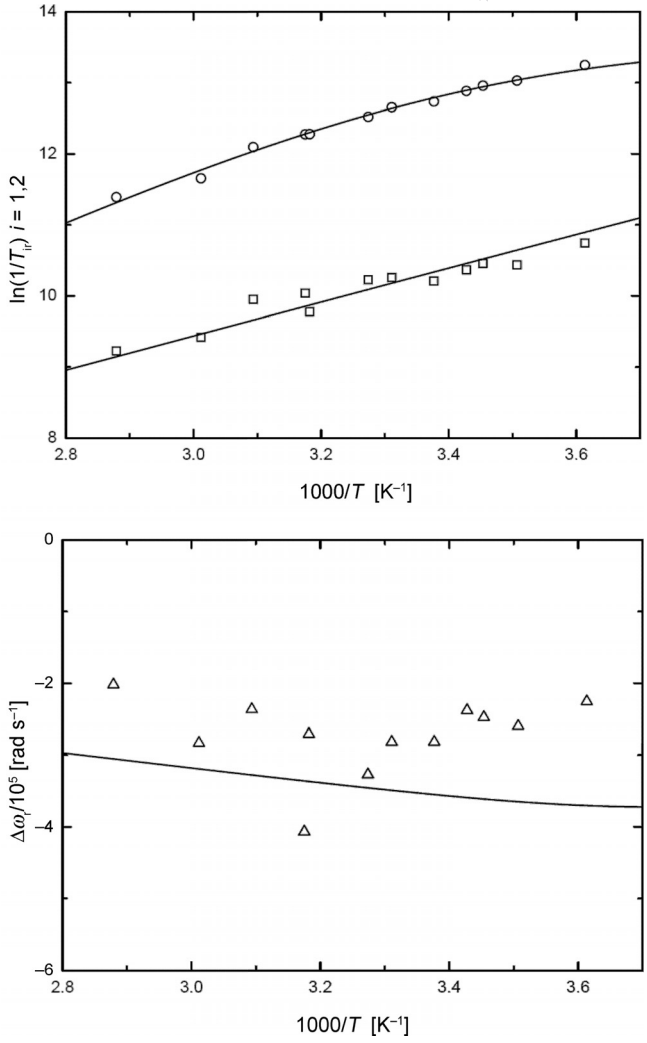

Figure 6. Temperature dependence of transverse and longitudinal $^{17}$O relaxation rates (top) and $^{17}$O chemical shifts (bottom) for $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ at $B$ = 4.7 T. The lines represent curves from results of a simultaneous fit of NMRD and $^{17}$O NMR spectroscopic data.

Table 2. Parameters obtained for the $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ chelate from the analysis of $^{17}$O NMR and NMRD data (parameters in italics have been fixed in the final fit).

| Parameter | |
|---|---|
| $k_{ex}^{298}$ [$10^6$ s$^{-1}$] | 87.6 ± 16.3 |

[a] This work. [b] Monomer form. [c] At 37.0 ± 0.1 °C and pH = 7.6 ± 0.1. [d] At 37.0 ± 0.1 °C and pH = 7.5 ± 0.1.

In our combined analysis of the $^{17}O$ NMR and NMRD data, we used the simple Solomon–Bloembergen–Morgan (SBM) theory, which is known to give only a rough approximation for electron spin relaxation rates $1/T_{1e}$ and $1/T_{2e}$.[40–42] We will therefore not discuss the parameters linked to it ($\tau_v$, $\Delta^2$). X-band EPR spectra of the $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ complex in aqueous solution at 298 K gave an approximately Lorentzian line centered at a magnetic field corresponding to $g_L \approx 2.0$, with an experimental peak-to-peak linewidth $\Delta H_{pp}$ = 23.64 ± 0.05 mT. The value for the linewidth was independent of the concentration of the complex in the range studied. The corresponding transverse electronic relaxation rate ($1/T_{2e}$) was calculated using Equation (4), in which the symbols have their usual meaning.[43]

$$\frac{1}{T_{2e}} = \frac{g_L \mu_B \pi \sqrt{3}}{h} \Delta H_{pp} \quad (4)$$

The calculated transverse electron spin relaxation rate of $(1/T_{2e})_{exp} = 2.265 \times 10^{10}$ $s^{-1}$ (at $B$ = 0.34 T) is about three times larger than $(1/T_{2e})_{calc} = 7.14 \times 10^9$ $s^{-1}$, the value calculated by using Morgan's equation (A20, Supporting Information) with $\Delta^2$ and $\tau_V^{298}$ obtained from the simultaneous fitting of the $^{17}O$ NMR and $^1H$ NMRD data (Table 3). X-band experimental EPR values of $1/T_{2e}$ have been systematically found to be larger than those calculated for many $Gd^{III}$ complexes, which confirms the deficiencies of SBM theory.[31,43,44,45] The use of a more recent description of electron spin relaxation needs, however, EPR measurements to be made over a wide temperature range and with different frequencies.[46]

### Transmetallation Kinetics

The kinetic stability of $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ in solution towards transmetallation with $Zn^{2+}$ was evaluated by the time dependence of the decrease in the water proton longitudinal relaxation rate ($R_1^p$) of phosphate-buffered solutions containing $Zn^{2+}$.[47] Precipitation as phosphates of the $Gd^{3+}$ ions released as a result of substitution by $Zn^{2+}$ leads to a decrease in $R_1^p$ that is proportional to the amount of released $Gd^{3+}$ ions. In the absence of $Zn^{2+}$, the stability of the $Gd^{3+}$ complex in the phosphate buffer depends on the buffer concentration, and is much higher at 10 mM than at 67 mM (Figure 7). The kinetic stability in the concentrated buffer is similar to the behavior observed for $[Gd(4\text{-Me-EPTPA})(H_2O)]^{2-}$.[28] In the presence of $Zn^{2+}$, the decrease in $R_1^p$ is much faster, which indicates a fast and extensive transmetallation process (Figure 7). The rate and extent of this process increases with buffer concentration. However, at higher buffer concentrations, the kinetic stability of $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ towards $Zn^{2+}$ transmetallation is higher than that of $[Gd(4\text{-Me-EPTPA})(H_2O)]^{2-}$, but is still much lower than that of C9- and C4 phenyl-substituted $[Gd(EPTPA)(H_2O)]^{2-}$ derivatives.[28]

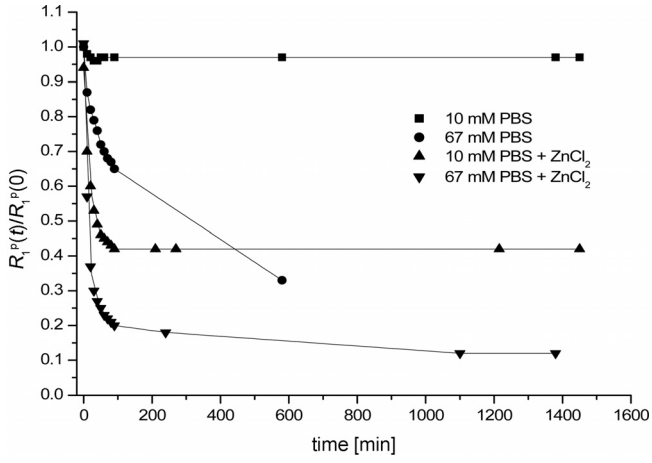

Figure 7. Time evolution of the proton relaxation rate of 2.5 mM $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ (20 MHz, 310 K, pH 7.1) in (■) 10 mM PBS, (●) 67 mM PBS, (▲) 10 mM PBS and 2.5 mM of $ZnCl_2$, and (▼) 67 mM PBS and 2.5 mM of $ZnCl_2$.

## Conclusions

We have devised a new synthetic route to the ligand 4-(*S*)-hydroxymethyl-3,6,10-tri(carboxymethyl)-3,6,10-triazadodecanoic acid, $H_5EPTPACH_2OH$. The fully protected precursor compound **5** is a versatile block for conjugation to biological moieties for targeting purposes and/or optimization of $\tau_r$, as demonstrated before.[23] The hydroxymethyl group allows the construction of potentially responsive contrast agents through enzymatic activation of cleavable bonds such as ester, phosphodiester, and glycosidic bonds. Moreover, although we have not attempted to functionalize the complex of the deprotected ligand **1**, we envisage that this could be an interesting approach to the (enzymatic) synthesis of conjugates that cannot resist the usual harsh deprotection conditions.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Potentiometry studies reveal that the ligand displays slightly higher protonation constants relative to those for the ligand $DTPA^{5-}$, which is consistent with the fact that polyamines with increasing chain length usually display increasing protonation constants. NMR pH titrations give some insight into the ligand microscopic protonation scheme. The first protonation occurs at the more basic central nitrogen atom preferentially over the terminal ones, as was also found for $DTPA^{5-}$. In the second protonation step, there is a preference for the terminal trimethylene and ethylene nitrogen atoms over the central nitrogen atom. Moreover, protonation at the ethylene nitrogen atoms is less favored because of the steric effect of the C4 substituents.

The stability constant (log $K_{GdL}$ = 16.7) for the $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ complex is two orders of magnitude lower than that for the $[Gd(EPTPA)(H_2O)]^{2-}$ complex, which indicates the destabilizing effect of the $CH_2OH$ group on the EPTPA backbone.

$^1H$ NMR studies of the $Ln^{III}$ chelates of these ligands in aqueous solution unambiguously show two sets of high and low intensity resonances, despite being too complex to be assigned, which confirms the presence of two isomeric complexes, one of much higher population than the other.

The water-exchange rate obtained for $[Gd(EPTPA-CH_2OH)(H_2O)]^{2-}$ is close to the theoretically derived optimal value that gives the highest proton relaxivities of $Gd^{III}$-based contrast agents. Despite the optimization of the water-exchange rate, the corresponding proton relaxivities are limited by a far from optimal rotational correlation time.

This ligand offers the possibility for conjugation of slowly rotating moieties through the hydroxymethyl handle, therefore this allows the design of $Gd^{III}$-based contrast agents with simultaneous optimization of the water-exchange rate and rotational correlation time. This approach has been previously applied to the synthesis of the $[Gd(EPTPAC16)(H_2O)]^{2-}$ complex.[23]

The kinetic stability of $[Gd(EPTPACH_2OH)(H_2O)]^{2-}$ in phosphate-buffered solutions towards $Zn^{2+}$ transmetallation is quite low, but higher than that of $[Gd(4\text{-}Me\text{-}EPTPA)(H_2O)]^{2-}$.[28]

## Experimental Section

**Materials and Equipment:** Chemicals of the highest analytical grade were purchased from Sigma–Aldrich and were used without further purification. Solvents used were of reagent grade and purified by the usual methods. Reactions were monitored by TLC on Kieselgel 60 $F_{254}$ (Merck) and products were detected by examination under UV light (254 nm) and by adsorption of iodine vapor. $^1H$ and $^{13}C$ NMR spectra (assigned by 2D DQF-COSY and HMQC techniques) were recorded with a Varian Unity Plus 300 NMR spectrometer operating at 299.938 MHz and 75.428 MHz for $^1H$ and $^{13}C$, respectively. For $^1H$ and $^{13}C$ NMR spectra recorded in $D_2O$, chemical shifts ($\delta$) are given in ppm relative to sodium 3-(trimethylsilyl)propanesulfonate (TSP) as internal reference ($^1H$, $\delta$ = 0.0 ppm) and *tert*-butanol as external reference ($^{13}C$, $CH_3$ $\delta$ = 30.29 ppm). $^{13}C$ NMR spectra were proton broad-band decoupled by using a GARP-1 modulated decoupling scheme. Mass spectrometry measurements were performed with an APEX III FT-ICR MS (Bruker Daltonics, Billerica, MA), equipped with a 7-T actively shielded magnet. Ions were generated by using an Apollo API electrospray ionization (ESI) source (Bruker Daltonics, Billerica, MA). Samples were prepared by applying a spray solution of 50:49.5:0.5 (v/v/v) water/methanol/formic acid at a v/v ratio of 1 to 5%. Data acquisition and data processing were performed with the XMASS software, version 6.1.2 (Bruker Daltonics).

### Synthesis and Characterization

**Compounds 2, 3, 4 and 5:** The synthesis of compounds **2**, **3**, **4**, and **5** was described previously by us.[23]

**Compound 1:** Purified compound **5** (2.32 g, 5.98 mmol) was stirred overnight at room temperature with 6 M HCl/EtOH (1:1, 40 $cm^3$) to afford the title compound in a quantitative yield. As the precursor, fully protected compound **5** was of analytical purity, as demonstrated before,[23] no further purification of the deprotected final compound **1** was judged necessary. $^1H$ NMR (300 MHz, $H_2O$, pH = 5.26): $\delta$ = 2.14 (m, 2 H, $NCH_2CH_2CH_2$), 2.99–3.72 [m br., 9 H, overlapping signals from $NCH_2CH_2CH_2$; $OHCH_2NCHCH_2N$], 3.60 (s, 4 H, terminal acetate protons linked to the ethylene bridge), 3.65 (s, 2 H, central acetate protons), 3.87 (s, 4 H, terminal acetate protons linked to the propylene bridge) ppm. $^{13}C$ (5.6 MHz, $D_2O$): $\delta$ = 23.12 ($NCH_2CH_2CH_2N$), 54.11, 55.86, 56.30 and 57.78 (signals from $NCH_2CH_2CH_2N$ and from $HOCH_2CHCH_2$), 56.70 [$N(CH_2CO_2H)_2$], 60.07 [$N(CH_2CO_2H)_2$], 61.73 ($NCH_2CO_2H$, central acetate), 63.68 ($NCHCH_2N$), 173.32, 175.92 and 180.22 ($CO_2H$) ppm. HRMS ($ESI^+$): calcd. for $C_{16}H_{28}N_3O_{11}$ $[M + H]^+$ 438.1725680; found 438.1718352.

### Protonation and Stability Constants Determined by Potentiometry

Ligand protonation constants were determined at constant ionic strengths [1.0 M KCl for $H_5EPTPACH_2OH$ and 0.1 M $(CH_3)_4NCl$ for $H_5EPTPAC16$]. The ligand solutions (5 $cm^3$ $H_5EPTPACH_2OH$ and 3 $cm^3$ $H_5EPTPAC16$), stirred continuously, were titrated in a thermostatted cell (25 ± 0.2 °C) under a constant stream of $N_2$ by using 0.25 M ($H_5EPTPACH_2OH$) and 0.05 M ($H_5EPTPAC16$) standardized solutions of KOH as the titrants in a Metrohm Dosimat 776 and 665 automatic burette. Combined glass electrodes (Metrohm 6.0234.100 and C14/02-Sc, Ag/AgC1 reference electrode in 3 M KCl; Moeller Scientific Glass Instruments, Switzerland) connected to a Radiometer pHM93 reference pH meter and Metrohm 692 pH/ion meter were used to measure the pH. Protonation constants were determined at 0.002 M and 0.003 M ligand concentrations from two-two parallel titrations. The exact concentration of the $H_5EPTPACH_2OH$ stock solution was also determined potentiometrically. During the ligand titration, after the observation of the first equivalent point, a 25-fold excess of $Ca^{II}$ ions were injected into the sample. The large excess of $Ca^{II}$ liberated the protons that remained on the ligand, and a second equivalent point was observable. The two ligand equivalent protons between the two equivalent points can be determined (see Figure 2). For determination of the stability constants of the [Gd(EPTPACH2OH)-$(H_2O)]^{2-}$ complex, solutions containing the ligand and $Gd^{III}$ in equimolar concentrations were titrated directly with KOH. The hydrogen ion concentration was calculated from the measured pH values by using the correction method suggested by Irving et al.[48] Data treatment and processing was done with the program PSEQUAD.[49]

### NMR pH Titrations

Solutions of the ligands (11.8 mM) for NMR pH titrations were made in $D_2O$ (99.8%), and the pD was adjusted with DCl or $CO_2$-free NaOD. The final pD values were measured on a HANNA

8417 pH meter with a HI1310 combined electrode (HANNA instruments, Italy) and converted to pH values by using the isotopic correction pH = pD – 0.4.[50] $^1$H NMR (1D and 2D COSY) spectra for the pH titrations were carried out with a Varian Unity Plus 300 NMR spectrometer operating at 299.938 MHz at a probe temperature of 25 ± 0.5 °C. Chemical shifts ($\delta$) are given in ppm relative to TSP as internal reference.

**$^1$H NMR of [Ln(EPTPACH$_2$OH)]$^{2-}$:** To an aqueous solution of the ligand (pH = 5.0) was added dropwise an aqueous solution of the corresponding $LnCl_3$ in a1:1 mol ratio. The pH was kept at about 5.0 by the addition of aqueous KOH, and the solution was stirred at room temperature for 1 h. The pH was then adjusted to 7.0 by the addition of KOH (aqueous solution). The solution was concentrated under reduced pressure. The solutions for NMR measurements were obtained by dissolution of the solid complexes obtained previously in $D_2O$ ($V$ = 1 cm$^3$) to obtain 30 mM concentrations. Proton 1D and 2D COSY spectra of the solutions of the diamagnetic ($La^{III}$, $Lu^{III}$, and $Y^{III}$) and paramagnetic ($Pr^{III}$, $Nd^{III}$, $Sm^{III}$, $Eu^{III}$, $Tb^{III}$, $Dy^{III}$, and $Yb^{III}$) complexes were obtained at 7, 25, 60, and 80 °C with Varian Unity Plus 300 (299.938 MHz) and Varian Unity 500 (499.826 MHz) NMR spectrometers.

**$^{17}$O NMR, NMRD and EPR Experiments**

**Sample Preparation:** The $Gd^{III}$ chelate of EPTPACH$_2$OH (for $^{17}$O NMR and NMRD) was prepared by mixing equimolar amounts of $GdCl_3$ and the ligand. A slight excess (5%) of ligand was used, and the pH of the stock solution was adjusted by adding aqueous NaOH (0.1 M). The solution was allowed to react for 1 h at room temperature. The absence of free metal was checked in each sample by testing with xylenol orange.[51] $^{17}$O-enriched water ($^{17}$O: 11.4%) was added to the solutions for the $^{17}$O measurements to improve the sensitivity. The final solution concentration was 25.39 mmol kg$^{-1}$ at pH 6.89. For the NMRD experiments, 6.99 mM solutions at pH 6.18 were used.

**$^{17}$O NMR Experiments:** Variable-temperature $^{17}$O NMR measurements were performed with a Bruker Avance-200 (4.7 T, 27.1 MHz) spectrometer, and a BVT-3000 temperature-control unit was used to stabilize the temperature that was measured by a substitution technique. The samples were sealed in glass spheres that fitted into 10-mm o.d. NMR tubes to eliminate susceptibility corrections to the chemical shifts.[52,53] Longitudinal relaxation rates $1/T_1$ were obtained by the inversion recovery method, and transverse relaxation rates $1/T_2$ by the Carr–Purcell–Meiboom–Gill spin-echo technique. As an external reference, acidified water of pH 3.4 was used.

**NMRD Measurements:** The measurements were performed by using a Stelar Spinmaster FFC NMR relaxometer (0.01–20 MHz) equipped with a VTC90 temperature control unit. At higher fields, the $^1$H relaxivity measurements were performed with Bruker Minispecs mq30 (30 MHz), mq40 (40 MHz), and mq60 (60 MHz) instruments. In each case, the temperature was measured by a substitution technique. Variable-temperature measurements were performed at 25 and 37 °C.

**EPR Spectroscopy:** The X-band (0.34 T, 9.4 GHz) EPR spectra were recorded with a Bruker ESP 300E spectrometer. The spectra were recorded at 25 °C on a quartz flat cell at four different concentrations (23 mM, 10 mM, 5 mM, 1 mM) of aqueous [Gd(EPTPACH2OH)(H$_2$O)]$^{2-}$, pH 6.8 The frequency was calibrated with diphenyl picrylhydrazyl (dpph), and the magnetic field with $Mn^{II}$ in MgO. The transverse electronic relaxation rates, $1/T_{2e}$, were calculated from the EPR linewidths according to Reuben.[54]

**Transmetallation:** Transmetallation by $Zn^{2+}$ ions was evaluated by the decrease in the water proton longitudinal relaxation rate, at 310 K and 20 MHz (Bruker Minispec mq20), of phosphate-buffered solutions (PBS, pH 7.1, 10 mM or 67 mM) containing 2.5 mM of [Gd(EPTPACH$_2$OH)(H$_2$O)]$^{2-}$ and 2.5 mM of $ZnCl_2$.[47] The water longitudinal relaxation rate was also measured on PBS-buffered solutions (pH 7.1, 10 mM and 67 mM) containing 2.5 mM of [Gd(EPTPACH$_2$OH)(H$_2$O)]$^{2-}$.[28]

**Data Analysis:** The simultaneous least-squares fittings of the $^{17}$O NMR and NMRD relaxation data were performed with the Visualiseur/Optimiseur programs on a Matlab platform version 6.5.[55]

**Supporting Information** (see footnote on the first page of this article): Equations used for the determination of the relaxivity parameters from the analysis of NMRD and $^{17}$O NMR spectroscopic data; Tables used for the determination of the microscopic protonation scheme of the ligands, which contain the pH dependence of the proton chemical shifts for H$_5$EPTPACH$_2$OH (Table S1) and H$_5$EPTPAC16 (Table S2), Table detailing the calculated percent protonation fractions of the different basic sites of H$_5$EPTPACH$_2$OH and H$_5$EPTPAC16 for different values of $n$ (for identification of $f_n$ sites see Figure 1) and listing the reported values for H$_5$EPTPA (Table S3), Tables containing the frequency dependence of the water proton relaxivities of [$Gd^{III}$(EPTPACH$_2$OH)(H$_2$O)]$^{2-}$ at two temperatures (Table S4), and the variable temperature reduced transverse and longitudinal $^{17}$O relaxation rates and chemical shifts of [Gd(EPTPACH$_2$OH)(H$_2$O)]$^{2-}$ solution at 4.7 T (Table S5); 300 MHz $^1$H NMR spectra of [Ln(EPTPACH$_2$OH)]$^{2-}$ complexes in $D_2O$ (30 mM, pH 7.0, $T$ = 25 °C): a) $Nd^{III}$ complex, b) $Eu^{III}$ complex, c) $Sm^{III}$ complex, d) $Y^{III}$ complex (Figure S1) and 500 MHz $^1$H COSY spectra of [Ln(EPTPACH$_2$OH)]$^{2-}$ complexes in $D_2O$ (30 mM, pH 7.0, $T$ = 25 °C), from top to bottom: $Y^{III}$ complex, $Nd^{III}$ complex, $Sm^{III}$ complex (Figure S2).

# Coordination Alternatives in Dinuclear Bis(pyridin-2-ylalkyl)-benzylaminecopper(II) Complexes with $OH^-$, $RO^-$, $F^-$, or $Cl^-$ Bridges: Experimental Structures and DFT Preferences

**Jorge Manzur,*[a] Andrés Vega,*[b] Ana María García,[a] Carolina Acuña,[a] Monika Sieger,[c] Biprajit Sarkar,[c] Mark Niemeyer,[c] Falk Lissner,[c] Thomas Schleid,[c] and Wolfgang Kaim*[c]**

**Keywords:** Copper / EPR spectroscopy / Isomerism / N ligands / Structure

The compounds $[L^1Cu(\mu\text{-}OH)_2CuL^1](ClO_4)_2$ (**1**), $[L^2Cu(\mu\text{-}OH)_2CuL^2](ClO_4)_2$ (**2**), $[L^3Cu(\mu\text{-}OH)_2CuL^3](ClO_4)_2$ (**3**), $[L^3Cu(\mu\text{-}OMe)_2CuL^3](ClO_4)_2$ (**4**), $[L^3Cu(\mu\text{-}F)_2CuL^3](BF_4)_2$ (**5**), $[L^4Cu(\mu\text{-}Cl)_2CuL^4](ClO_4)_2$ (**6**), and $[Cu(\mu\text{-}L^5)_2Cu](ClO_4)_2$ (**7**), where $L^1$ = bis(pyridin-2-ylmethyl)benzylamine, $L^2$ = (6-methylpyridin-2-ylmethyl)(pyridin-2-ylmethyl)benzylamine, $L^3$ = bis(6-methylpyridin-2-ylmethyl)benzylamine, $L^4$ = (pyridin-2-ylethyl)(pyridin-2-ylmethyl)benzylamine, and $L^5$ = (6-oxidomethylpyridin-2-ylmethyl)(6-methylpyridin-2-ylmethyl)benzylamine, were structurally characterized and studied by low-temperature EPR spectroscopy. The formation of compound **5** involved fluoride abstraction from $BF_4^-$ and that of **7** involved $O_2$-assisted C–H (methyl) activation/monooxygenation of $L^3$. Whereas the dications of **1**–**4** and **7** possess a square-pyramidal configuration at the copper(II) centers with hydroxide or alkoxide bridges in equatorial positions, the dications of **5** and **6** exhibit equatorial/axial arrangements for the bridging halide ions. In the dication of **5**, the tridentate ligand binds in a meridional fashion and includes two adjacent five-membered chelate rings. Such a situation has been observed previously only with chloride, alkoxide, or aqua bridges. In contrast to the *syn* configuration of the dication of **2**, the dications of complexes **1**, **3**, **4**, and **7** adopt an *anti* configuration with respect to the binding of $L^n$. The dications of **1**, **2**, and **7** have the pyridinyl or 6-methylpyridinyl groups in the axial position, whereas those of **3** and **4** feature the tertiary amine N atom at that site. DFT calculations of various configurations of the dications of **1**–**6** reproduce the experimentally observed structural alternatives in complexes **1**–**4**, but they do not predict the axial/equatorial structure of **5** as the lowest-energy configuration. The systematic overestimation of repulsive forces and thus of distances by DFT may result in an underestimation of the π-π interaction between the largely coplanar *mer*-$L^3$ ligands separated by about 3.6 Å in **5**, which probably affects its structure. By incorporating these and previous results, the *syn* versus *anti*, equatorial/equatorial versus equatorial/axial, and axial pyridine versus axial amine structural alternatives are discussed.

## Introduction

Bis(hydroxido)-bridged dicopper(II) complexes are among the most typical products from reactions between copper(I) compounds and molecular oxygen.[1–8] The reactions of $Cu^I$ with $O_2$ have found interest in synthesis because of their potential use in the hydroxylation of aromatic and other organic compounds.[9] In $O_2$ transport proteins[10] and oxygenation or oxidoreductase enzymes,[11,12] however, the formation of bis(hydroxido)dicopper(II) products is usually avoided to ensure reversibility. Among the most widely used copper coligands in this context are the tridentate bis(pyridin-2-ylalkyl)amines,[2,3,6,7a] which can be modified in terms of their steric bulk, electronic effects, and alkyl chain lengths, which thus allows tridentate coordination in both facial[2a,2b,13] and meridional fashions.[2b–2d] In contrast, the equally popular[6] tris(pyrazolyl)borate,[4] tris(pyrazolyl)methane,[7b] and triazacyclononane ligands[5] are restricted to facial coordination.

The formation of copper(II) [or copper(III)][6] species after the interaction of $O_2$ and $Cu^I$ is accompanied by the typical structural peculiarities of the $d^9$ (or $d^8$) configuration, that is, the tendency to form approximately square-

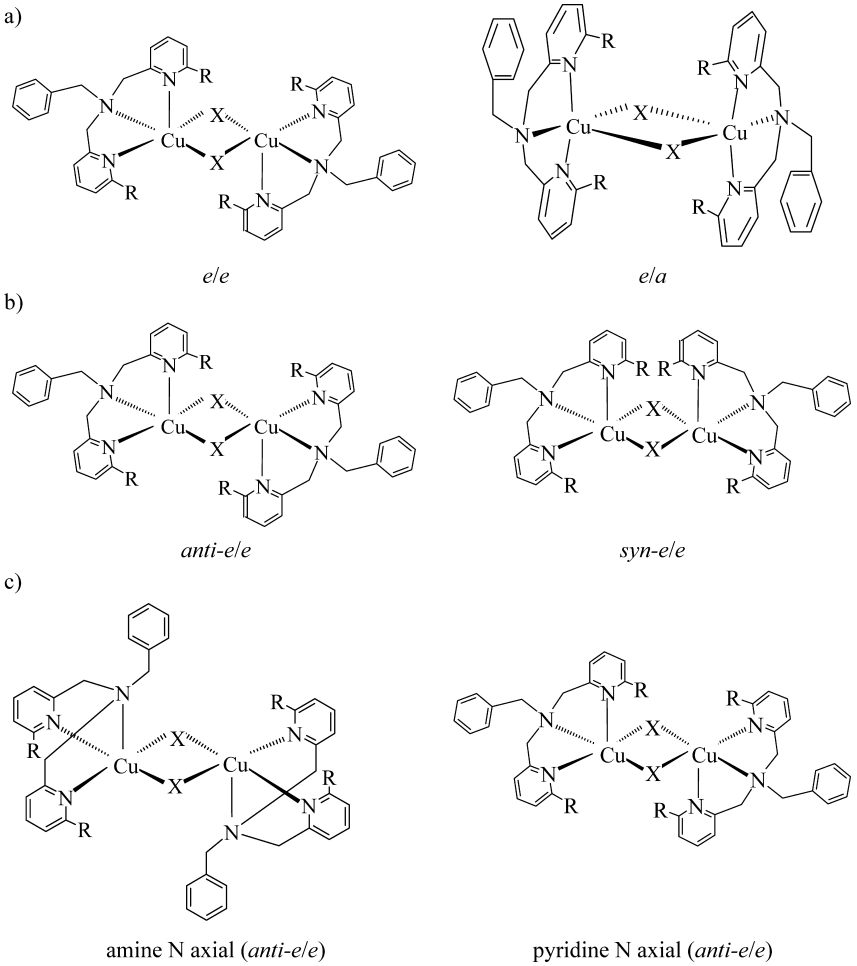
pyramidal structures with significantly different equatorial (*e*) and axial (*a*) binding sites.[6] Because tridentate chelating ligands restrict rapid interconversion, there are clear structural alternatives for doubly bridged dicopper(II) systems, viz., the *e*/*e* or *e*/*a* situations (Scheme 1a). Whereas the *e*/*e* conformation typically shows a rather symmetrical bridging arrangement with $Cu^{II}$–OH distances of about 1.93 Å,[2a,2b,3–5,7a,13] the much longer axial bonds extend to 2.25–2.30 Å for the few *e*/*a* examples described so far.[2b–2d,14] These isolated examples were formulated as containing six-membered chelate rings with relaxed N–Cu–N bite angles of about 90°.[2b–2d] Examples with smaller chelate rings were restricted to chlorido-, alkoxido-, and aqua-bridged species.[7a,15]

In a detailed analysis of the original assertion of a bis(hydroxido)-bridged dicopper(II) complex with an *e*/*a* arrangement, [2b] Lee and Holm showed[14] that bridging by two fluoride ions abstracted from $PF_6^-$ − perhaps by a $Cu/O_2/H_2O$-assisted process − may instead account for the observed configuration. In addition, these authors reported the formation of small amounts of a dicopper(II) complex doubly bridged by a tetradentate anionic monooxygenated ligand generated by the activation of benzylic $CH_2$.[14]

For the more common[16] $[L^nCu(\mu\text{-}X)_2CuL^n]^{2+}$ systems with *e*/*e* configurations of the bridging ligands, two further kinds of structural alternatives are established: the axial ligands may be arranged in an *anti* or *syn* orientation relative to the $Cu(\mu\text{-}X)_2Cu$ plane (Scheme 1b),[7a] and the unsymmetrical tridentate bis(pyridin-2-ylalkyl)amine ligands may bind with the pyridine or the amine N atoms in the axial position (Scheme 1c).[2a]

In this contribution we describe seven additional examples of these kinds of $[L^nCu(\mu\text{-}X)_2CuL^n]^{2+}$ complexes, which may shed light on the structural alternatives delineated above. Of the compounds $[L^1Cu(\mu\text{-}OH)_2CuL^1](ClO_4)_2$ (**1**), $[L^2Cu(\mu\text{-}OH)_2CuL^2](ClO_4)_2$ (**2**), $[L^3Cu(\mu\text{-}OH)_2CuL^3](ClO_4)_2$ (**3**), $[L^3Cu(\mu\text{-}OMe)_2CuL^3](ClO_4)_2$ (**4**), $[L^3Cu(\mu\text{-}F)_2CuL^3](BF_4)_2$ (**5**), $[L^4Cu(\mu\text{-}Cl)_2CuL^4](ClO_4)_2$ (**6**) and $[Cu(\mu\text{-}L^5)_2Cu](ClO_4)_2$ (**7**), where $L^1$ = bis(pyridin-2-ylmethyl)benzylamine, $L^2$ = (6-methylpyridin-2-ylmethyl)(pyridin-2-ylmethyl)benzylamine, $L^3$ = bis(6-methylpyridin-2-ylmethyl)benzylamine, $L^4$ = (pyridin-2-ylethyl)(pyridin-2-ylmethyl)benzylamine, and $L^5$ = (6-oxidomethylpyridin-2-ylmethyl)(6-methylpyridin-2-ylmethyl)benzylamine, complexes **1**–**3** and **7** were obtained from treatment of in situ generated copper(I) precursors $[L^nCu(L')]^+$ with air (L′: solvent). The ligands except for $L^5$ were described in the literature,[7a,17] as were some of the copper(I) precursors.[17] An additional copper(I) compound, $[L^3Cu(PPh_3)](BF_4)$, is described here for comparison with the recently



Scheme 1.

reported $[L^3CuL']$($BF_4$) species, where L′ = $CH_3CN$ or CO.[17] Whereas the oligomethylene chain length in the ligands controls the chelate ring sizes,[18] the 6-methyl substitution at the pyridin-2-yl ring has been reported to decrease its donor ability and slow down the reaction rate due to steric repulsion.[17] Within the $L^1$, $L^2$, and $L^3$ ligand series, substitution at the pyridin-2-yl rings was increased while the five-membered chelate rings were maintained, which thus resulted in a largely planar ligand geometry relative to some previously studied systems.[2b,2d] In the course of these studies we not only encountered the well-established[14,19] fluoride abstraction from $BF_4^-$ to yield an unusual structure for **5**, we also observed small amounts of dimeric product complex **7**, which contained a tetradentate anionic monooxygenated ligand $L^5$, from the reaction involving $L^3$. In contrast to a previous observation,[14] however, the attack had not occurred at the connecting benzylic methylene functionality, but at the α-*methyl* group of the pyridine ring. Such CH activation by $Cu/O_2$ resembles enzymatic processes[14,20] and is studied in the context of synthetic transformations;[9] an alkylperoxidocopper(II) complex resulting from the attack on an α-picolyl methyl group was reported recently.[9e]

To investigate the metal–metal interaction (coupling) and the possible dissociation of the dinuclear complexes in solution,[2b] we studied compounds **1**–**6** by EPR spectroscopy. The dications of compounds **1**–**6** were subjected to DFT calculations of various coordination alternatives in order to confirm their configurational preferences and to understand the stereochemically relevant factors involved.

## Results and Discussion

### Synthesis

Bis(hydroxido)-bridged dicopper(II) complexes **1**–**3** were typically obtained as final products from reactions between in situ generated copper(I) complexes of the ligands after exposure to atmospheric conditions [Equation (1)]. One $Cu^I$ compound, $[L^3Cu(PPh_3)](BF_4)$, was isolated for NMR spectroscopic analysis and structural characterization (cf. below).

$$4\ L^nCu^+ + O_2 + 2\ H_2O \rightarrow 2\ [L^nCu(\mu\text{-}OH)_2CuL^n]^{2+} \quad (1)$$

The lability of the bis(hydroxido)-bridged dicopper(II) complexes in certain solvents allowed simple conversion of **3** into bis(methoxido)-bridged **4** containing the $[L^3Cu(\mu\text{-}OMe)_2CuL^3]^{2+}$ dication. The use of the $[Cu(CH_3CN)_4]$-($BF_4$) precursor led to bis(fluorido)-bridged **5** by well-established[14,19] $F^-$ abstraction from tetrafluoroborate, where the remaining $BF_3$ can act as a Lewis acidic partner for amines. This reactivity has been observed even with $PF_6^-$, a supposedly more inert anion.[14] Both the unambiguous crystallographic signature of $F^-$ versus $OH^-$ and the much more pronounced asymmetry of the central four-membered ring is typical for bis(fluorido)- versus bis(hydroxido)-bridged dicopper(II) complexes (cf. below).[14] Otherwise, halide-bridged complexes such as **6** can be obtained by using the corresponding copper salt. In the absence of an available halide ion for bridging, a secondary reaction may occur that presumably involves the metal-assisted monooxygenation of a partially activated C–H bond. These reactions proceed in low yields.[14] However, whereas Lee and Holm found a product with a monooxygenated benzylic $CH_2$ group from a pyridyl–amine linkage,[14] we observed the monooxygenation of a $CH_3$ group in the α position of the pyridine. The resulting complex **7** thus contains two anionic, tetradentate (6-oxidomethylpyridin-2-ylmethyl)(6-methylpyridin-2-ylmethyl)benzylamine bridges. CH activation by $Cu/O_2$ is currently studied in the context of synthetic transformations[9] and within attempts to elucidate the mechanisms of corresponding enzymes,[20] that is, tyrosinases,[21] for aromatic CH groups and dopamine β monoxygenase or peptidylglycine α-hydroxylating monooxygenase (PHM) for nonaromatic CH groups.[22] These reactions may proceed via mononuclear ($Cu^{II}$-superoxido)[23] or dinuclear ($Cu^{II}$-peroxido)[6,9e] precursor intermediates to yield the reactive copper–oxyl ($O^{\cdot-}$) species that effects the necessary H abstraction before rebound.[24]

### Structure Description

The crystallographic data of the systems studied by X-ray diffraction are summarized in Tables 5 and 6.

Despite the poor data quality, the structure results (bond lengths and angles; Tables 1 and 2) for $[L^3Cu(PPh_3)](BF_4)$ indicate that the corresponding complex cation possesses an intermediate structure between those of $[L^3Cu(CH_3CN)]^+$ and $[L^3Cu(CO)]^+$.[17] This reflects the moderately lower π-acceptor ability of $PPh_3$ relative to that of CO. The overall structure of this complex (Figure 1) remains that of a highly distorted tetrahedron,[17] which can be alternatively described as a trigonal pyramid with the more weakly bonded amine N atom at the apex.

Among the bis(hydroxido)-bridged dicopper(II) complexes with nearly square-pyramidal configurations ($\tau < 0.20$),[25] compounds **1**–**3** (Figures 2, 3, and 4; Table 1) exhibit the familiar *e/e* configuration[2a,2b,3–5,7a] for the rather symmetrically bonded hydroxide bridges. However, whereas **1** and **3** show *anti*-positioned axial (6-methyl)pyridin-2-yl ligands, the 6-methylpyridin-2-yl axial ligands in **2** were found in a *syn* configuration and face each other with the smallest distance between the methyl-substituted ring C6′ and C6′′ carbon atoms measuring 3.57 Å (Figure 3). The least-squares planes defined by the apical rings (N1′, C2′, C3′, C4′, C5′, C6′ and N1′′, C2′′, C3′′, C4′′, C5′′, C6′′) are not completely parallel; they adopt a small dihedral angle of 4.2(1)°. The distances between the centroids of each ring and the neighboring planes are 3.44 and 3.50 Å, respectively.

The preference of the sterically more demanding 6-methylpyridin-2-yl group for the axial position is not unexpected, and the tendency of unactivated pyridines to adopt this position has been reconfirmed recently.[2a] However, with strong donor substituents such as OR or $NR_2$ in the *para*

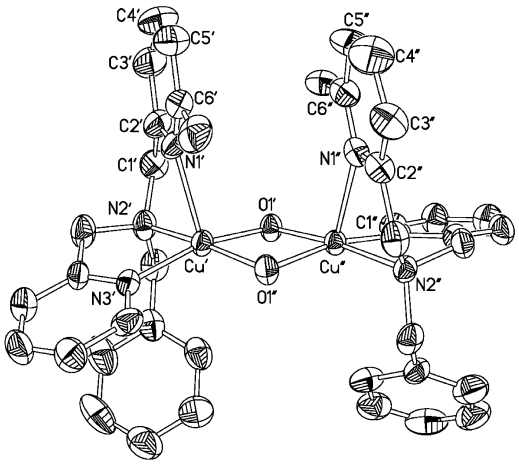

Figure 3. Molecular structure of the dication in the crystal of $[L^2Cu(\mu\text{-}OH)_2CuL^2](ClO_4)_2 \cdot H_2O$ (**2**).

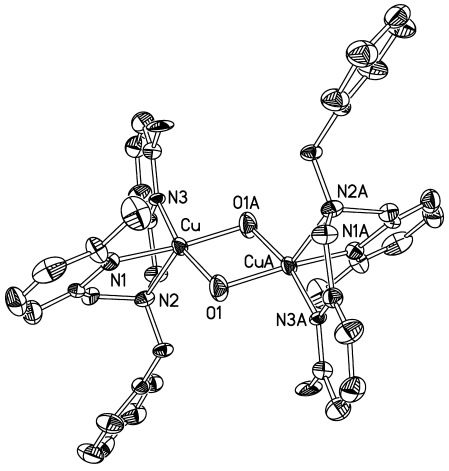

Figure 4. Molecular structure of the dication in the crystal of $[L^3Cu(\mu\text{-}OH)_2CuL^3](ClO_4)_2$ (**3**).

position, the pyridines may prefer the equatorial coordination, leaving the axial binding site for the trialkylamine N atom.[2a] The *syn* configuration for **2** is reminiscent of that of a 6-trifluoromethyl-substituted analogue,[7a] which suggests that there is an attractive interaction.

The related hydroxido- and methoxido-bridged structures **3** and **4** (Figures 4 and 5, respectively) are very similar in their *anti* configurations, which are almost superimposable. The Cu–O distances are a bit shorter for **3** [1.891(2), 1.905(2) Å] than for **4** [1.930(2), 1.933(2) Å]. The methoxy carbon atoms of the OMe groups lie at opposite sides of the central $Cu_2O_2$ plane in **4** and are almost coplanar. The C–O vector defines an angle of only 7.9° with the plane.

As pointed out before,[2d] bis(chlorido)-bridged dicopper(II) complexes can readily adopt the *e/a* arrangement for the bridges with long axial Cu–Cl distances of about 2.8 Å. A previous study of $[L^1Cu(\mu\text{-}Cl)_2CuL^1](ClO_4)_2$ (**8**) showed[7a] that this also holds when two five-membered chelate rings are formed in the $L^n$Cu moiety. Compound

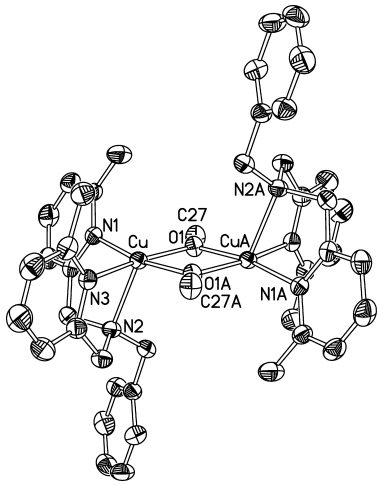

Figure 5. Molecular structure of the dication in the crystal of $[L^3Cu(\mu\text{-}OMe)_2CuL^3](ClO_4)_2$ (**4**).

**6**, $[L^4Cu(\mu\text{-}Cl)_2CuL^4](ClO_4)_2$, described here shows that the same kind of structure is obtained after lengthening either one of the alkyl chains that connects the amine N atom or the pyridin-2-yl moiety from $CH_2$ to $CH_2CH_2$ (Figure 6, Table 2).

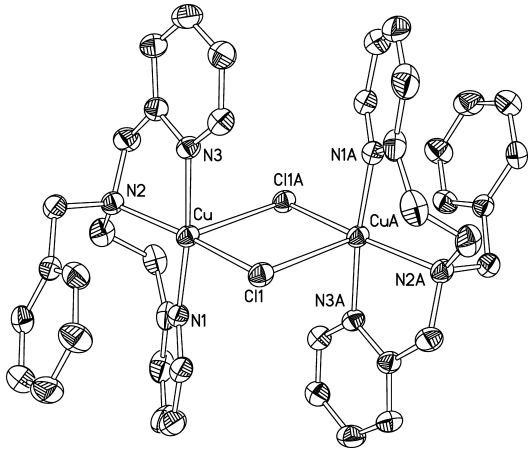

Figure 6. Molecular structure of the dication in the crystal of $[L^4Cu(\mu\text{-}Cl)_2CuL^4](ClO_4)_2$ (**6**).

In contrast to $\mu\text{-}Cl^-$, $\mu\text{-}OR^-$, and $\mu\text{-}OH_2$, the smaller $\mu\text{-}OH^-$ bridges typically favor the *e/e* configuration in dinuclear $[(\eta^3\text{-}L)Cu(\mu\text{-}OH)_2Cu(\eta^3\text{-}L)]^{2+}$ complexes. The tridentate ligands will then coordinate in a facial mode. This rule is not only confirmed by the revision of the initially assigned hydroxido-bridged complex with the *e/a* configuration[2b] to a fluorido-bridged species,[14] but it is also corroborated by the examples presented here, viz., an *e/e* configuration for **3** and **4** but an *e/a* configuration for fluorido-bridged **5** (Figure 7). Nevertheless, the latter is surprising because meridional binding of tridentate ligands such as $L^3$ is less favorable due to the necessity to form two adjacent five-membered chelate rings (Table 2).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

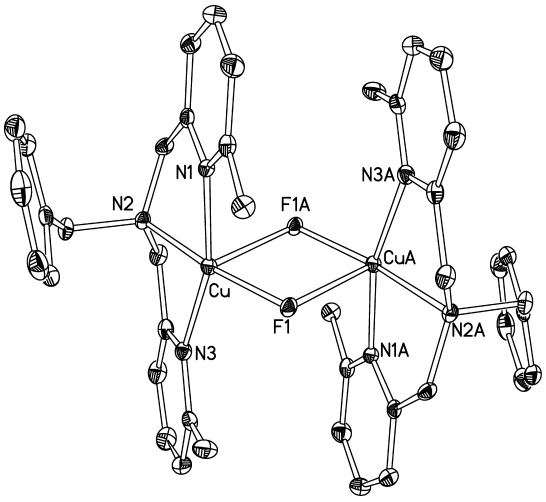

Figure 7. Molecular structure of the dication in the crystal of $[L^3Cu(\mu\text{-}F)_2CuL^3](BF_4)_2{\cdot}2CH_2Cl_2$ (**5**).

According to the five-membered chelate ring situation, the N–Cu–N angles in **5** have decreased to about 83° and the *trans*-N1–Cu–N3 angle to 163.79(7)°. Measuring 169.10(6)°, the other *trans*-N2–Cu–F1 angle is distinctly more linear, as is the N1–Cu–N3 angle for the *mer*-coordinated $L^4$ in compound **6**, which measures 172.0(2)°. All Cu–N bond lengths in **5** lie around 2.02 Å; the typically weaker bonding to the amine N atom is compensated for by its preferred central position in *mer*-$L^3$. In contrast, the difference between the short equatorial Cu–F bond length and the typically[14] long axial Cu–F distance is almost 0.4 Å. The molecular dication of **5** has inversion symmetry (Figure 7), and the central $Cu_2F_2$ ring approaches a rectangular geometry because the bond lengths differ widely but the Cu–F1–CuA and F1–Cu–F1A angles [97.74(5) and 82.26(5)°, respectively] do not strongly deviate from 90°. Measuring 3.134(1) Å, the Cu–CuA distance is longer than the corresponding distances in the *e*/*e*-configured hydroxido

derivatives **1**–**3** (<3.01 Å), but much smaller than those in the chlorido-bridged **6** [3.714(1) Å] and **8** [3.566(1) Å],[7a] and that reported for a complex involving nonplanar, six-membered chelate rings (3.271 Å).[2d] In fact, the virtually planar $L^3Cu^{II}$ moieties in **5** are arranged in a parallely stacked structure (dihedral angle of 4.5°) with partially overlapping pyridyl-ring π systems and oppositely oriented methyl groups. The interplanar distance of about 3.6 Å (vs. 3.35 Å in graphite) indicates a π–π interaction that probably induces and stabilizes[2b] the structure. π–π interactions have been implicated before in similar complexes,[2b] and relatively long interplanar distances are typical for nitrogen-containing aromatic molecules.[26] The aromatic rings of the benzyl substituents in **5** also overlap with the pyridyl rings (dihedral angle of 21.4°) with interplanar distances (e.g. 3.068 Å for N1–C21) that allow such π–π interactions. In total, a π–π–π arrangement (pyridyl, pyridyl, benzyl) results that is reminiscent of a recently described dicopper(I) complex involving phenylphosphane and bipyrimidine π systems.[27]

Complex **7** in which the $L^3$ ligand has undergone monooxygenation at a picolyl methyl group and then deprotonation to yield tetradentate anionic $L^5$ (Scheme 2) shows the familiar *anti* configuration of the *e*/*e* arrangement, with the nonmonooxygenated 6-methylpyridyl group in the axial position (Figure 8). Because of the restriction by tetrachelation, the square planar configuration is slightly more distorted ($\tau = 0.28$) than in the other cases ($\tau < 0.20$). Table 3 summarizes the experimentally observed coordination situations, and the following discussion is concerned with the possible predictability of such structural preferences.

### DFT Calculations for the $[L^nCu(\mu\text{-}X)_2CuL^n]^{2+}$ Dications

The variety of structural alternatives for these complexes (Scheme 1, Table 3) and their realization under different conditions have prompted us to undertake a DFT calculation study to rationalize the experimental results and to explore the predictive potential of the method. Table 3 summarizes the energies calculated for the different stereoisomers, and the DFT-calculated structure parameters are found in Table S1 (Supporting Information).

As can be expected just by considering steric hindrance, dicopper(II) complexes sharing an edge of the two square-based pyramids favor the *anti* arrangement for the apical ligands. For the dication of **1**, $[L^1Cu(\mu\text{-}OH)_2CuL^1]^{2+}$, the *anti*-*e*/*e* structure with pyridine or amine nitrogen atoms in the apical position should be expected. The X-ray structure shows a pyridyl *anti*-*e*/*e* geometry for this complex (as a perchlorate salt). DFT results predict this isomer to be 0.006 eV higher in energy than the most stable *anti*-*e*/*e* amine configuration. Both these isomers are practically of the same energy, so packing could play an important role in determining the observed crystal structure. The *syn*-*e*/*e* isomers for the complex are 0.041 and 0.121 eV higher in energy that the most stable configuration. The *e*/*a* isomer was computed to be 0.723 eV less stable than the *anti*-*e*/*e* pyridyl isomer. Interestingly, the *anti*-*e*/*e* pyridyl configuration is preserved when complex **2** is crystallized as an aqua solvate instead of the acetone solvate described in the text, where the packing interactions must be completely different.

Replacement of one α-hydrogen atom on one of the pyridyl groups of $L^1$ by a methyl group leads to $L^2$. The dication of **2**, $[L^2Cu(\mu\text{-}OH)_2CuL^2]^{2+}$, crystallizes in the *syn*-*e*/*e* pyridyl geometry (with perchlorate counteranions); this was also observed for the trifluoromethyl derivative of $L^2$.[7a] DFT calculations for **2** show that the energy of the *syn*-*e*/*e* pyridyl isomer lies just 0.002 eV above that of the most stable *syn*-*e*/*e* amine alternative. The *anti* configurations are a bit higher in energy, whereas the energy of the *e*/*a* isomer lies about 0.7 eV above that of the most stable isomer. The observed structure may result from $CX_3\cdots$ring interactions that could occur in the *syn* configuration between the substituted pyridine rings. The replacement of the other α-hydrogen atom by a methyl group to give $[L^3Cu(\mu\text{-}OH)_2CuL^3]^{2+}$ (dication of **3**) has a strong effect on the relative energies. In this complex, the *anti*-*e*/*e* amine configuration is computed to be the most stable isomer, and this result coincides with the X-ray determined structure for the perchlorate salt.

Changing the hydroxy bridge into a methoxy one leads to $[L^2Cu(\mu\text{-}OMe)_2CuL^2]^{2+}$[7a] and $[L^3Cu(\mu\text{-}OMe)_2CuL^3]^{2+}$ (dication of **4**), where again the *anti*-*e*/*e* amine form is calculated to be the most stable isomer, and this is confirmed by the X-ray diffraction results. Moreover, the computed energy differences between the most stable isomer and the others are now larger, which suggests that the incorporation of a methyl group on the bridge produces enhanced repulsion.

The complexes $[L^3Cu(\mu\text{-}F)_2CuL^3]^{2+}$ (dication of **5**), $[L^4Cu(\mu\text{-}Cl)_2CuL^4]^{2+}$ (dication of **6**), and $[L^1Cu(\mu\text{-}Cl)_2CuL^1]^{2+}$ (dication of **8**) were studied to test the effect of halide bridges. Their experimental structures correspond to the *e*/*a* isomer. The most stable isomer computed for the dication of **5** is the *anti*-*e*/*e* pyridyl form. Although this result does not fit the experimental observations (*e*/*a* isomer), the difference in energy of this isomer relative to the most stable one at 0.275 eV is noticeably diminished in comparison to the hydroxy or methoxy analogues, where the energy differences between the *e*/*e* and *e*/*a* configurations are of the order of 1 eV. The computational results for the dications of **6** and **8** show that the most stable isomers possess *e*/*a* configurations, which is in agreement with the experimental results.

In conclusion, the DFT method makes a clear distinction between the *e*/*e* and *e*/*a* configurations. Although the calculated energy differences are not very large in the case of some *syn*- and *anti*-*e*/*e* isomers, the DFT method has correctly reproduced the experimentally favored complex configurations except in the case of the dication of **5** where additional, highly distance-dependent π–π interactions are obviously underestimated[26,27] because of the systematic overestimation of distances.

### EPR Spectroscopy

The EPR method is suited to study intramolecular spin–spin interactions of copper(II) ions in dinuclear complexes and to investigate their possible dissociation into mononuclear species in solution.[2b] We therefore studied the compounds by this method in the solid state and in frozen solutions at 110 K (Figure 9, Table 4).

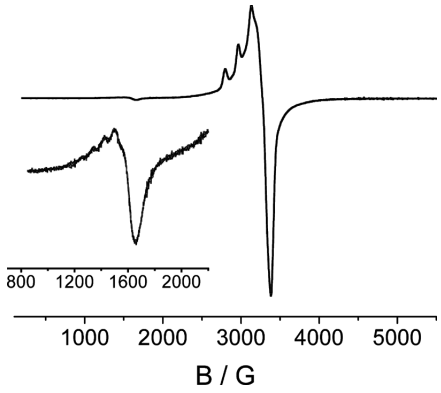

Figure 9. EPR signal of compound $[L^4Cu(\mu\text{-}Cl)_2CuL^4](ClO_4)_2$ (**6**) with half-field component (insert).

Table 4. EPR parameters of complexes in $CH_2Cl_2/CH_3CN$ (*x*/*y*) at 110 K.

[a] In mT. [b] Unresolved signal. [c] Half-field signal. [d] Weak signal. [e] $A_\perp$ = 2.0 mT.

The complexes show typical[2] EPR signals for $Cu^{II}(\mu\text{-}X)_2Cu^{II}$ cores in both cases with the spectra in frozen solutions being better resolved (Figure 9). Under both sets of conditions we could observe half-field transitions for certain compounds, especially for the halide-bridged species possessing a pronounced asymmetry of the Cu(μ-X)Cu core and possible triplet ground states.[7a] The fact that both solid samples and frozen solutions exhibit the half-field signals for the triplet excited states suggests that the dinuclear arrangement remains largely intact in the chosen $CH_2Cl_2/CH_3CN$ solvent mixtures. Preliminary UV/Vis spectroscopic experiments have shown that association and ligand substitution equilibria can occur in media such as alcohols. The differences between the complexes are rather small except for the somewhat higher $A_\parallel$ ($^{63,65}Cu$) and lower *g* values for the chloride-bridged species **6** and **8** (Table 4). The increased copper–halide covalency and the higher spin-orbit coupling contributions from $Cl^-$ are held responsible for these differences.

## Conclusions

During this study of $[L^nCu(\mu\text{-}X)_2CuL^n)]^{2+}$ complex dications, we encountered a remarkable structural variety (Table 3). Nevertheless, DFT calculations were able to confirm the preferred configuration of most of these structures by their computed relative energies except in the case of the $F^-$-bridged complex **5**, where the systematic overestimation of repulsive forces and thus of distances led to wrong predictions as a result of underestimated π–π interactions. Whereas some effects such as the preference of the more weakly basic halide ligands for the axial position are easily rationalized, the differences between the *anti* and *syn* orientations or the preferred N donor for the axial position are not readily obvious. Karlin and coworkers noted that "such structural differences or variations may need to be considered to explain certain aspects of […] reactivity patterns",[2a] and therefore, a detailed computational approach may provide increased efficiency in the design and development of ligands for broader interest such as in metal/$O_2$-induced CH activation;[9] an example encountered accidentally is presented here as doubly monooxygenated complex **7**.

## Experimental Section

**Instrumentation:** EPR spectra in the X band were recorded with a Bruker System EMX. $^1H$ NMR spectra were recorded in $CDCl_3$ with a Bruker AMX-300 NMR spectrometer. IR spectra were obtained with a Bruker Vector 22 instrument.

**Syntheses of Ligands:** The ligands $L^1$ = bis(pyridin-2-ylmethyl)benzylamine, $L^2$ = (6-methylpyridin-2-ylmethyl)(pyridin-2-ylmethyl)-benzylamine, $L^3$ = bis(6-methylpyridin-2-ylmethyl)benzylamine, and $L^4$ = (pyridin-2-ylethyl)(pyridin-2-ylmethyl)benzylamine were prepared according to the literature[7a,17] by reaction of the appropriate secondary amine with benzyl bromide in $CH_3CN$ as the solvent.

#### Synthesis of Copper Complexes

***Caution*:** *Perchlorate complexes are potentially explosive and should be handled with care.*

**$[L^3Cu(PPh_3)](BF_4)$:** To a solution of $L^3$ (55 mg, 0.173 mmol) in $CH_2Cl_2$ (10 mL) was added $[Cu(CH_3CN)_3(PPh_3)]BF_4$ (83 mg, 0.155 mmol). The mixture was stirred at room temperature overnight. After reducing the solvent 3 mL, a bright yellow product precipitated in 79% yield (89 mg) by adding hexane/toluene (1:1). Crystals were obtained by recrystallization from $CH_2Cl_2$ at –20 °C. Single crystals were covered with a layer of viscous hydrocarbon oil (Paratone N, Exxon), attached to a glass fiber, and instantly placed in a low-temperature $N_2$ stream. $^1H$ NMR (300 MHz, $CD_3CN$): δ = 2.62 (s, 6 H), 3.56 (s, 2 H), 3.67 (AB-m, 4 H), 7.08 (br., 2 H), 7.21–7.33 (m, 15 H), 7.37–7.54 (m, 7 H), 7.80 (pt, *J* = 7.7 Hz, 2 H) ppm. $C_{39}H_{38}BCuF_4N_3P$ (730.07): calcd. C 64.16, H 5.25, N 5.76; found C 63.92, H 5.93, N 5.12.

**$[L^3Cu(CH_3CN)](BF_4)$:** To a solution of $L^3$ (100 mg, 0.315 mmol) in $CH_2Cl_2$ (10 mL) was added $[Cu(CH_3CN)_4]BF_4$ (100 mg,

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

0.318 mmol). The mixture was stirred for 2 h at room temperature. After reducing the solvent to 2 mL and adding hexane a partially crystalline and highly air-sensitive precipitate was obtained and dried. Yield: 69 mg (43%). $^1$H NMR (300 MHz, $CD_3CN$): $\delta$ = 2.71 (s, 6 H), 3.81 (AB-m, 4 H), 3.93 (s, 2 H), 7.11 (d, $J$ = 8 Hz, 2 H), 7.25–7.40 (m, 7 H), 7.68 (pt, $J$ = 7.7 Hz, 2 H) ppm.

**$[L^1Cu(\mu\text{-}OH)_2CuL^1](ClO_4)_2\cdot 2CH_3COCH_3$ ($1\cdot 2CH_3COCH_3$):** To a suspension of $[Cu(CH_3CN)_4](ClO_4)$ (654 mg, 2 mmol) in acetone (10 mL) was added an acetone solution of the ligand (579 mg, 2 mmol) under an atmosphere of nitrogen. The mixture was stirred for 30 min to give a yellow solution, and then the flask was opened to the atmosphere. The solution turned blue, and the solid product separated with time. Crystals suitable for X-ray diffraction studies were obtained by recrystallization from boiling acetone. Yield: 697 mg (66%). IR (KBr pellet): $\tilde{\nu}$ = 3570 (sharp, shoulder), 3450 (br., OH), 1604, 1574, 1481, 1444 (sharp, py), 1100 (vs, $ClO_4^-$) cm$^{-1}$.$C_{44}H_{52}Cl_2Cu_2N_6O_{12}$ (1054.9): calcd. C 50.1, H 5.0, N 8.0, Cu 12.0; found C 48.8, H 4.9, N 8.1, Cu 12.3.

**$[L^2Cu(\mu\text{-}OH)_2CuL^2](ClO_4)_2\cdot H_2O$ ($2\cdot H_2O$):** To a suspension of $[Cu(CH_3CN)_4](ClO_4)$ (654 mg, 2 mmol) in $CH_2Cl_2$ (10 mL) was added a dichloromethane solution of the ligand (607 mg, 2 mmol) under an atmosphere of nitrogen. The mixture was stirred for 30 min after which the flask was opened to the atmosphere. After several hours a blue solid separated. Recrystallization from boiling ethanol gave crystals suitable for X-ray diffraction studies. Yield: 460 mg (45%). IR (KBr pellet): $\tilde{\nu}$ = 3600 (sharp, shoulder), 3500 (br., OH), 1603, 1577, 1473, 1458 (sharp, py), 1100 (vs, $ClO_4^-$) cm$^{-1}$. $C_{40}H_{46}Cl_2Cu_2N_6O_{11}$ (1020.9): calcd. C 48.8, H 4.7, N 8.5, Cu 12.9; found C 48.2, H 4.6, N 8.5, Cu 13.4.

**$[L^3Cu(\mu\text{-}OH)_2CuL^3](ClO_4)_2$ (3):** To a suspension of $[Cu(CH_3CN)_4](ClO_4)$ (654 mg, 2 mmol) in $CH_2Cl_2$ (10 mL) was added a dichloromethane solution of the ligand (635 mg, 2 mmol) under an atmosphere of nitrogen. The mixture was stirred for 30 min after which the flask was opened to the atmosphere. Blue crystals of **3** suitable for X-ray studies were obtained by slow evaporation of the solvent. Yield: 448 mg (45%). IR (KBr pellet): $\tilde{\nu}$ = 3560 (sharp, shoulder), 3500 (br., OH), 1610, 1579, 1469, 1441 (sharp, py), 1095 (vs, $ClO_4^-$) cm$^{-1}$. $C_{42}H_{48}Cl_2Cu_2N_6O_{10}$ (994.9): calcd. C 50.7, H 4.9, N 8.5, Cu 12.8; found C 52.1; H 4.8; N 8.2; Cu 13.1.

**$[L^3Cu(\mu\text{-}OMe)_2CuL^3](ClO_4)_2$ (4):** This compound was obtained by recrystallization of compound **3** in boiling methanol. IR (KBr pellet): $\tilde{\nu}$ = 1609, 1578, 1468, 1441 (sharp, py), 1090 (vs, $ClO_4^-$) cm$^{-1}$. $C_{44}H_{52}Cl_2Cu_2N_6O_{10}$ (1022.9): calcd. C 51.6, H 5.1, N 8.2, Cu 12.4; found C 50.8, H 5.0, N 7.9, Cu 12.6.

**$[L^3Cu(\mu\text{-}F)_2CuL^3](BF_4)_2\cdot 2CH_2Cl_2$ ($5\cdot 2CH_2Cl_2$):** To a cooled (–20 °C) solution of $[L^3Cu(CH_3CN)]BF_4$ (89 mg, 0.175 mmol) in $CH_2Cl_2$ (5 mL) was added $O_2$-saturated $CH_2Cl_2$ solution (5 mL). The initially bright-yellow solution turned deep green spontaneously. The mixture was stirred for 1 h at –20 °C. Removal of the solvent gave a deep green residue that was recrystallized from $CH_2Cl_2$ at –10 °C to afford a green product. Yield: 30 mg (36%). $C_{44}H_{50}B_2Cl_4Cu_2F_{10}N_6$ (1143.42): calcd. C 47.68, H 4.69, N 8.20; found C 45.71, H 4.64, N 8.67.

**$[L^4Cu(\mu\text{-}Cl)_2CuL^4](ClO_4)_2$ (6):** This complex was obtained by the reaction of a 1:1 mixture of copper(II) perchlorate hexahydrate (370 mg) and anhydrous copper(II) chloride (135 mg) with the $L^4$ ligand in methanol. Recrystallization from boiling methanol afforded crystals suitable for X-ray diffraction. Yield: 442 mg (44%). IR (KBr pellet): $\tilde{\nu}$ = 1610, 1570, 1485, 1448 (sharp, py), 1100 (vs, $ClO_4^-$) cm$^{-1}$. $C_{40}H_{42}Cl_4Cu_2N_6O_8$ (1003.7): calcd. C 47.8, H 4.2, N 8.4, Cu 12.7; found C 47.1, H 4.0, N 8.3, Cu 12.5.

**$[Cu(\mu\text{-}L^5)_2Cu](ClO_4)_2$ (7):** Evaporation of the residual solution resulting from the synthesis of compound **3** gave a blue-green syrup that was dissolved in acetonitrile. Slow evaporation of this solution gave a small amount of green crystals identified as compound **7** by X-ray diffraction.

**X-ray Data Collection and Refinement Details:** Single crystals of the compounds were glued to the tip of glass capillaries and then

[a] $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$. $R_w = [\Sigma w(|F_o| - |F_c|)^2/\Sigma w(F_o)^2]^{1/2}$, where $w = 1/\sigma^2(F_o)$. $\lambda$(Mo-$K_\alpha$) = 0.71073 Å.

mounted on either a Bruker SMART-APEX[28a] (**1**–**4**, **6**, **7**), or a Bruker-Nonius Kappa CCD diffractometer [{$L^3$Cu(PPh$_3$)}(BF$_4$) and **5**]. Intensity data for **1**–**4**, **6**, and **7** were collected by using 10 s by frame (except for **4** where 30 s was used), separated by 0.3°. Data integration and cell refinement was made by using SAINTPLUS.[28b] The structures were solved by direct methods with the use of XS and XL in SHELXTL,[28c] or the program system SHELXL-97 in connection with absorption correction.[28d] Anisotropic thermal parameters were included for all non-hydrogen atoms. H atoms were placed geometrically and refined by using a riding model, including free rotation of methyl groups and variable isotropic displacement parameters. Final *R* values and important bond parameters are listed in Tables 1, 2, 5, and 6.

Analysis of the raw data for complex **3** clearly suggested that the crystal had two identifiable components, related by a 180° rotation around <–1,–2,0>. Data reduction using both components shows one major component (mean $I/\sigma$ = 2.0) and a minor one (mean $I/\sigma$ = 0.5). A rather small amount of reflections (≈5%) corresponds to overlapped data. Structure solution and structure refinement were finally performed considering just the major component.

During the last stages of refinement some disorder of the perchlorate anions for complexes **1**, **2**, **3**, **4**, and **6** was obvious. This was modeled by using partially occupied positions, which were first refined and then held constant for the final refinement.

**DFT Calculations:** DFT calculations were carried out by using the Amsterdam Density Functional package[29a] developed by Baerends and coworkers.[29b–29f] The local density approximation for electron correlation was treated with the Vosko–Wilk–Nusair parametrization.[30a] The nonlocal corrections of Becke[30b,30c] and Perdew[30d,30e] (BP86) were added to the exchange and correlation energies, respectively. The numerical integration procedure applied for the calculations was developed by te Velde et al.[29f] The standard ADF STO TZP basis set was used.[29a] The frozen-core approximation[30f] was considered for Cu, 3p; Cl, 2p; F, O, N, and C, 1s. Geometry optimization and single point calculations were done for $[Cu_2L_2X_2]^{2+}$ by considering a unrestricted singlet state involving $C_i$ or $C_2$ symmetry as constraints for *anti* and *syn* models, respectively.

CCDC-647370 to -647377 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see footnote on the first page of this article): Selected DFT optimized distances and angles for model complexes **1**–**6**, **8**, and $[L^2Cu(\mu\text{-MeO})_2CuL^2]^{2+}$, bond lengths and angles for [$L^3$Cu(PPh$_3$)](BF$_4$).

# Homo- and Heterometallic Coordination Oligomers and Polymers Derived from the Preformed Complexes $[Cu(bdmpp)(MeCN)_2](ClO_4)_2$, $[Cu(bdmpp)(N_3)_2]$, and $[Cu(bdmpp)(N_3)(\mu\text{-}N_3)]_2$ [bdmpp = 2,6-bis(3,5-dimethyl-1*H*-pyrazol-1-yl)pyridine]: Syntheses, Structures, and Redox Properties

**Guang-Fei Liu,[a] Zhi-Gang Ren,[a] Hong-Xi Li,[a] Yang Chen,[a] Qiu-Hong Li,[a] Yong Zhang,[a] and Jian-Ping Lang*[a,b]**

**Keywords:** Copper / Structures / Oligomers / Polymers / Redox properties

Reactions of three $Cu^{II}$ complexes of 2,6-bis(3,5-dimethyl-1*H*-pyrazol-1-yl)pyridine (bdmpp), $[Cu(bdmpp)(MeCN)_2](ClO_4)_2$ (**1**), $[Cu(bdmpp)(N_3)_2]\cdot 1.5H_2O$ (**2**·$1.5H_2O$), and $[Cu(bdmpp)(N_3)(\mu\text{-}N_3)]_2\cdot 2MeOH$ (**3**·2MeOH), with 4,4′-bipy, dicyanamide (dca), azide, and $MCl_2$ (M = Cu, Co, Ni) yield a series of homo- and heterometallic coordination oligomers and polymers, $[\{Cu(bdmpp)(ClO_4)\}_2(\mu\text{-}4,4'\text{-bipy})](ClO_4)_2$ (**4**), $\{[Cu(bdmpp)(\mu\text{-dca})](ClO_4)\}_n$ (**5**), $\{[Cu(bdmpp)(\mu\text{-}N_3)](ClO_4)\cdot MeCN\}_n$ (**6**), $[\{Cu(N_3)(bdmpp)\}_2(\mu\text{-}N_3)_2Cu(N_3)_2]$ (**7**), and $[\{Cu(\mu\text{-}N_3)(bdmpp)(\mu\text{-}N_3)M(\mu\text{-}N_3)(X)\}_2\cdot eMeCN]_n$ (**8**: M = Co, X = $N_3$, *e* = 0; **9**: M = Ni, X = Cl; *e* = 4). Compounds **1**–**9** have been characterized by elemental analysis, IR spectroscopy, and single-crystal X-ray crystallography. Compound **4** has a centrosymmetric dimeric dication structure in which two $[Cu(bdmpp)(ClO_4)]^+$ fragments are bridged by one 4,4′-bipy. Compounds **5** and **6** have a 1D linear or spiral chain extending along the *b* axis in which each $[Cu(bdmpp)]^{2+}$ fragment is linked through bridging dca or azide anions, respectively. Compound **7** has a trinuclear sandwich structure in which two molecules of **2** link a $Cu(N_3)_2$ species through two end-on bridging azide anions. Compounds **8** and **9** have a similar 1D chain structure extending along the *c* axis in which $[Cu(\mu\text{-}N_3)(bdmpp)(\mu\text{-}N_3)M(\mu\text{-}N_3)(X)]_2$ (M = Co, Ni) molecules are linked by end-to-end azide anions (**8**) or end-on azide anions (**9**). In addition, the electrochemical properties of **1**–**9** in DMF were investigated by cyclic voltammetry. (© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2007)

## Introduction

In past decades, design and construction of coordination oligomers and polymers from metal complex or cluster precursors has attracted considerable attention because of their structural diversity[1–11] and their potential applications in advanced materials.[12–20] From the viewpoint of the "design", a suitable metal complex or cluster precursor may possess one of the following requirements. Firstly, that some ligands around the metal center or cluster core are labile and readily replaced by other strong donor ligands. Secondly, that some ligands in the complex or cluster are potential multilinkers to interconnect with other metal centers or cluster cores. Thirdly, that the coordination is unsaturated for at least one metal atom of the complex or cluster. Many preformed clusters match these requirements and have been employed to serve as excellent precursors for the formation of a number of cluster-based supramolecules.[3–6,8–11,21–24] In contrast to the cluster precursors, employment of the preformed metal complexes for the formation of homo- or heterometallic coordination oligomers or polymers is less explored.

Recently we have been engaged in the construction of coordination oligomers and polymers from preformed mononuclear complexes and metal sulfide clusters.[11,21–26] One useful approach is to introduce the bulky ligands that block some of the coordination sites of the metal center, which may cause it to form the unsaturated coordination geometry. Among numerous bulky ligands, the tridentate ligand 2,6-bis(3,5-dimethyl-1*H*-pyrazol-1-yl)pyridine (bdmpp) attracted our attention. This ligand has been employed to react with metal ions to form various complexes.[27–30] Some metal/bdmpp complexes did show unsaturated coordination geometry around the metal center.[27–30] However, these compounds have not been used as precursors to further assemble coordination oligomers and polymers. To this end, we prepared three $Cu^{II}$/bdmpp complexes, $[Cu(bdmpp)(MeCN)_2](ClO_4)_2$ (**1**), $[Cu(bdmpp)(N_3)_2]\cdot 1.5H_2O$ (**2**·$1.5H_2O$), and $[Cu(bdmpp)(N_3)(\mu\text{-}N_3)]_2\cdot 2MeOH$ (**3**·2MeOH), in high yields. Compounds **1**–**3** match the above-mentioned requirements and could be used as pre-

cursors to form a family of homo- and heterometallic coordination oligomers and polymers: $[\{Cu(bdmpp)(ClO_4)\}_2(\mu\text{-}4,4'\text{-bipy})](ClO_4)_2$ (**4**), $\{[Cu(bdmpp)(\mu\text{-dca})](ClO_4)\}_n$ (**5**), $\{[Cu(bdmpp)(\mu\text{-}N_3)](ClO_4)\cdot MeCN\}_n$ (**6**), $[\{Cu(N_3)(bdmpp)\}_2(\mu\text{-}N_3)_2Cu(N_3)_2]$ (**7**), and $[\{Cu(\mu\text{-}N_3)(bdmpp)(\mu\text{-}N_3)M(\mu\text{-}N_3)(X)\}_2\cdot e MeCN]_n$ (**8**: M = Co, X = $N_3$, $e$ = 0; **9**: M = Ni, X = Cl; $e$ = 4). Furthermore, we have employed cyclic voltammetry (CV) to investigate the electrochemical behaviors of **1**–**9** in order to understand the changes of the redox properties of the assembled oligomers and polymers relative to their precursors. In this paper, we report their syntheses, crystal structures, and redox properties.

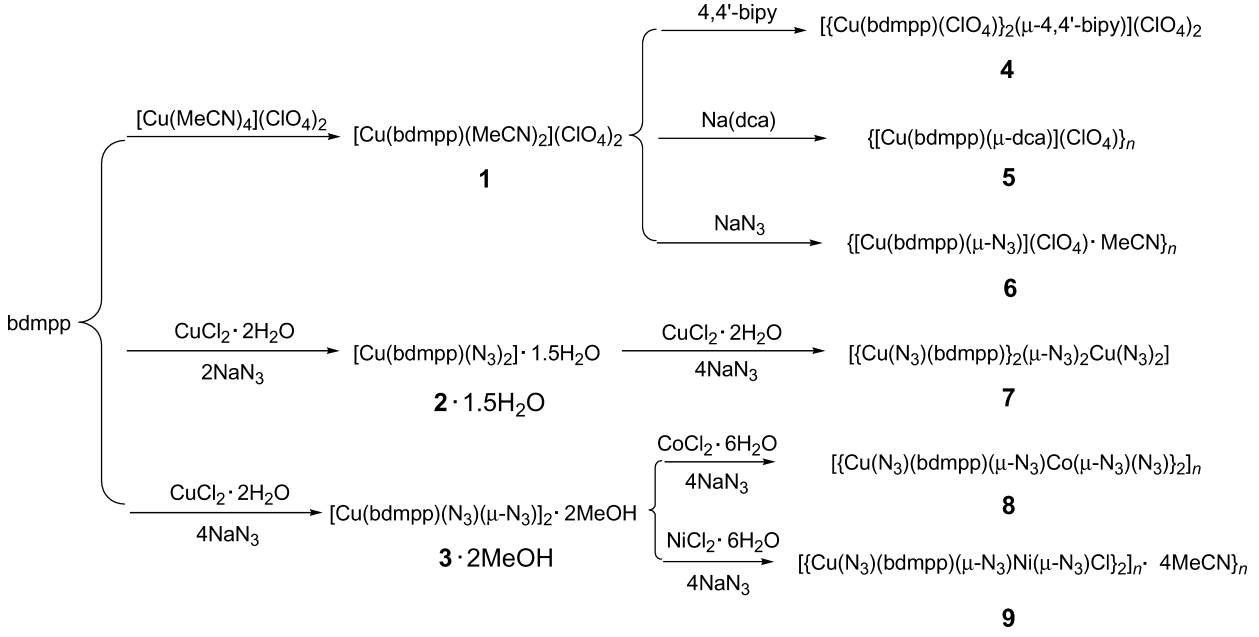
## Results and Discussion

Reaction of $[Cu(MeCN)_4](ClO_4)_2$ with equimolar bdmpp in MeCN resulted in a green solution. Slow diffusion of $Et_2O$ into the solution led to the formation of green blocks of **1** in 85% yield (Scheme 1). On the other hand, treatment of $CuCl_2\cdot 2H_2O$ with $NaN_3$ and bdmpp in 1:2:1 and 1:4:1 (molar ratio) in MeOH followed by slow evaporation of solvents gave rise to **2**·1.5$H_2O$ and **3**·2MeOH in 75% and 72% yields, respectively. The formation of **2**·1.5$H_2O$ and **3**·2MeOH depended on the molar ratio of $CuCl_2\cdot 2H_2O$ and $NaN_3$ during the reaction. As discussed later in this paper, when the lower ratio (1:2) was used, the Cu atom was apt to adopt a less saturated coordination (five-coordinate) and **2**·1.5$H_2O$ was thus formed. When the higher ratio (1:4 or more) was used, the Cu atom was more apt to adopt a saturated coordination (six-coordinate) and **3**·2MeOH was formed.

As discussed later in this paper, the $Cu^{II}$ atom in **1** is chelated by one bdmpp and coordinated by two labile MeCN molecules. When the two MeCN molecules are replaced by strong bridging donor ligands, the $Cu^{II}$ center may have up to three more coordination sites available and its trigonal-bipyramidal coordination geometry may be turned to square-planar, square-pyramidal, or octahedral. The remaining $[Cu(bdmpp)]^{2+}$ fragment along with bridging ligands may serve as multiconnecting nodes to form novel oligomers and polymers. Among the potential bridging donor ligands, we chose 4,4′-bypyridine (4,4′-bipy), sodium dicyanamide, and sodium azide for this purpose.

Treatment of **1** with equimolar 4,4′-bipy followed by a similar procedure used in the isolation of **1** produced blue crystals of **4** in 63% yield, while reactions of **1** with equimolar sodium dicyanamide or sodium azide followed by a similar workup gave rise to green crystals of **5** and deep green crystals of **6** in 75% and 80% yields, respectively (Scheme 1). It is noted that in these cases, the two MeCN molecules coordinated at the Cu center of **1** were replaced and the $[Cu(bdmpp)]^{2+}$ fragment was retained, even though the coordination geometry of the Cu atom was changed during the reactions. The different outcomes from the aforementioned three reactions deserve comment. Compared with the dca and $N_3^-$ ligands, 4,4′-bipy seems somewhat bulky and rigid. The replacement of the two MeCN molecules of the cation of **1** by 4,4′-bipy only afforded a dinuclear complex **4**. The less rigid ligand, dca or $N_3^-$, removed the two MeCN molecules of the cation of **1** and linked the $[Cu(bdmpp)]^{2+}$ fragments through end-to-end μ-1,5-bridging mode (dca) or μ-1,3-bridging mode ($N_3^-$), forming polymeric species **5** and **6**, respectively.

In the cases of **2** and **3**, both complexes may also work as precursors for oligomers and polymers as they have two terminal azides that could link other metal ions. Accordingly, reactions of **2** with a mixture of $CuCl_2\cdot 2H_2O$ and $NaN_3$ in a molar ratio of 1:1:4 produced the homometallic



Scheme 1. Reactions of bdmpp with $[Cu(MeCN)_4](ClO_4)_2$ and $CuCl_2\cdot 2H_2O/NaN_3$; reactions of **1** with 4,4′-bipy, Na(dca), and $NaN_3$; reactions of **2** with $CuCl_2\cdot 2H_2O$ and $NaN_3$; and reactions of **3** with $MCl_2\cdot 6H_2O$ (M = Cu, Co, Ni) and $NaN_3$.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

oligomer **7** in 67% yield, while those of **3** with a mixture of $MCl_2·6H_2O$ (M = Co, Ni) and $NaN_3$ in a molar ratio of 1:1:4 followed by a similar workup afforded two heterometallic polymers, **8** and **9**, in 50% and 49% yields, respectively (Scheme 1). In these cases, **2** or **3** only used their terminal azides to link the possible $Cu(N_3)_2$ or $[M(\mu\text{-}N_3)(X)]_2$ (M = Co, X = $N_3$; M = Ni, X = Cl) species. The coordination geometry for each Cu center in **2** or **3** is retained.

Solids **1**–**9** were relatively air- and moisture-stable, and were soluble in DMF and DMSO. The elemental analysis was consistent with the chemical formula of **1**–**9**. The IR spectrum of **1** showed a sharp $\nu$(CN) at 2249 $cm^{-1}$, suggesting the presence of terminal acetonitrile molecules. In the IR spectra of **2**·1.5$H_2O$, **3**·2MeOH, and **6**–**9** the strong absorptions at 2040/2068 (**2**·1.5$H_2O$), 2045 (**3**·2MeOH), 2041 (**7**), and 2029 (**8**) $cm^{-1}$ may be attributed to the asymmetric stretching frequencies of the terminal azide groups while those at 2073 (**3**·2MeOH), 2054/2066 (**6**), 2066 (**7**), 2066 (**8**), and 2069 (**9**) $cm^{-1}$ may be assigned to be the asymmetric stretching vibrations of end-on or end-to-end bridging azide groups.[31] In the IR spectrum of **5**, a band at 2179 $cm^{-1}$ was assigned to be the stretching vibration of the dca ligand with a bidentate $\mu_{1,5}$ coordination.[25] In the IR spectra of **1** and **4**–**6**, strong and broad peaks at 1122/1087/1060 (**1**), 1093/1024 (**5**), and 1144/1118/1084 (**6**) $cm^{-1}$ are the characteristic Cl–O stretching vibrations of the free perchlorate anions while that at 1087 $cm^{-1}$ (**4**) may be assigned to be a unidentate perchlorato ligand. The identities of **1**–**9** were further confirmed by X-ray crystallography.

Compound **1** crystallizes in the orthorhombic space group *Pbca* and the asymmetric unit consists of one $[Cu(bdmpp)(MeCN)_2]^{2+}$ dication and two $ClO_4^-$ anions. Unlike the most reported fashion of the square-pyramidal geometry,[30] the five-coordinate copper(II) atom in **1** adopts a distorted trigonal-bipyramidal geometry, which is coordinated by three N atoms from the bdmpp ligand and two N atoms from the acetonitrile molecules (Figure 1). N(1) and N(5) are located in apical positions, while N(3),

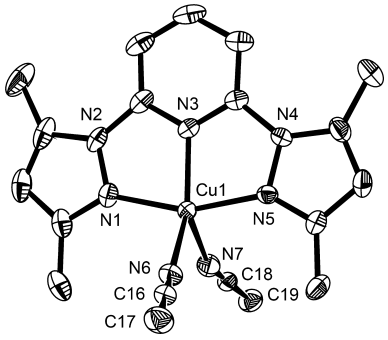


Figure 1. Perspective view of the $[Cu(bdmpp)(MeCN)_2]^{2+}$ dication of **1** with 50% thermal ellipsoids. All hydrogen atoms are omitted for clarity.

N(6), and N(7) are in equatorial positions. The two Cu–N (MeCN) bonds are longer than the three Cu–N (bdmpp) bonds (Table 1), suggesting that the two MeCN molecules may be easily replaced by other strong donor ligands.

Compounds **2**·1.5$H_2O$ and **3**·2MeOH crystallize in the monoclinic space group $P2_1/n$ and the asymmetric unit of **2** contains one discrete [Cu(bdmpp)$(N_3)_2$] molecule and one and a half of the water solvent molecules, while that of **3** has half of the [Cu(bdmpp)(μ-$N_3$)$(N_3)$]$_2$ molecule and one methanol solvent molecule. In the structure of **2**, Cu(1) adopts a distorted square-pyramidal geometry (Figure 2). The basal plane is defined by N(1), N(3), and N(5) from the bdmpp ligand and N(6) from a terminal azide. The apical site is occupied by N(9) of the other terminal azide. The axial Cu(1)–N(9) of 2.186(2) Å is slightly longer than the basal Cu–N bonds (Table 1), but shorter than that found in [$Cu_2$(terpy)$_2$-μ-$(N_3)_2(N_3)_2Cu_3$-μ-$(N_3)_4(N_3)_2$] [terpy = 2,2′:6′,2′′-terpyridine, 2.288(3) Å].[20] It is noted that Cu(1) displaces 0.3613 Å out of the N(1)–N(3)–N(5)–N(6) least-squares plane, which causes the *trans* angles in the basal plane to deviate significantly from 180°.

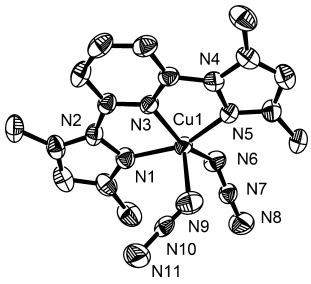

Figure 2. Molecular structure of **2** with 50% thermal ellipsoids. All hydrogen atoms are omitted for clarity.

As shown in Figure 3, **3** consists of two [Cu(bdmpp)-$(N_3)$]$^+$ fragments that are bridged by a pair of end-on bridging $N_3^-$ anions, forming a centrosymmetric dimetallocyclic $Cu_2N_2$ core structure. The $Cu_2N_2$ core is symmetric and the Cu(1)···Cu(1A) contact is 3.263(13) Å, which excludes any metal–metal interaction. Each Cu atom adopts a distorted octahedral geometry, where N(1), N(3), and N(5) of the bdmpp ligand and N(6) of the bridge azide occupy the equatorial sites, and N(6A) and N(9) from one bridging and one terminal azide sit at the two apical sites. The Cu atom lies 0.1024 Å out of the equatorial plane. The average Cu–$N_{apical}$ bond [2.128(4) Å] is slightly longer than the average Cu–$N_{equatorial}$ bond [2.075(4) Å] (Table 1).

Compound **4** crystallizes in the triclinic space group $P\bar{1}$ and the asymmetric unit contains half of the [{Cu(bdmpp)$(ClO_4)$}$_2$(μ-4,4′-bipy)]$^{2+}$ dication and one $ClO_4^-$ anion. The centrosymmetric structure of the dication contains two [Cu(bdmpp)$(ClO_4)$]$^+$ fragments bridged by one 4,4′-bipy ligand (Figure 4). As indicated in Table 2, Cu(1) in each [Cu(bdmpp)$(ClO_4)$]$^+$ fragment takes a distorted square-pyramidal geometry, coordinated by N(1), N(3), and N(5) from the bdmpp ligand and N(6) from 4,4′-bipy, which are in equatorial positions, and O(1) from one

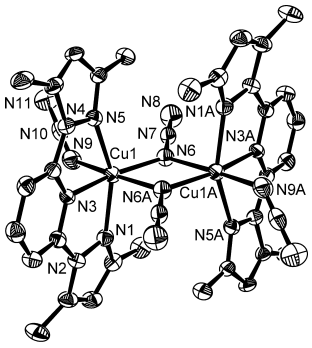

Figure 3. Molecular structure of **3** with 50% thermal ellipsoids. All hydrogen atoms are omitted for clarity.

$ClO_4^-$, which occupies the apical site. Cu(1) sits over the basal plane with out-of-plane displacement of 0.1688 Å. The Cu(1)–N bond lengths are similar to those of **2**, while the Cu(1)–O bond length [2.2856(18) Å] is comparable to that observed in complexes containing square-pyramidally coordinated $Cu^{II}$ [Cu(pr2pz)$(ClO_4)_2$] [pr2pz = 1,2-bis[5-methyl-3-(2-methylpropyl)amino-1*H*-pyrazol-1-yl]ethane, 2.451(3) Å].[32]

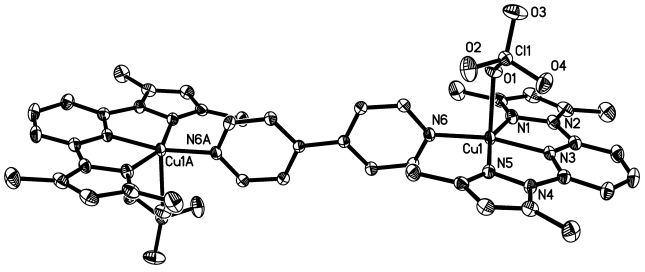

Figure 4. Perspective view of the [{Cu(bdmpp)$(ClO_4)$}$_2$(μ-4,4′-bipy)]$^{2+}$ dication of **4** with 50% thermal ellipsoids. All hydrogen atoms are omitted for clarity.

Compound **5** crystallizes in the monoclinic space group $C2/c$ and the asymmetric unit consists of one [Cu(bdmpp)(μ-dca)]$^+$ cation and one $ClO_4^-$ anion. Like that of the Cu center of **1**, Cu(1) in the cation of **5** adopts a distorted trigonal-bipyramidal geometry, coordinated by N(3) of the bdmpp ligand and N(6) and N(8A) atoms of μ-dca (in equatorial positions), and N(1) and N(5) of the bdmpp ligand (in apical positions) (Figure 5). The bond lengths and angles around Cu(1) in **5** (Table 2) are similar to those observed in **1**. Topologically, the [Cu(bdmpp)]$^{2+}$ fragment in **5** works as a two-connecting node, which is linked to two equivalent nodes through Cu-μ-dca-Cu bridges to form a 1D [Cu(bdmpp)(μ-dca)]$_n^{n+}$ chain extending along the *b* axis. It is worth noting that the bdmpp ligands covering the chain are parallel to each other and have the same direction. Two neighboring bdmpp ligands linked by one dca may be visualized as a molecular clip with a diameter of 7.4952(3) Å [Cu(1)···Cu(1A) contact]. Thus, the structure of **5** may be best described as a unique 1D chain of clips, each of which "clamps" one $ClO_4^-$ anion inside it.

[a] Symmetry codes for **5**: A: $x$, $y - 1$, $z$; for **6**: A: $-x + 1/2$, $y - 1/2$, $-z + 1/2$.

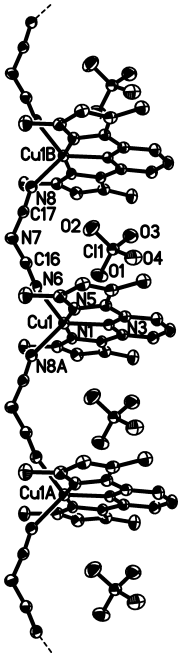

Figure 5. View of a section of the chain of **5** (extending along the *b* axis) with 50% thermal ellipsoids. All hydrogen atoms are omitted for clarity.

Compound **6** crystallizes in the monoclinic space group $P2_1/n$, and the asymmetric unit consists of one $[Cu(bdmpp)(\mu\text{-}N_3)]^+$ cation, one $ClO_4^-$ anion, and one MeCN solvent molecule. The $[Cu(bdmpp)]^{2+}$ fragment of **6** again acts as a two-connecting node, which is connected to the equivalent nodes through end-to-end bridging $N_3^-$ to form a 1D spiral chain extending along the *b* axis (Figure 6). The average chain-to-chain separation is 3.9 Å, and there are no evident interactions between the cationic chains and the counteranions and MeCN solvent molecules. For the $[Cu(bdmpp)(\mu\text{-}N_3)]^+$ cation of **6**, the Cu(1) atom adopts a similar coordination geometry to that of **2**, coordinated by N(1), N(3), and N(5) of the bdmpp ligand, and N(6) of one azide anion (in equatorial sites) and N(8A) of the other azide anion (in apical site). As listed in Table 2, one end-to-end bridging Cu(1)–N(8A) bond [2.448(2) Å] is 0.5 Å longer than the other one [Cu(1)–N(6)], which may be due to the requirement for the formation of the spiral chain. Other bond lengths and angles around Cu(1) in **6** are comparable to those of the corresponding ones of **2**.

Compound **7** crystallizes in the triclinic space group $P\bar{1}$ and the asymmetric unit contains half of the $[\{Cu(bdmpp)(N_3)\}_2(\mu\text{-}N_3)_2Cu(N_3)_2]$ molecule. The molecular structure of **7** is shown in Figure 7 and the selected bond lengths and angles are listed in Table 3. In this structure, the framework of **2** is almost retained. Two molecules of **2** link a $Cu(N_3)_2$ species through two end-on bridging azide anions to form a sandwich structure. Alternatively, the structure may be viewed as a centrosymmetric sandwich structure, in which one planar $[Cu(N_3)_2(\mu\text{-}N_3)_2]^{2-}$ anion is placed in between two planar $[Cu(bdmpp)(N_3)]^+$ cations through a pair of Cu-μ-$N_3$-Cu bridges. The skeleton planes of the two bdmpp ligands are almost parallel but with opposite orientations, and their separation is about 6.3 Å. In

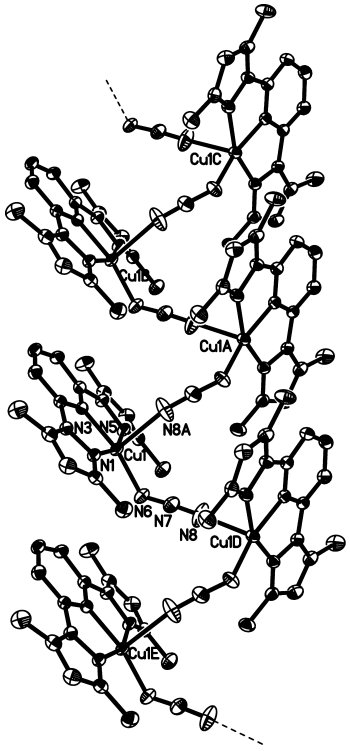

Figure 6. View of a section of the chain of **6** (extending along the *b* axis) with 50% thermal ellipsoids. All hydrogen atoms are omitted for clarity.

the $[Cu(bdmpp)(N_3)]^+$ cations, Cu(1) or Cu(1A) has a square-pyramidal geometry. The Cu(1)–N (bdmpp) and Cu(1)–N (terminal $N_3^-$) bond lengths are similar to those of **2**. The end-on bridging Cu(1)–N(9) bond is slightly longer than the corresponding bond of **2** and shorter than that of **6**. For the $[Cu(N_3)_2(\mu\text{-}N_3)_2]^{2-}$ anion, Cu(2) has a typical square-planar geometry, coordinated by two terminal and two end-on bridging azide anions. The bridging Cu(2)–N(9) bond [2.343(2) Å] is 0.38 Å longer than the terminal Cu(2)–N(12) bond.

Compounds **8** and **9** crystallize in the triclinic space group $P\bar{1}$ and the asymmetric unit contains half of the $[Cu(\mu\text{-}N_3)(bdmpp)(\mu\text{-}N_3)M(\mu\text{-}N_3)(X)]_2$ molecule (**8**: M = Co, X = $N_3$; **9**: M = Ni, X = Cl) and two MeCN solvent molecules for **9**. Compounds **8** and **9** have a 1D chain structure (extending along the *c* axis) in which $[Cu(\mu\text{-}N_3)(bdmpp)(\mu\text{-}N_3)M(\mu\text{-}N_3)(X)]_2$ molecules are linked by

end-to-end azide anions (**8**) (Figure 8, left) or end-on azide anions (**9**) (Figure 8, right). Each $[Cu(\mu\text{-}N_3)(bdmpp)(\mu\text{-}N_3)\text{-}M(\mu\text{-}N_3)(X)]_2$ molecule consists of one centrosymmetric $[Cu(bdmpp)(\mu\text{-}N_3)]_2^{2+}$ dication and one centrosymmetric $[(\mu\text{-}N_3)M(\mu\text{-}N_3)(X)]_2^{2-}$ dianion linked by one end-to-end azide (**8**) or one end-on azide (**9**). The structure of the dication in **3** is almost kept in the structures of **8** and **9**. Each Cu atom in **8** or **9** adopts a distorted octahedral geometry, coordinated by three N atoms from one bdmpp ligand and three N atoms from one end-to-end and two end-on azides (**8**) or three end-on azides (**9**). In this case, the end-to-end bridging Cu(1)–N(9) bond of **8** is even shorter than the end-on bridging Cu(1)–N(9) in **9** (Table 4). Other bond lengths and angles around Cu in **8** or **9** are similar to those of the corresponding ones of **3**. The Cu(1)···Cu(1A) separation is 3.2105(14) Å for **8** and 3.3779(13) Å for **9**.

Within the dianion of **8**, each Co atom is coordinated by one terminal, one end-to-end bridging, and two bridging azides, forming a square-planar geometry. The Co(1)···Co(1B) contact is 3.1234(13) Å while the Cu(1)···Co(1) contact between the dication and dianion is 4.4064(13) Å. The mean Co(1)–N bond length [1.966(4) Å] is similar to that found in $[PPh_4][Co(N_3)_3Cl]$[33] [Co–N 1.946(3) Å]. However, in the structure of the anion of **9**, each Ni atom also adopts a square-planar geometry, coordinated by one terminal Cl atom and three end-on bridging azides. The Ni(1)···Ni(1B) contact is 3.091(2) Å while the Cu(1)···Ni(1) contact between the dication and dianion is 3.5670(12) Å. The terminal Ni(1)–Cl(1) bond [2.2499(19) Å] is longer than that found in [(L)NiKCl·3THF] [L = *N*,*N*′-bis(2,6-diisopropylphenyl)-2,6-pyridinedicarboxamido, 2.1688(17) Å],[34] while the Ni–N bond is slightly longer than that in $[L^1Ni(N_3)]$ [$L^1$ = $Me_2NCH_2CH_2N(Me)C_6H_4OH$, 1.905(7) Å].[35]

The electrochemical behaviors of **1**–**9** have been investigated by cyclic voltammetry (CV) in DMF containing 0.1 M tetraethylammonium perchlorate (TEAP). The electrochemical data are summarized in Table 5. Under similar experimental conditions, the electrochemical studies of the free ligand using the cyclic voltammetry showed no electrochemical activity within the scanned potential window. Thus, the electrochemical waves observed in the cyclic voltammograms of **1**–**9** are only metal-based.

All the complexes show the quasireversible redox process with a potential of about 0.00 V in the cathode and about

[a] Measured by CV at scan rate of 0.1 V/s; 1.0 mM in DMF containing 0.1 M TEAP for all complexes with a concentration of $1 \times 10^{-3}$ M. Condition: working electrode, Pt plate ($2 \times 2$ mm$^2$); counter electrode, Pt wire; reference electrode, SCE.

0.22 V in the anode (except 0.33 V for **3**, 0.56 V for **7**, and 0.59 V for **9**) (Figure 9), corresponding to the change from $Cu^{II}$ species to $Cu^{I}$ species. When the CV measurements were performed at different scan rates such as 0.05, 0.1, 0.2, and 0.5 V/s, it was found that the ratio of cathodic to anodic peak current was close to unity, especially for a lower scan rate, suggesting this first step is a quasireversible reduction process.[36] The second reduction waves in the range of –0.40 to –0.70 V for **1**, **4**, **5**, **7**, **8**, and **9** are quasireversible and due to the formation of $Cu^{I}$ species followed by the deposition of $Cu^0$ onto the electrode surface as judged by the appearance on the reverse scan of a greater anodic peak current at the corresponding potential $E_{II}'$ than that of the cathode.[37] The separation between the potentials of the first redox couple for all complexes is $\Delta E_I$ = 0.15 V or greater and the weak peak current at $E_{II}$ indicates that a geometrical reorganization, hindered to a large extent by the low flexibility of the coordination sphere, is involved in the reduction process.[36] After several cycles, the color of solutions of these complexes became light and more metal particles were found on the electrode surface. These facts were the evidence of the decomposition of the complexes during the CV measurement.

Compared to the second reduction wave of their precursor **1**, those of **4** and **6** are very weak and the potential shift negative (Figure 9a), while the second reduction electrochemical response and potential of **5** are almost the same as **1**. These facts indicate that the stronger binding of azide and 4,4′-bipy ligands to the metal center and the coordination sphere is more stable than that of dca and acetonitrile ligands.

The large difference of $\Delta E_I$ value (0.55 V for **7** and 0.61 V for **9**) between the the potentials of the first redox couple is consistent with the stronger spin–spin interaction of metals. Further reductions at $E_{III}$ = –1.26 V for **7**, –1.28 V for **8**, and –1.03 V for **9** are almost totally irreversible, which may be due to the deposition of $Cu^0$ (planar Cu), $Co^0$, and $Ni^0$ onto the electrode surface as judged by the appearance of a sharp anodic peak at $E_{III}'$ = 0.18, 0.02, and –0.12 V for **7**, **8**, and **9**, corresponding to the redissolution of $Cu^0$, $Co^0$, and $Ni^0$, respectively.

## Conclusions

In this paper, we demonstrated our new approaches to the assembly of a set of homometallic or heterometallic coordination oligomers and polymers from reactions of preformed complexes **1**–**3** with different linkers 4,4′-bipy, dca, and azide as well as $M^{2+}$ (M = Cu, Co, Ni). In the structures of **4**–**6**, the $[Cu(bdmpp)]^{2+}$ fragment of **1** was retained, even though the copper coordination geometry was changed during the reactions. Compound **4** forms a 4,4′-bipy-bridged dimer structure, while **5** and **6** show a 1D dca-bridged chain of clips and a 1D spiral azido-bridged chain, respectively. In this structure of **7**, the structure of **2** was kept and two molecules of **2** connect a $Cu(N_3)_2$ species through two end-on bridging azide anions to form a sandwich structure. In the structure of **8** or **9**, the structure of **3** was retained, and the $[Cu(bdmpp)(\mu\text{-}N_3)(\mu\text{-}N_3)]_2$ molecules of **3** interconnect with the $[M(\mu\text{-}N_3)(X)]_2$ molecules through end-to-end azides (**8**) or end-on azides (**9**) to form a 1D chain structure. Electrochemical studies on **1**–**9** revealed that one quasireversible redox wave was observed at higher potential for all these complexes, while, **1**, **4**, **5**, **7**, **8**, and **9** showed the second quasireversible redox wave at lower potentials. It is concluded that though the assembled products retain the $[Cu(bdmpp)]^{2+}$ fragment of **1** or the whole molecule **2** or **3**, their electrochemical properties are influenced by the bridging ligands around the Cu center of the fragment or other metal ions introduced in their frameworks. The interesting topological structures of **4**–**9** make **1**–**3** very promising precursors for the synthesis of homo- and heterometallic coordination oligomers and polymers. We are currently extending this work by studies on the synthesis of novel homo- or heterometallic coordination oligomers and polymers from reactions of **1**–**3** with other polydentate donor ligands such as 5,10,15,20-tetra(4-pyridyl)-21*H*,23*H*-porphyrin and 2,4,6-tri(4-pyridyl)-1,3,5-triazine, and other main group metals ($Pb^{2+}$, $Bi^{3+}$) and transition metals ($Zn^{2+}$, $Cd^{2+}$, $Hg^{2+}$, etc.).

## Experimental Section

**General Remarks:** Compounds bdmpp[38] and $[Cu(MeCN)_4](ClO_4)_2$[39] were prepared according to the literature method. All other reagents were used as purchased. The IR spectra were recorded with a Varian 1000 FTIR spectrometer as KBr disk (4000–400 $cm^{-1}$). The elemental analyses for C, H, and N were performed on an EA1110 CHNS elemental analyzer. Cyclic voltammetry was carried out at 0.1 V/s under oxygen-free conditions using a three-electrode cell with platinum film electrode as working electrode, platinum wire as counter electrode, and SCE as reference electrode. In DMF solution, tetraethylammonium perchlorate (TEAP) was used as the supporting electrolyte.

**$[Cu(bdmpp)(MeCN)_2](ClO_4)_2$ (1):** bdmpp (0.027 g, 0.1 mmol) was added to a blue solution containing $[Cu(MeCN)_4](ClO_4)_2$ (0.043 g, 0.1 mmol) in MeCN (10 mL). The resulting green solution was stirred for about 0.5 h and then filtered. Diethyl ether (20 mL) was layered onto the filtrate to form green blocks of **1** (0.052 g, 85% based on bdmpp) in several days. IR (KBr disc): $\tilde{\nu}$ = 3137 (m), 2249 (m), 1614 (s), 1566 (s), 1486 (s), 1392 (s), 1320 (s), 1295 (s), 1144 (s), 1106 (s), 1059 (s), 995 (s), 795 (m), 743 (m), 622 (s) $cm^{-1}$. $C_{19}H_{23}Cl_2CuN_7O_8$ (611.88): calcd. C 37.30, H 3.79, N 16.02; found C 37.46, H 3.56, N 15.90.

**$[Cu(bdmpp)(N_3)_2]\cdot 1.5H_2O$ ($2\cdot 1.5H_2O$):** $NaN_3$ (0.013 g, 0.2 mmol) was added to a blue solution containing $CuCl_2\cdot 2H_2O$ (0.017 g, 0.1 mmol) in MeOH (5 mL) and $H_2O$ (5 mL). The solution turned deep brown instantly and bdmpp (0.027 g, 0.1 mmol) was added. The resulting deep green solution was stirred for about 0.5 h and then filtered. Slow evaporation of solvents from the solution for 2 weeks produced deep green crystals of $\mathbf{2}\cdot 1.5H_2O$ (0.033 g, 75% based on bdmpp). IR (KBr disc): $\tilde{\nu}$ = 3144 (w), 2924 (w), 2068 (vs), 2040 (vs), 1614 (vs), 1562 (s), 1488 (vs), 1418 (s), 1392 (s), 1319 (s), 1139 (m), 1054 (m), 986 (m), 799 (m), 740 (m), 675 (w) $cm^{-1}$. $C_{15}H_{20}CuN_{11}O_{1.5}$ (441.94): calcd. C 40.77, H 4.56, N 34.86; found C 40.46, H 4.42, N 34.91.

**$[Cu(bdmpp)(N_3)(\mu\text{-}N_3)]_2\cdot 2MeOH$ ($3\cdot 2MeOH$):** Compound $\mathbf{3}\cdot 2MeOH$ (0.032 g, 72% based on bdmpp) was isolated as deep green crystals from the reaction of $CuCl_2\cdot 2H_2O$ (0.017 g, 0.1 mmol), $NaN_3$ (0.026 g, 0.4 mmol), and bdmpp (0.027 g, 0.1 mmol) in $MeOH/H_2O$ followed by a similar workup to that used in the isolation of **2**. IR (KBr disc): $\tilde{\nu}$ = 3129 (w), 2073 (vs), 2045 (vs), 1614 (s), 1564 (m), 1487 (s), 1389 (m), 1318 (m), 1294 (m), 1141 (w), 1084 (w), 1054 (m), 848 (m), 791 (w), 742 (w), 558 (w) $cm^{-1}$. $C_{32}H_{42}Cu_2N_{22}O_2$ (893.98): calcd. C 43.00, H 4.74, N 34.47; found C 43.16, H 4.52, N 34.52.

**$[\{Cu(bdmpp)(ClO_4)\}_2(\mu\text{-}4,4'\text{-bipy})](ClO_4)_2$ (4):** 4,4′-bpy (0.016 g, 0.1 mmol) was added to a green solution containing **1** (0.061 g, 0.1 mmol) in MeCN (10 mL). The mixture was stirred for 10 min, the color of the solution then turned blue, and the solution was filtered. Layering $Et_2O$ (15 mL) onto the filtrate afforded blue blocks of **4** (0.038 g, 63% based on **1**). IR (KBr disc): $\tilde{\nu}$ = 3135 (w), 2996 (w), 1617 (s), 1594 (m), 1564 (m), 1486 (s), 1432 (m), 1390 (m), 1322 (m), 1122 (m), 1087 (s), 1060 (s), 992 (m), 790 (w), 744 (w), 624 (m) $cm^{-1}$. $C_{40}H_{42}Cl_4Cu_2N_{12}O_{16}$ (1215.76): calcd. C 39.51, H 3.48, N 13.82; found C 40.02, H 3.42, N 13.94.

**$\{[Cu(bdmpp)(\mu\text{-dca})](ClO_4)\}_n$ (5):** Compound **5** (0.037 g, 75% based on **1**) was isolated as green crystals from the reaction of **1** (0.061 g, 0.1 mmol) and Na(dca) (0.009 g, 0.1 mmol) followed by a similar workup to that used in the isolation of $\mathbf{2}\cdot 1.5H_2O$. IR (KBr disc): $\tilde{\nu}$ = 3130 (w), 2964 (m), 2179 (s), 1618 (s), 1566 (m), 1488 (s), 1370 (m), 1320 (m), 1261 (s), 1093 (s), 1024 (s), 800 (s), 744 (w), 624 (m) $cm^{-1}$. $C_{17}H_{17}ClCuN_8O_4$ (496.38): calcd. C 41.14, H 3.45, N 22.57; found C 41.26, H 3.22, N 22.44.

**$\{[Cu(bdmpp)(\mu\text{-}N_3)](ClO_4)\cdot MeCN\}_n$ (6):** Compound **6** (0.041 g, 80% based on **1**) was isolated as deep green crystals from the reaction of **1** (0.061 g, 0.1 mmol) and $NaN_3$ (0.007 g, 0.1 mmol) followed by a similar workup to that used in the isolation of $\mathbf{2}\cdot 1.5H_2O$. IR (KBr disc): $\tilde{\nu}$ = 3107 (w), 2065 (vs), 2054 (s), 1613 (s), 1565 (m), 1482 (s), 1430 (m), 1391 (m), 1316 (m), 1144 (s), 1118 (s), 1084 (s), 991 (m), 793 (w), 743 (w), 625 (m) $cm^{-1}$. $C_{17}H_{20}ClCuN_9O_4$ (513.41): calcd. C 39.77, H 3.93, N 24.55; found C 39.64, H 3.76, N 24.72.

**$[\{Cu(N_3)(bdmpp)\}_2(\mu\text{-}N_3)_2Cu(N_3)_2]$ (7):** $NaN_3$ (0.026 g, 0.4 mmol) and $CuCl_2\cdot 2H_2O$ (0.017 g, 0.1 mmol) were added to a deep green solution containing **2** (0.044 g, 0.1 mmol) in MeCN (10 mL). The solution was stirred for 20 min; it then darkened and was filtered. Diethyl ether (20 mL) was layered onto the filtrate to form dark brown blocks of **7** (0.033 g, 67% based on **2**) in several days. IR (KBr disc): $\tilde{\nu}$ = 3430.6 (m), 3142 (w), 2066 (vs), 2041 (s), 1614 (s), 1562 (m), 1486 (s), 1418 (m), 1392 (m), 1318 (m), 1139 (m), 1084

the reaction of **3** (0.089 g, 0.1 mmol), $NiCl_2·6H_2O$ (0.048 g, 0.2 mmol), and $NaN_3$ (0.052, 0.8 mmol) followed by a similar workup to that used in the isolation of **7**. IR (KBr disc): $\tilde{\nu}$ = 3433 (m), 3129 (w), 2963 (m), 2085 (s), 2069 (vs), 1613 (s), 1566 (m), 1485 (s), 1420 (m), 1392 (m), 1318 (m), 1261 (s), 1179 (m), 1095 (m), 1024 (s), 988 (m), 801 (s), 740 (w), 670 (w) $cm^{-1}$. $C_{38}H_{46}Cl_2Cu_2N_{32}Ni_2$ (1266.47): calcd. C 36.04, H 3.66, N 35.39; found C 35.82, H 3.52, N 35.33.

**X-ray Structure Determinations:** X-ray-quality crystals of **1**, **2**·1.5$H_2O$, **3**·2MeOH, and **4**–**9** were obtained directly from the above preparations. Measurements of **1**, **3**·2MeOH, **6**, and **7** were made on a Rigaku Mercury CCD X-ray diffractometer by using graphite-monochromated Mo-$K_\alpha$ ($\lambda$ = 0.71070 Å). Single crystals were mounted with grease at the top of a glass fiber and cooled to 193 K in a liquid $N_2$ stream. Cell parameters were refined using the program CrystalClear (Rigaku and MSC, version 1.3, 2001). The collected data were reduced using the program CrystalClear (Rigaku and MSC, version 1.3, 2001) while an absorption correction (multiscan) was applied. Measurements of **2**·1.5$H_2O$, **4**, **5**, **8**, and **9** were made on a Rigaku *R*-axis Spider diffractometer with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å) at 153 K. Data reductions and absorption corrections were performed with the SAINT and SADABS software packages.

All the structures were solved by direct methods and refined on $F^2$ by full-matrix least-squares methods with the SHELXTL-97 program.[40] In the case of **2**·1.5$H_2O$, one water solvent molecule was found to be disordered over two orientations with an occupancy ratio of O(1)/O(1′) = 0.533/0.467. the other water solvent molecule was modeled with an occupancy factor of 0.5. For **4**, one $ClO_4^-$ anion was found to be split over two orientations by rotation around the Cl(2)–O(5) bond, which were refined with occupancy factors of 0.455:0.545 for O(6)/O(6′), O(7)/O(7′), and O(8)/O(8′). All non-hydrogen atoms were refined anisotropically. The H atoms of the water solvent molecules in **2**·1.5$H_2O$ and that of the hydroxy group of the methanol solvent molecule in **3** were located from the Fourier maps. All other H atoms on C atoms were placed in geometrically idealized positions C–H 0.98 Å for methyl groups; C–H 0.95 Å for phenyl groups and pyrazole ring; and constrained to ride on their parent atoms with $U_{iso}$(H) = 1.2$U_{eq}$(C) for phenyl groups and pyrazole ring and $U_{iso}$(H) = 1.5$U_{eq}$(C) for methyl groups. A summary of the key crystallographic information for **1**, **2**·1.5$H_2O$, **3**·2MeOH, and **4**–**9** is given in Tables 6 and 7.

CCDC-651925 (for **1**), -651926 (for **2**·1.5$H_2O$), -651927 (for **3**·2MeOH), -651928 (for **4**), -651929 (for **5**), -651930 (for **6**), -651931 (for **7**), -651932 (for **8**), and -651933 (for **9**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Center via http://www.ccdc.cam.ac.uk/data_request/cif.

# Synthesis, Reactivity, X-ray Crystal Structures and Electrochemical Behaviour of Water-Soluble [Tris(pyrazolyl)borato]ruthenium(II) Complexes of 1,3,5-Triaza-7-phosphaadamantane (PTA)

**Sandra Bolaño,[a] Jorge Bravo,*[a] Jesus Castro,[a] M. Mar Rodríguez-Rocha,[a] M. Fátima C. Guedes da Silva,[b,c] Armando J. L. Pombeiro,*[b] Luca Gonsalvi,[d] and Maurizio Peruzzini*[d]**

**Keywords:** Electrochemistry / Water-soluble complexes / Pyrazolylborates / Ruthenium / N ligands

A series of chloridoruthenium(II) complexes bearing the tripodal ligand tris(pyrazolyl)borate (Tp), the water-soluble cage phosphane 1,3,5-triaza-7-phosphaadamantane (PTA) and its *N*-boranyl adduct PTA($BH_3$), together with $PPh_3$, have been synthesised. The corresponding monohydrido complexes have also been obtained by treating the chlorides with NaOMe. The X-ray crystal structures of [TpRuCl(PTA)($PPh_3$)] (**2**) and [TpRuCl(PTA)$_2$] (**3**) are also described. Cyclic voltammetry (CV) studies in MeCN and dmso generally show reversible $Ru^{II/III}$ oxidation waves and the values of $E_{1/2}^{ox}$ reflect the electron-donating character of the ligands [Tp (each arm) > PTA > PTA($BH_3$)], whose Lever electrochemical parameter ($E_L$) has been estimated for the first time.

## Introduction

Whereas the chemistry of (cyclopentadienido)- and (pentamethylcyclopentadienido)ruthenium derivatives has been covered in the literature both broadly and in more detail,[1] less attention has been devoted to the corresponding hydrotris(pyrazolyl)borate (Tp) complexes, which have thus received increasing attention in recent years.[2] TpRu complexes containing a variety of co-ligands, particularly N-donors such as diamines, MeCN, pyridine, cycloocta-1,5-diene (cod) and hemilabile phosphanylamine ligands, were first reported about a decade ago,[3,4] the main interest residing in the application of such compounds as active catalysts for the dimerisation of terminal acetylenes or the coupling of phenylacetylene with benzoic acid or allyl alcohols.[4a,5] Tertiary phosphanes have also been used as co-ligands,[6] and complexes such as [TpRuX($PPh_3$)$_2$] (X = Cl or H)[6a,6e,6h] and [TpRu(MeCN)($PPh_3$)$_2$]$BF_4$[6e] have been shown to be quite efficient catalyst precursors for such reactions.[5,6e,7] Recent intriguing applications of TpRu complexes have been reported by Gunnoe and co-workers and include the use of [TpRuX($PMe_3$)$_2$] (X = non-dative heteroatomic ligands such as OH, OMe, OPh or NHPh) for the catalytic H/D exchange between water and deuterated arenes,[8] and the spectacular catalytic hydroarylation of α-alkenes promoted by [TpRuPh(CO)(MeCN)] to give alkylarenes with good preference for the linear isomers over the branched ones.[9] Extension of this hydroarylation protocol to multiple C–X (X = O, S) bonds has also been demonstrated.[10] The hydration of nitriles to amides catalysed by the hydride [TpRuH($PPh_3$)(MeCN)] has also been reported and is considered to be assisted by formation of an Ru–H···H–OH dihydrogen-bonding interaction in the transition state, which lowers the reaction barrier for the hydration step.[11]

The coordination properties of the Tp anion and substituted derivatives have been described in detail by Trofimenko, who has discussed their analogies and differences with cyclopentadienido ligands.[2,12] A good example of this is the comparison between [TpRuCl($PPh_3$)$_2$] and [CpRuCl($PPh_3$)$_2$],[13] where the higher reactivity of the former towards ligand substitution has been ascribed to both the higher nucleophilicity imparted to the metal atom by Tp, which labilises the Ru–Cl bond, and the higher steric constraint caused by the bulkier tris(pyrazolyl) framework. Another aspect of this class of tripodal ligands, which is recognized as being beneficial in their catalytic application, is their hemilability and the consequent easy change of hapticity from $\kappa^3$- to $\kappa^2$-coordination.[14]

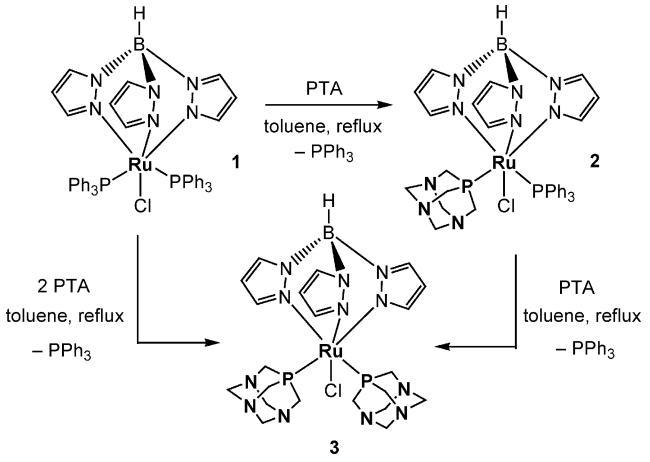
We have been interested for some years in the organometallic reactivity and application in catalysis of water-soluble phosphanes such as 1,3,5-triaza-7-phosphaadamantane (PTA),[15] and we recently communicated the synthesis of its *N*-$BH_3$ adduct [PTA($BH_3$)].[16] To the best of our knowledge, no examples of TpRu complexes bearing monodentate water-soluble phosphanes are known in the literature.[17] Herein we describe the synthesis of a series of novel $TpRu^{II}$ chlorido and hydrido complexes bearing various combinations of PTA, PTA($BH_3$) and $PPh_3$ as ancillary ligands, together with the X-ray crystal structure determinations of selected complexes. The cyclic voltammetric behaviour of the TpRu complexes is also reported as it provides interesting information on the donor abilities of the ligands.



Scheme 1.

## Results and Discussion

### Synthesis and Characterisation of TpRu Complexes with PTA and PTA($BH_3$)

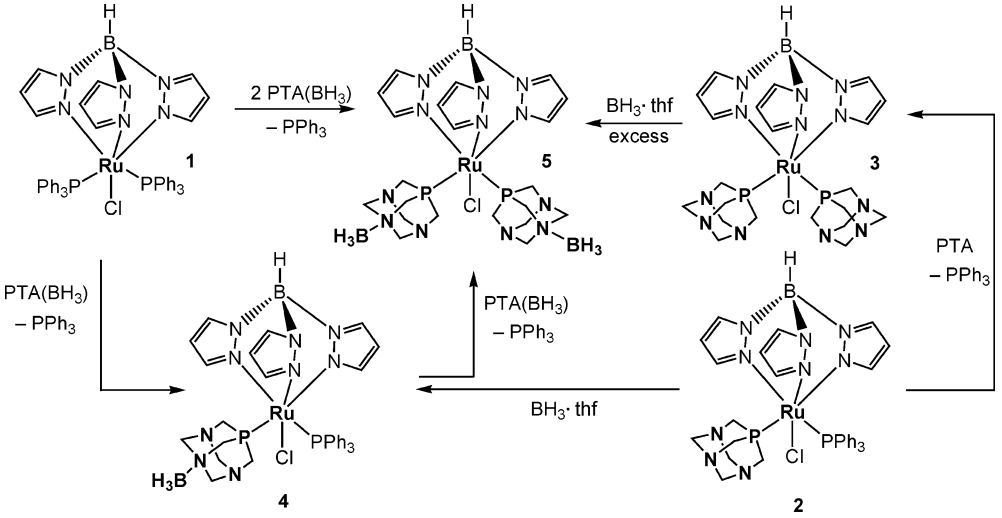
The novel [tris(pyrazolyl)borato]ruthenium(II) complexes [TpRuCl(PTA)($PPh_3$)] (**2**) and [TpRuCl($PTA)_2$] (**3**) were prepared in good yields by treating [TpRuCl($PPh_3)_2$] with PTA in refluxing toluene in the molar ratio 1:1 or 1:2, respectively. Alternatively, compound **3** can be synthesised by treating **2** with PTA in refluxing toluene (Scheme 1).

A similar reaction with the *N*-boranyl adduct of PTA [PTA($BH_3$)] gives the complexes [TpRuCl($PPh_3$){PTA-($BH_3$)}] (**4**) and [TpRuCl{PTA($BH_3)_2$}] (**5**). Alternatively, the TpRu complexes **4** and **5**, which contain the boronated PTA ligand, may be prepared in a straightforward manner by direct boronation of **2** and **3** in thf with excess $BH_3$·thf at room temperature. Whereas the reaction proceeds smoothly for **2** in a 1:1 ratio to give compound **4** in good yield, an excess of $BH_3$·thf has to be added to **3** in order to obtain **5** (Scheme 2) as the only product of the reaction (see below).

Whilst monitoring the reaction of **3** with increasing amounts of $BH_3$·thf by $^{31}P\{^1H\}$ NMR spectroscopy, we observed, in addition to the signals corresponding to complex **5**, the appearance of two new doublets ($\delta$ = –18.4 and –29.6 ppm, $^2J_{P,P}$ = 35.7 Hz), which progressively disappear as the singlet due to **5** increases in intensity. Although we did not attempt to isolate the complex first formed from **3**, the two doublets may be reasonably attributed to the formation of the intermediate mixed species [TpRuCl-(PTA){PTA($BH_3$)}] (**5′**).

Monitoring of the reaction between **2** (or **3**) and excess $BH_3$·thf by $^{31}P\{^1H\}$ NMR spectroscopy in situ does not provide evidence for the formation of boronated species other than **5**. The absence of NMR signals ascribable to ruthenium complexes containing polyboronated ligands [PTA($BH_3)_x$, $x$ = 2, 3][16a] raises the question as to whether the *N*,*N*-diboronated PTA skeleton may still represent a valid P-type ligand for metal coordination.

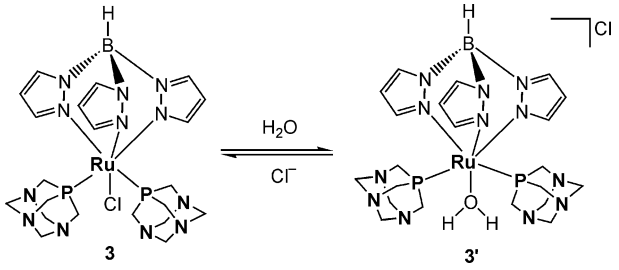
Good analytical data were obtained for all complexes **2**–**5**, which were isolated as fairly air-stable yellow solids. Their solubility in common solvents depends strongly on



Scheme 2.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

the nature of the phosphanes contained in the complexes. Thus, **2** is soluble in most common polar organic solvents but only slightly soluble in water ($S_{25°C}$ = 2.1 mg mL$^{-1}$), whereas replacement of the second $PPh_3$ ligand by PTA makes **3** water-soluble ($S_{25°C}$ = 18 mg mL$^{-1}$). Solutions of **3** in $D_2O$ are stable at room temperature for several days, as indicated by the corresponding $^{31}P\{^1H\}$ NMR spectrum, which displays a singlet at $\delta$ = –26.1 ppm that remains unchanged. A new, slightly deshielded singlet slowly appears at $\delta$ = –24.0 ppm upon heating to 60 °C, and these two signals reach comparable intensities at this temperature after 6 d. This new signal may be safely attributed to aquation of the chlorido derivative to give the cationic aquo complex $[TpRu(H_2O)(PTA)_2]Cl$ (**3′**) (Scheme 3). Ligand substitution in related Ru(PTA) complexes, such as the antitumour compounds $[(\eta^6\text{-arene})RuCl_2(PTA)]$[18] and the corresponding Cp analogue, $[CpRuCl(PTA)(PPh_3)]$,[19] has also been reported. Quantitative formation of the same aquo cation takes place at 60 °C upon mixing $D_2O$ solutions of $TlPF_6$ and **3** (NMR-tube experiment). No attempt was made to isolate the aquo complex in the solid state.



Scheme 3.

Boronation of PTA decreases the solubility of the complexes, making **4** sparingly soluble in halogenated solvents and acetone and insoluble in water. Complex **5**, which bears two boronated $PTA(BH_3)$ ligands, is practically insoluble in common organic solvents except dmso.

All complexes were fully characterised by elemental analysis and conventional spectroscopic techniques (IR and NMR) and, in the case of compounds **2** and **3**, crystals suitable for an X-ray analysis were obtained (see below). The IR spectra of compounds **2**–**5** show the characteristic $\nu_{BH}$ band of the Tp ligand at 2475–2508 cm$^{-1}$. Complexes **4** and **5** also exhibit three absorptions between 2267 and 2376 cm$^{-1}$ due to the stretching modes of the *N*-coordinated borane ($BH_3$) unit. The $^1H$ NMR spectra of compounds **2**–**5** confirm the presence of the Tp ligand, showing the characteristic signals of the pyrazolyl protons in the range $\delta$ = 5.68–8.17 ppm. As expected, the complexity of the Tp signal depends on the degree of symmetry of the molecule due to homo- or heterophosphane substitution, and the same trend was observed in the $^{13}C$ NMR spectra, which were fully assigned (see Experimental Section) with the help of $^1H$,$^{13}C$-HSQC and DEPT-135 NMR experiments.

The $^{31}P\{^1H\}$ NMR spectrum of **2** shows two doublets at $\delta$ = –34.2 and 46.9 ppm ($^2J_{P,P}$ = 33.1 Hz) corresponding to the phosphorus resonances of PTA and $PPh_3$, respectively. Compound **3** presents a singlet at $\delta$ = –28 ppm corresponding to the P nuclei of both PTA ligands. Compounds **4** and **5** give a similar pattern, with two doublets at $\delta$ = –25.3 and 44.0 ppm ($^2J_{P,P}$ = 32.6 Hz) for compound **4** and a singlet at $\delta$ = –19.5 ppm for compound **5**, which is shifted downfield due to the influence of the $BH_3$ group. The presence of an $N_{PTA}$-coordinated borane unit is further confirmed by broad signals in the $^1H$ NMR spectra between $\delta$ = 0.74 and 1.54 ppm that integrate for three (**4**) or six protons (**5**), respectively.

## Single-Crystal X-ray Structure Determination for Complexes 2 and 3

Suitable crystals of **2** and **3** were grown from dilute toluene solutions. Selected bond lengths and angles are summarised in Table 1, while thermal ellipsoid representations of the solid-state structures of one of the molecules in the asymmetric unit of $[TpRuCl(PTA)(PPh_3)]$ (**2**) and $[TpRuCl(PTA)_2]$ (**3**), along with the atomic numbering schemes, are depicted in Figures 1 and 2, respectively.

[a] Symmetry transformations used to generate equivalent atoms: i: *x*, 3/2 – *y*, *z*.

In keeping with the solution characterisation, both compounds consist of discrete molecules where the ruthenium(II) ion exhibits a distorted octahedral geometry with three contiguous coordination positions occupied by the $\kappa^3$-*N*,*N*′,*N*′′ tridentate Tp ligand. One chlorido ligand and two mutually *cis*- oriented phosphane ligands (two *P*-bonded PTA ligands for **3** and one *P*-bonded PTA and one triphenylphosphane ligand for **2**) complete the coordination polyhedron around the ruthenium atom. The nitrogen-donor atoms of the Tp ligand occupy one of the faces of the octahedron, with the shorter Ru–N bond corresponding

to that *trans* to the chlorido ligand. The Ru–N bonds *trans* to phosphorus atoms in **3** are identical on symmetry grounds and differ by 0.01 and 0.03 Å in the two molecules of **2**. These values are analogous to those found for other Tp–$Ru^{II}$ complexes.[20]

The average Ru–Cl bond length (2.42 Å) is similar to previously published values.[4d,6a,6b,7,21] The Ru–$P_{PTA}$ bond lengths in **3** and **2** are 2.267(1) and 2.288(2) Å, respectively, and are similar to those found for other PTA complexes with ruthenium.[19,21a,22] The angles around the metal atom deviate by less than 4° from the theoretical value of 90° except in two cases. One of these is the P–Ru–P angle, which opens to 98.22(5)° in **3** and 97.87(8)° in **2** despite the fact that the cone angle of $PPh_3$ (approx. 147°) is larger than that of PTA (approx. 102°).[15,22b,23] The other exception involves the N–Ru–N chelate angles of the Tp ligand in the same plane as the phosphorus atoms, which are narrower as a consequence of the variation of the P–Ru–P angles and have values of 81.24(17)° for **3** and 81.1(2)° (av.) for **2**. The *trans* angles diverge from the theoretical value of 180° due to the chelate requirements of the Tp ligand and the steric effects of the phosphane ligands already discussed for the *cis* angles. Thus, the N–Ru–Cl angles have values of between 172.0(1) and 174.6(1)° and the P–Ru–N angles range from 172.0(2) to 173.1(2)°.

## Electrochemical Studies

Electrochemical studies on the present TpRu complexes were carried out to collect information about the donor properties of PTA and its *N*-boranyl adduct. The electrochemical behaviour of $[TpRuCl(PPh_3)_2]$ (**1**) was also investigated in order to compare these properties with triphenylphosphane. In spite of the increasing amount of attention being paid to this class of water-soluble ligands,[15] electrochemical studies on their coordination complexes have rarely been carried out and, to the best of our knowledge, are limited to Darensbourg's analysis of electrocatalysed $H_2$ production by models of iron hydrogenases incorporating PTA and electrophilically activated PTA analogues[24] and to a recent study on (cyclopentadienido)-ruthenium complexes related to the present TpRu species by online electrochemistry and electrospray mass spectrometry (EC/ESI-MS).[25]

The electrochemical behaviour of ruthenium(II) complexes **1**–**5** was studied in MeCN and dmso. Cyclic voltammetry (CV) in 0.2 M $[Bu_4N][BF_4]$ at a Pt disc electrode in both solvents shows a reversible, one-electron oxidation wave assigned to the $Ru^{II} \rightarrow Ru^{III}$ oxidation (wave I, at the half-wave oxidation potential values, ${}^{I}E_{1/2}{}^{ox}$, given in Table 2). Hence, it concerns the $Ru^{II/III}$ redox couple, as has been commonly recognized[26–30] for other $Ru^{II/III}$ complexes and also for the complexes $[CpRuCl(L)(L')]$ (L = PTA, $PPh_3$).[25] The occurrence of a one-electron oxidation was confirmed by exhaustive controlled potential electrolysis (CPE) in MeCN at a potential slightly anodic to that of the peak potential, which led to the consumption of nearly 1 F per mol of complex, with conversion of the oxidation wave to the corresponding reduction one at the same half-wave redox potential.

Table 2. Cyclic voltammetric data for the ruthenium complexes **1**–**5**.[a]

| Complex | MeCN | | dmso | |
|---|---|---|---|---|
| | ${}^{I}E_{1/2}{}^{ox}$ | ${}^{II}E_{p}{}^{ox}$, ${}^{III}E_{p}{}^{ox}$ | ${}^{I}E_{1/2}{}^{ox}$ | ${}^{II}E_{p}{}^{ox}$ |
| $[TpRuCl(PPh_3)_2]$ (**1**) | 0.70[b] | 1.98[c] | 0.74 | 1.11 |
| $[TpRuCl(PPh_3)(PTA)]$ (**2**) | 0.70 | 1.26[d] | 0.70 | 1.13[e] |
| $[TpRuCl(PTA)_2]$ (**3**) | 0.66 | 1.23[f] | 0.61 | 1.14 |
| $[TpRuCl(PPh_3)\{PTA(BH_3)\}]$ (**4**) | 0.80 | 1.75, 1.87[g] | 0.77 | – |
| $[TpRuCl\{PTA(BH_3)\}_2]$ (**5**) | 0.89[h] | 1.15, 1.23[g] | 0.79 | 1.14 |

[a] Potentials in V (±0.02) vs. SCE, measured at 0.2 $V s^{-1}$. [b] The reversible oxidation wave with a lower current intensity observed at ${}^{I}E_{1/2}{}^{ox}$ = 1.00 V is ascribed to $[(\kappa^2\text{-Tp})RuCl(MeCN)(PPh_3)_2]$. [c] Upon scan reversal, a cathodic reversible wave is detected at 1.26 V. [d] Upon scan reversal, a cathodic reversible wave is detected at 0.89 V. [e] Upon scan reversal, a cathodic reversible wave is detected at 0.85 V. [f] Upon scan reversal, a cathodic reversible wave is detected at 1.03 V. [g] Poorly defined. [h] The reversible oxidation wave with a lower current intensity observed at ${}^{I}E_{1/2}{}^{ox}$ = 0.75 V is assigned to $[TpRuCl(MeCN)\{PTA(BH_3)\}]$.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

A low-intensity reversible oxidation wave was also observed at a slightly higher or lower $E_{1/2}^{ox}$ value with respect to wave I for complexes [TpRuCl($PPh_3$)$_2$] (**1**; Figure 3) and [TpRuCl{PTA($BH_3$)}$_2$] (**5**), respectively, in MeCN. This additional process was assigned to oxidation of the complexes generated in situ by partial ligand displacement by MeCN, which should result in the formation of the acetonitrile adducts [($\kappa^2$-Tp)RuCl(MeCN)($PPh_3$)$_2$] or [TpRuCl(MeCN)-{PTA($BH_3$)}] (see below). This partial ligand displacement appears to occur more extensively in dmso since wave I of the complexes in this solvent usually exhibits a much lower peak current intensity and CPE involves a charge consumption much lower than 1 F per mol of complex. This behaviour can be explained by considering the replacement of one of the coordinating arms of $\kappa^3$-Tp (thus becoming $\kappa^2$-Tp) by dmso (see below) and formation of complexes that exhibit oxidation potentials about 0.4 V above those of the starting complexes (wave I). In fact, a second irreversible oxidation wave (wave II) with a higher current intensity than that of wave I is observed close to the solvent/electrolyte discharge in dmso at an $E_p^{ox}$ value that is 0.35–0.53 V more anodic than that of $^{I}E_{1/2}^{ox}$ (Table 2). This second oxidation wave could also involve a ligand-centred oxidation since free PTA presents an irreversible oxidation wave at 1.05 V vs. SCE.

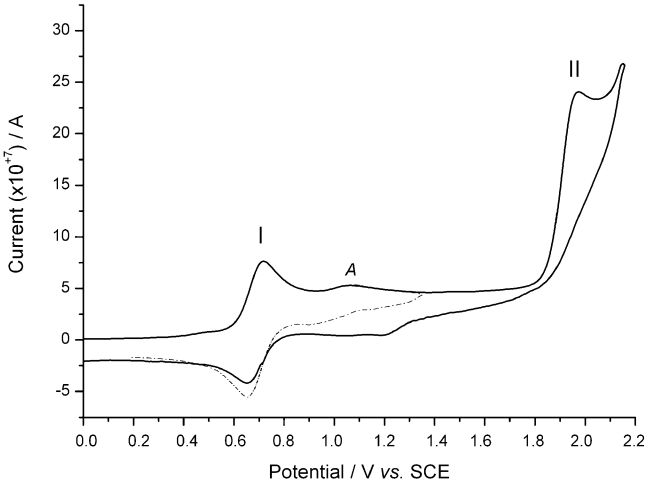

Figure 3. Cyclic voltammograms of [TpRuCl($PPh_3$)$_2$] (**1**) (0.7 mM) in 0.2 M [$Bu_4N$][$BF_4$]/MeCN at a platinum disc ($d$ = 0.5 mm) working electrode and at a scan rate of 0.2 V s$^{-1}$. Wave A is assigned to [($\kappa^2$-Tp)RuCl(MeCN)($PPh_3$)$_2$] (see text). The dotted line represents the cathodic scan following the oxidation waves I and A.

In the cyclic voltammograms in MeCN wave I is also followed at a higher potential by a second (and in a couple of cases also by a third) irreversible oxidation wave (Table 2) which is also believed to be ligand- rather than metal-centred. In fact, the $Ru^{III/IV}$ redox potential would be expected (see below) at a much higher potential (> 2.4 V vs. SCE) and, for example, the potassium salt of Tp in MeCN exhibits irreversible oxidation waves at 1.61 and 1.96 V. Such oxidation waves were not investigated further.

The values of the $Ru^{II/III}$ oxidation potential ($^{I}E_{1/2}^{ox}$) of our complexes should reflect the electron-donor character of the ligands, which thus can be ordered as follows: PTA > $PPh_3$ > PTA($BH_3$). This character can even be measured by applying the redox potential parametrisation approach proposed by Lever[26] for octahedral complexes, based on the linear relationship [Equation (1)] in which the redox potential of a complex (in V vs. NHE) is related to electrochemical parameters determined by the ligands and the metal redox centre. In this equation $\Sigma E_L$ is the sum of the values of the $E_L$ ligand parameter for all the ligands and $S_M$ and $I_M$ are the slope and intercept, respectively (dependent upon the metal, redox couple, spin state and stereochemistry).

$$E_{1/2}^{ox} = S_M \cdot (\Sigma E_L) + I_M \quad (1)$$

Application of Equation (1) to the complexes under study (with the $^{I}E_{1/2}^{ox}$ oxidation potentials converted to V vs. NHE) with known values of $I_M$ (0.04 V vs. NHE) and $S_M$ (0.97) for the $Ru^{II}/Ru^{III}$ redox centre, as well as $E_L$ for the $Cl^-$ and $PPh_3$ ligands (–0.24 and 0.39, respectively)[26] allowed us to tentatively estimate, for the first time, the $E_L$ parameter for Tp (in complex **1**), PTA (in complexes **2** and **3**) and its *N*-boranyl adduct, PTA($BH_3$) (in complexes **4** and **5**) as an average of two (for Tp) or four (for the other ligands) values for each ligand (measured in both MeCN and dmso). The estimated $E_L$ values (Table 3) are as follows: 0.14 V (for each coordinated arm of Tp), 0.34 (PTA) and 0.45 [PTA($BH_3$)] V vs. NHE. This order confirms the ordering above for the net electron-donor ability of such ligands on the basis of the oxidation potentials of their complexes.

Table 3. $E_L$ ligand parameter values estimated in this study.[a]

| Ligand | $E_L$ [V] vs. NHE |
|---|---|
| Tp | 014[b] |
| PTA | 0.34 |
| PTA($BH_3$) | 0.45 |

[a] From Lever's equation [Equation (1)]. [b] Per ligating pyrazolyl arm.

Remarkably, Tp appears to be a net electron-donor similar to $HCpz_3$ [hydrotris(pyrazolyl)methane], for which an identical $E_L$ value has been estimated.[31] However, each pyrazolyl arm of Tp is a slightly weaker electron donor than pyrazole itself ($E_L$ = 0.20 V vs. NHE). Application of Equation (1), using the estimated $E_L$ values, to the above-mentioned unassigned low-intensity oxidation waves at 1.00 and 0.77 V vs. SCE (in MeCN solutions of complexes **1** and **5**), allowed us to tentatively identify the corresponding complexes as [($\kappa^2$-Tp)RuCl(MeCN)($PPh_3$)$_2$] and [TpRuCl(MeCN){PTA($BH_3$)}], which have predicted $E_{1/2}^{ox}$ values of 0.96 and 0.74 V, respectively. The former complex is derived from displacement of one pyrazolyl arm of Tp in **1** by MeCN, whereas the latter complex results from substitution of one PTA($BH_3$) ligand by acetonitrile.

Since *S*-bonded dmso ($E_L$ = 0.57 V)[32] behaves as a considerably weaker net electron-donor than each ligating arm of Tp ($E_L$ = 0.14 V as estimated above) and the corresponding $\Delta E_L$ difference is 0.43 V, coordinative displacement of one pyrazolyl group of Tp (conversion from a tri- to a di-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

hapto ligand) by dmso would result in an increase of the oxidation potential of the complex by a value of $0.43\,S_M$ [Equation (1)], i.e. 0.42 V. This difference is comparable to those observed between the oxidation potentials of the second and first waves (Table 2) in dmso ($\Delta E^{ox}$ in the 0.35–0.53 V range), thereby suggesting the occurrence of such a displacement reaction. This implies that the oxidation waves observed at potentials higher than those of wave I ($Ru^{II/III}$ redox pair) should not be assigned to the $Ru^{III/IV}$ oxidation. Indeed, the estimated $Ru^{III/IV}$ oxidation potentials (approx. 2.4 V vs. SCE), by application of a proposed version of Lever's relationship in which $S_M = 1.03$ and $I_M = 1.68$ V vs. NHE,[28] are much higher than the experimentally measured ones.

### Synthesis and Characterisation of Water-Soluble TpRu Hydrides

The hydrido[tris(pyrazolyl)borato]ruthenium(II) complex [TpRuH($PPh_3$)(PTA)] (**6**) was prepared by chloride metathesis upon treatment of **2** with an excess of NaOMe in MeOH at room temperature. Attempts to prepare this hydride according to the more standard method[33] using $NaBH_4$ as hydride source failed due to partial boronation of PTA. Similarly, the reaction of **2** with $LiHBEt_3$ or $LiAlH_4$ did not afford reproducible results and generally resulted in extensive decomposition. Attempts to prepare the bis(PTA) hydride [TpRuH($PTA)_2$] (**7**) by using NaOMe or similar reagents proved unsuccessful, although treatment of complex **6** with PTA in refluxing toluene was an excellent method to prepare **7**. Further reaction of **6** with $BH_3$·thf provides a straightforward method to synthesise the new PTA-boronated hydrido complex [TpRuH($PPh_3$){PTA-($BH_3$)}] (**8**). A summary of these reactions is shown in Scheme 4.

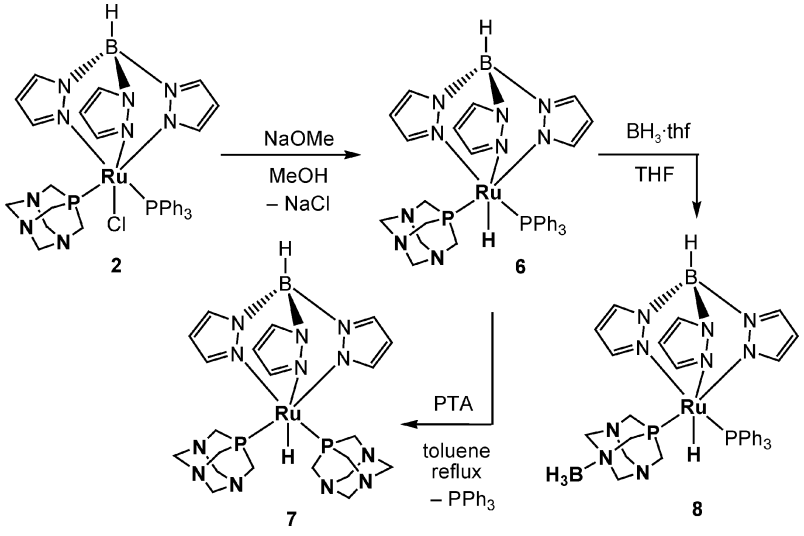
The hydrides **6**–**8**, which were isolated as pale-yellow solids in moderate yields, decompose slowly in air; thus, they were stored under argon. The complexes are soluble in halogenated solvents but slowly revert to the corresponding chloro complexes. The IR spectra of all hydride compounds, apart from the characteristic $\nu_{BH}$ band of the Tp ligand (2456–2464 $cm^{-1}$), show a medium-intensity absorption at 1920–1940 $cm^{-1}$ attributed to $\nu_{RuH}$.

The $^1H$ NMR spectra of compounds **6**–**8** confirm the presence of the Tp ligand by showing the characteristic signals of the pyrazole hydrogen atoms of the Tp group. Again, the number of these signals reflects the number of identical co-ligands attached to the metal centre. The $^1H$ NMR spectra of complexes **6** and **8** show a high-field-shifted doublet of doublets, each centred at $\delta \approx -14$ ppm, due to coupling to two different phosphorus atoms, which is highly diagnostic for the presence of a terminal hydrido ligand, whereas complex **7** displays a triplet at $\delta \approx -16$ ppm corresponding to the single hydrido ligand coupled to the two magnetically equivalent PTA P atoms ($^2J_{P,H} = 30.6$ Hz). A triplet with similar NMR parameters has been reported for the related hydride [CpRuH($PTA)_2$] ($\delta = -14.46$ ppm, $^2J_{P,H} = 36.0$ Hz).[21a,22d]

In agreement with the proposed formulation, the $^{31}P\{^1H\}$ and $^{13}C\{^1H\}$ NMR spectra of hydrides **6**–**8** show similar patterns to the chlorido complexes and do not require additional comment.

Interestingly, while the solubility of the mixed PTA/$PPh_3$ hydride **6** in water is rather modest ($S_{25\,°C} = 2.0$ mg $mL^{-1}$), the bis(PTA) hydride **7** is readily soluble in water ($S_{25\,°C} = 21$ mg $mL^{-1}$), where it does not decompose even upon standing at room temperature for a week.

Water-soluble transition metal hydrides are still uncommon species[34] despite the increased attention recently paid to catalytic applications in water or aqueous biphasic systems and the growing interest in synthesising metal hydrides that combine good water solubility with thermal robustness and tolerance to highly polar substrates. As **6** seems to fulfil these latter requirements, it appears to be a good candidate for further studies and applications in aqueous-phase hydrogenation catalysis. Current work in our laboratories is



Scheme 4.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

aimed at investigating the scope of **6** in catalysis and at preparing new water-soluble transition metal hydrides based on PTA and related systems.

## Conclusions

A series of chloridoruthenium(II) complexes bearing the anionic tripodal tris(pyrazolyl)borato (Tp) ligand and the water-soluble cage phosphane PTA, or its boronated version PTA($BH_3$), have been synthesised and characterised by spectroscopic methods and X-ray diffraction analysis of selected complexes {[TpRuCl(PTA)($PPh_3$)] and [TpRuCl-($PTA)_2$]}. Electrochemical CV studies have indicated the occurrence of partial $\kappa^3$ to $\kappa^2$ dechelation of Tp in some cases, and have allowed us to measure the values of $E_{1/2}^{ox}$, which reflect the electron-donor character of the ligands [Tp (each arm) > PTA > $PPh_3$ > PTA($BH_3$)]; the Lever electrochemical parameter $E_L$ has also been estimated for the first time (except for $PPh_3$).

A series of TpRu hydrides containing PTA and PTA($BH_3$) have been prepared and characterised. The hydride [TpRuH($PTA)_2$], which has been prepared in good yield, shows good solubility in water and high thermal stability. Further studies are in progress to determine the activities of the complexes obtained as hydrogenation catalysts in aqueous and biphasic systems and to evaluate their biological activity towards selected cell lines and their role in medicinal chemistry.[35]

## Experimental Section

**General Methods:** All experimental manipulations were carried out under argon using standard Schlenk techniques. Once isolated, the complexes were found to be relatively stable in air, but were stored for precaution under an inert gas. All solvents were purified by conventional procedures[36] and distilled prior to use. The ligands PTA,[37] PTA($BH_3$),[16a] KTp[12a] and the complex [TpRuCl-($PPh_3)_2$][6a] (**1**) were prepared according to published methods. Other reagents were purchased from commercial sources in the highest available purity and used as received. IR spectra (KBr disc) were recorded with a Bruker Vector IFS 28 FT spectrophotometer. NMR spectra [$^1$H, $^{31}$P($^1$H), $^{13}$C($^1$H)] were obtained at room temperature (25 °C) with a Bruker ARX-400 spectrometer operating at frequencies of 400, 161 and 100 MHz, respectively; the spectra were recorded in $CDCl_3$, [$D_6$]dmso, $D_2O$ or $CD_2Cl_2$ solution using the solvent as internal reference. $^1$H and $^{13}$C{$^1$H} NMR signals are referenced to internal TMS and those of $^{31}$P{$^1$H} to 85% $H_3PO_4$; downfield shifts ($\delta$ in ppm) are considered positive. The $^1$H,$^1$H-COSY, $^1$H,$^{13}$C-HSQC 2D-NMR experiments were performed with the same instrument using standard programs and processing routines. Microanalyses were carried out with a Fisons EA-1108 elemental analyzer.

**Synthesis of [TpRuCl(PTA)($PPh_3$)] (2):** Solid PTA (180 mg, 1.14 mmol) was added to a stirred suspension of [TpRuCl($PPh_3)_2$] (**1**; 1000 mg, 1.14 mmol) in 20 mL of toluene, and the reaction mixture was refluxed for 40 min. The resultant yellow solution was filtered through Celite while hot to remove impurities. The yellow filtrate was reduced under vacuum to about 3 mL, and a yellow microcrystalline solid was precipitated upon addition of diethyl ether (5 mL). This precipitate was collected on a sintered glass frit and washed with diethyl ether (3 × 10 mL) before being dried in vacuo. Yield: 740 mg (84%). $S_{25\,°C}$ = 2.1 mg mL$^{-1}$. $C_{33}H_{37}BClN_9P_2Ru$ (769.0): calcd. C 51.54, H 4.85, N 16.39; found C 51.50, H 4.87, N 16.35. IR (KBr pellet): $\nu_{BH}$ = 2475 cm$^{-1}$ (w). $^1$H NMR ($CDCl_3$, 400 MHz): $\delta$ = 3.88 (m, 6 H, PC$H_2$N), 4.20–4.46 (m, NC$H_2$N, 6 H), 5.68 [t, $^3J_{H,H}$ = 2.3 Hz, 1 H, HB-($C_3H_3N_2)_3$], 5.77 [td, $^3J_{H,H}$ = 2.2, $^5J_{H,P}$ = 1.0 Hz, 1 H, HB-($C_3H_3N_2)_3$], 5.98 [d, $^3J_{H,H}$ = 2.1 Hz, 1 H, HB($C_3H_3N_2)_3$], 6.21 [td, $^3J_{H,H}$ = 2.2, $^5J_{H,P}$ = 1.0 Hz, 1 H, HB($C_3H_3N_2)_3$], 6.62 [d, $^3J_{H,H}$ = 2.1 Hz, 1 H, HB($C_3H_3N_2)_3$], 7.22–7.30 (m, 3 H, P$Ph_3$), 7.30–7.37 (m, 6 H, P$Ph_3$), 7.52–7.63 [m, 6 H, P$Ph_3$, 3 H, HB($C_3H_3N_2)_3$], 8.17 [d, $^3J_{H,H}$ = 2.1 Hz, 1 H, HB($C_3H_3N_2)_3$] ppm. $^{13}$C{$^1$H} NMR ($CDCl_3$, 100 MHz): $\delta$ = 51.9 (d, $^1J_{C,P}$ = 13.4 Hz, P$CH_2$N), 73.4 (d, $^3J_{C,P}$ = 5.6 Hz, N$CH_2$N), 105.2 [d, $^4J_{C,P}$ = 2.1 Hz, HB($C_3H_3N_2)_3$], 105.7 [d, $^4J_{C,P}$ = 2.1 Hz, HB($C_3H_3N_2)_3$], 105.8 [s, HB($C_3H_3N_2)_3$], 127.5–130.0 (*C* $PPh_3$), 133.4–136.6 (*C* $PPh_3$), 135.3 [s, HB-($C_3H_3N_2)_3$], 135.5 [s, HB($C_3H_3N_2)_3$], 135.9 [s, HB($C_3H_3N_2)_3$], 143.5 [s, HB($C_3H_3N_2)_3$], 144.2 [s, HB($C_3H_3N_2)_3$], 146.6 [s, HB-($C_3H_3N_2)_3$] ppm. $^{31}$P{$^1$H} NMR ($CDCl_3$, 161 MHz): $\delta$ = –34.2 (d, $^2J_{P,P}$ = 33.1 Hz, $P_{PTA}$), 46.9 (d, $^2J_{P,P}$ = 33.1 Hz, $P_{PPh_3}$) ppm.

**Synthesis of [TpRuCl($PTA)_2$] (3). Method A:** Solid PTA (90 mg, 0.57 mmol) was added to a stirred suspension of **1** (200 mg, 0.23 mmol) in 10 mL of toluene, and the reaction mixture was refluxed for 4 h. The resulting yellow precipitate was filtered and washed with diethyl ether (3 × 5 mL) and ethanol (3 × 5 mL) before being dried in vacuo. Yield: 128 mg (84%). **Method B:** Solid PTA was added (20 mg, 0.13 mmol) to a yellow solution of **2** (100 mg, 0.13 mmol) in hot toluene (10 mL), and the reaction mixture was stirred and refluxed for 3 h. The resulting yellow precipitate was filtered and washed with diethyl ether (3 × 5 mL) and ethanol (3 × 5 mL) before being dried in vacuo. Yield: 71 mg (83%). $S_{25\,°C}$ = 18 mg mL$^{-1}$. $C_{21}H_{34}BClN_{12}P_2Ru$ (663.87): calcd. C 37.99, H 5.16, N 25.32; found C 37.96, H 5.19, N 25.21. IR [KBr pellets]: $\nu_{BH}$ 2508 cm$^{-1}$ (w). $^1$H NMR ($CDCl_3$, 400 MHz): $\delta$ = 4.13 (s, 12 H, PC$H_2$N), 4.44, 4.54 (AB system, $^2J_{AB}$ = 14.0 Hz, 12 H, NC$H_2$N), 6.19 [br., $^3J_{H,H}$ = 2.4 Hz, 3 H, HB($C_3H_3N_2)_3$], 7.13 [d, $^3J_{H,H}$ = 1.5 Hz, 1 H, HB($C_3H_3N_2)_3$], 7.62 [d, $^3J_{H,H}$ = 2.1 Hz, 2 H, HB($C_3H_3N_2)_3$], 7.72 [d, $^3J_{H,H}$ = 2.3 Hz, 1 H, HB($C_3H_3N_2)_3$], 7.92 [d, $^3J_{H,H}$ = 1.7 Hz, 2 H, HB($C_3H_3N_2)_3$] ppm. $^{13}$C{$^1$H} NMR ($CDCl_3$, 100 MHz): $\delta$ = 53.9 (d, $^1J_{C,P}$ = 7.1 Hz, P$CH_2$N), 73.4 (d, $^3J_{C,P}$ = 3.2 Hz, N$CH_2$N), 105.8, 106.3, 135.4, 136.7, 143.2, 146.9 [all s, HB($C_3H_3N_2)_3$] ppm. $^{31}$P{$^1$H} NMR ($CDCl_3$, 161 MHz): $\delta$ = –28.3 ppm (s); ($D_2O$, 161 MHz): $\delta$ = –26.1 ppm (s).

**Synthesis of [TpRuCl($PPh_3$){PTA($BH_3$)}] (4). Method A:** Solid PTA($BH_3$) (97 mg, 0.57 mmol) was added to a stirred suspension of **1** (500 mg, 0.57 mmol) in 15 mL of toluene, and the reaction mixture was gently refluxed for 40 min. The yellow solution was filtered through Celite while hot, and the yellow filtrate was concentrated under vacuum to about 4 mL. Addition of diethyl ether (5 mL) gave **4** as a yellow microcrystalline solid, which was filtered and washed with diethyl ether (3 × 10 mL) before being dried in vacuo. Yield: 295 mg (66%). **Method B:** $BH_3$·thf was added with a syringe (0.4 mL, 0.4 mmol) to a suspension of **2** (300 mg, 0.39 mmol) in 20 mL of thf. The yellowish mixture was stirred at room temperature for 1 h before being filtered through Celite. The filtrate was concentrated under vacuum to about 4 mL, and diethyl ether (5 mL) was added to give a yellow solid, which was washed with diethyl ether (3 × 5 mL) and ethanol (3 × 5 mL) before being dried in vacuo. Yield: 262 mg (86%). $C_{33}H_{40}B_2ClN_9P_2Ru$ (782.83): calcd. C 50.63, H 5.15, N 16.10; found C 50.59, H 5.21, N 16.03. IR (KBr pellet): $\nu_{BH(Tp)}$ = 2478 cm$^{-1}$ (m); $\nu_{BH\{PTA(BH_3)\}}$ = 2364 (s), 2314 (m), 2267 (m). $^1$H NMR ($CDCl_3$, 400 MHz): $\delta$ = 0.90–1.44

**Synthesis of [TpRuCl{PTA(BH$_3$)}$_2$] (5). Method A:** Solid PTA(BH$_3$) (49 mg, 0.29 mmol) was added to a stirred suspension of **1** (100 mg, 0.11 mmol) in 10 mL of toluene, and the mixture was heated to reflux for 4 h. Workup as described above gave a yellow precipitate, which was collected by filtration through a sintered glass frit and washed with diethyl ether (3 × 5 mL) before being dried in vacuo. Yield: 50 mg (57%). **Method B:** 3 equiv. of BH$_3$·thf (0.4 mL, 0.4 mmol) was added with a syringe to a yellow suspension of **3** (100 mg, 0.15 mmol) in thf (15 mL) whilst stirring. The mixture was stirred at room temperature for 1 h. After removing the volatiles in vacuo, the resulting yellowish solid was washed with diethyl ether (3 × 5 mL) and dried in vacuo. Yield: 81 mg (75%). $C_{21}H_{40}B_3ClN_{12}P_2Ru$ (721.5): calcd. C 36.47, H 5.83, N 24.31; found C 36.25, H 5.85, N 24.39. IR (KBr pellet): $\nu_{BH(Tp)}$ = 2482 cm$^{-1}$ (m); $\nu_{BH\{PTA(BH_3)\}}$ = 2376 (s), 2318 (m), 2275 (m). $^1H$ NMR ([D$_6$]dmso, 400 MHz): $\delta$ = 0.74–1.54 (br., 6 H, B$H_3$), 3.29–4.46 (m, 24 H, C$H_{2\{PTA(BH_3)\}}$), 6.29 [d, $^3J_{H,H}$ = 2.3 Hz, 3 H, HB($C_3H_3N_2$)$_3$], 7.53 [d, $^3J_{H,H}$ = 1.5 Hz, 1 H, HB($C_3H_3N_2$)$_3$], 7.86 [d, $^3J_{H,H}$ = 2.2 Hz, 2 H, HB($C_3H_3N_2$)$_3$], 7.94 [br. s, 3H HB($C_3H_3N_2$)$_3$] ppm. $^{13}C\{^1H\}$ NMR ([D$_6$]dmso, 100 MHz): $\delta$ = 49.5 (d, $^1J_{C,P}$ = 7.4 Hz, P$CH_2$N), 55.2 (d, $^1J_{C,P}$ = 6.4 Hz, P$CH_2$N), 69.4 (br. s, N$CH_2$N), 76.4 (br. s, N$CH_2$N), 105.6 (s, 2 C), 106.9 (s, 1 C), 135.5 (s, 2 C), 137.0 (s, 2 C), 143.3 (s, 1 C), 148.0 [s, 1 C, HB($C_3H_3N_2$)$_3$] ppm. $^{31}P\{^1H\}$ NMR ([D$_6$]dmso, 161 MHz): $\delta$ = –19.5 ppm (s).

**Synthesis of [TpRuH(PPh$_3$)(PTA)] (6):** Solid **2** (200 mg, 0.26 mmol) was added in small portions to a vigorously stirred solution of sodium methoxide prepared by dissolving sodium (30 mg, 1.3 mmol) in 40 mL of methanol, and the reaction mixture was stirred at room temperature for 1.5 h. The mixture was then filtered through Celite to give a yellow solution, which was reduced under vacuum and worked up as above. The yellow solid obtained was washed with ethanol (3 × 5 mL). Yield (90 mg, 47%). $S_{25\,°C}$ = 2.0 mg mL$^{-1}$. $C_{33}H_{38}BN_9P_2Ru$ (734.55): calcd. C 53.96, H 5.21, N 17.16; found C 53.92, H 5.18, N 17.05. **Synthesis of [TpRuH(PTA)$_2$] (7):** Solid PTA (32 mg, 0.20 mmol) was added to a solution of **6** (150 mg, 0.20 mmol) in 10 mL of warm toluene, and the mixture was refluxed for 2 h before being filtered through Celite while hot. Workup of the yellow filtered solution as described above gave the hydride **7** as a yellow precipitate, which was collected by filtration through a sintered glass frit and washed with diethyl ether (3 × 5 mL) and ethanol (3 × 5 mL) before being dried in vacuo. Yield: 40 mg (40%). $S_{25\,°C}$ = 21 mg mL$^{-1}$. $C_{21}H_{35}BN_{12}P_2Ru$ (629.42): calcd. C 40.07, H 5.60, N 26.70; found C 39.92, H 5.55, N 26.63. IR (KBr pellet): $\nu_{BH}$ = 2464 cm$^{-1}$ (w); $\nu_{RuH}$ = 1866 (w). $^1H$ NMR ($CD_2Cl_2$, 400 MHz): $\delta$ = –15.96 (t, $^2J_{P,H}$ = 30.6 Hz, 1 H, Ru*H*), 3.75, 3.89 (AB system, $^2J_{AB}$ = 15.0 Hz, 12 H, PC$H_2$N), 4.31, 4.40 (AB system, $^2J_{AB}$ = 13.0 Hz, 12 H, NC$H_2$N), 6.08 [br. s, 2 H, HB($C_3H_3N_2$)$_3$], 6.26 [br. s, 1 H, HB($C_3H_3N_2$)$_3$], 7.53 [br. s, 1 H, HB($C_3H_3N_2$)$_3$], 7.57 [br. s, 2 H, HB($C_3H_3N_2$)$_3$], 7.63 [br. s, 2 H, HB($C_3H_3N_2$)$_3$], 7.75 [br. s, 1 H, HB($C_3H_3N_2$)$_3$] ppm. $^{31}P\{^1H\}$ NMR ($CD_2Cl_2$, 161 MHz): $\delta$ = –16.8 (s) ppm.

**Synthesis of [TpRuH(PPh$_3$){[PTA(BH$_3$)}] (8):** A slight excess of BH$_3$·thf (0.2 mL, 0.2 mmol) was added with a syringe to a yellow suspension of **6** (100 mg, 0.14 mmol) in 10 mL of thf and the mixture was stirred at room temperature for 1 h. The resulting solution was filtered through Celite to remove impurities and the filtrate was concentrated to dryness under vacuum. The yellow solid obtained was washed with diethyl ether (3 × 5 mL) and ethanol (3 × 5 mL) before being dried under vacuum. Yield: 58 mg (55%). $C_{33}H_{41}B_2N_9P_2Ru$ (748.39): calcd. C 57.96, H 5.52, N 16.84; found C 57.89, H 5.62, N 16.79. IR (KBr pellet): $\nu_{BH(Tp)}$ = 2464 cm$^{-1}$ (w); $\nu_{BH\{PTA(BH_3)\}}$ = 2368 (m), 2319 (m), 2271 (w); $\nu_{RuH}$ = 1940 (m). $^1H$ NMR ($CD_2Cl_2$, 400 MHz): $\delta$ = –14.58 (dd, $^2J_{H,P}$ = 32.5, $^2J_{H,P}$ = 24.6 Hz, 1 H, Ru*H*), 0.60–1.59 (br., 3 H, B$H_3$), 3.03–4.17 (m, 12 H, C$H_2$), 5.58 [br. s, 1 H, HB($C_3H_3N_2$)$_3$], 6.11 [br. s, 1 H, HB($C_3H_3N_2$)$_3$], 6.19 [br. s, 1 H, HB($C_3H_3N_2$)$_3$], 6.40 [br. s, 1 H, HB($C_3H_3N_2$)$_3$], 7.15–7.40 [m, 15 H, P$Ph_3$, 1 H, HB($C_3H_3N_2$)$_3$], 7.53 [d, $^3J_{H,H}$ = 2.0 Hz, 1 H, HB($C_3H_3N_2$)$_3$], 7.63 [d, $^3J_{H,H}$ = 2.0 Hz, 1 H, HB($C_3H_3N_2$)$_3$], 7.71 [br. s, 1 H, HB($C_3H_3N_2$)$_3$], 7.87 [d, $^3J_{H,H}$ = 2.0 Hz, 1 H, HB($C_3H_3N_2$)$_3$] ppm. $^{31}P\{^1H\}$ NMR ($CD_2Cl_2$, 161 MHz): $\delta$ = –15.7 (d, $^2J_{P,P}$ = 35.6 Hz, $P_{PTA(BH_3)}$), 68.6 (d, $^2J_{P,P}$ = 35.6 Hz, $P_{PPh_3}$) ppm.

**Electrochemical Studies:** The electrochemical experiments were performed with an EG&G PAR 273A potentiostat/galvanostat connected to a computer through a GPIB interface. Cyclic voltammograms were obtained for 0.2 M solutions of [Bu$_4$N][BF$_4$] in MeCN or dmso at a platinum disc working electrode (0.5 mm diameter) probed by a Luggin capillary connected to a silver wire pseudo-reference electrode; a Pt auxiliary electrode was also employed. Controlled-potential electrolyses (CPE) were carried out in electrolyte solutions with the above-mentioned composition in a two-compartment, three-electrode cell separated by a glass frit and equipped with platinum gauze working and counter electrodes. A Luggin capillary, probing the working electrode, was connected to a silver wire pseudo-reference electrode. The CPE experiments were monitored regularly by cyclic voltammetry (CV), thus assuring that no significant potential drift occurred during the electrolyses. The electrochemical experiments were performed under $N_2$ at room temperature. The potentials of the complexes were measured by CV in the presence of the couple [Fe($\eta^5$-$C_5H_5$)$_2$]$^{0/+}$ as the internal standard ($E_{1/2}^{ox}$ = 0.45 V vs. SCE both in MeCN and dmso)[38] and the

redox potential values are normally quoted relative to the SCE. However, for the application of the Lever equation [Equation (1)] they were converted to V vs. NHE by adding 0.245 V.

**Crystallographic Studies:** Data were collected with a Siemens Smart CCD area-detector diffractometer with graphite-monochromated Mo-$K_\alpha$ radiation. Absorption correction was carried out using SADABS.[39] The crystallographic calculations were performed with the Oscail program.[40] The structures were solved by Patterson methods and refined by a full-matrix least-squares procedure based on $F^2$.[41] Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were included in idealised positions and refined with isotropic displacement parameters. In both cases the Squeeze program[42] was used to correct the reflection data for diffuse scattering due to disordered solvent. Atomic scattering factors and anomalous dispersion corrections for all atoms were taken from the International Tables for X-ray Crystallography.[43] Further details of crystal data and structural refinement are given in Table 4. CCDC-651193 (**2**) and -651192 (**3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

## Acknowledgments

The authors would like to thank the EC for promoting this scientific activity through the FP6 Research Training Network AQUACHEM (contract MCRTN-2003-503864). Thanks are also expressed to "Firenze Hydrolab", a project sponsored by a Ente Cassa di Risparmio di Firenze, and to the Fundação para a Ciência e a Tecnologia (Portugal) and its POCI 2010 programme (FEDER funded), for financial support. S. B. thanks the Xunta de Galicia for a Parga Pondal contract. M. R.-R. thanks the Xunta de Galicia for a postgraduate grant.

# First $Ni^{II}$–$Ln^{III}$ Coordination Polymers Constructed by Using $[Ni(bpca)_2]$ as a Building Block [Hbpca = bis(2-pyridylcarbonyl)amine]: Synthesis, Crystal Structures and Magnetic Properties

**Augustin M. Madalan,[a] Kevin Bernot,[b,c] Fabrice Pointillart,[b] Marius Andruh,*[a] and Andrea Caneschi*[b]**

**Keywords:** Nickel / Lanthanides / Heterobimetallic coordination polymers / Magnetic properties

Three new heterobimetallic 1D coordination polymers have been obtained by assembling the $[Ni(bpca)_2]$ complex, as a building block, with lanthanide cations: $[\{Ln(O_2NO)(H_2O)_3\}\{Ni(bpca)_2\}](NO_3)_2{\cdot}3H_2O$ (Ln Gd **1**; Tb **2**; Dy **3**). The three compounds are isostructural and their structure consists of infinite cationic chains with $Ln^{III}$ ions connected by $[Ni(bpca)_2]$ complexes acting as bridging bis-bidentate ligands. The charge of the chains is counterbalanced by uncoordinated nitrate ions. The $Ln^{III}$ ions display a coordination number of nine: four oxygen atoms from the carbonyl groups of the bpca ligands belonging to two $\{Ni(bpca)_2\}$ moieties, two oxygen atoms from a chelating nitrato ion and three water molecules. The magnetic investigation of the gadolinium derivative **1** revealed very weak intrachain $Ni^{II}$–$Gd^{III}$-ferromagnetic interactions ($\theta$ = +0.15 K). The weak intrachain-exchange interactions, as well as the bad magnetic isolation of the chains in the crystals, preclude the single-chain magnet behaviour of compounds **2** and **3**. The out-of-phase, $\chi''$, signal observed with compounds **2** and **3** can be ascribed to the magnetic slow relaxation of the lanthanide ions ($Tb^{III}$, $Dy^{III}$).

## Introduction

The interest in the 3d–4f combined coordination chemistry is strongly related to the tremendous development of molecular magnetism.[1] In the early 1990s $Cu^{II}$ and $Gd^{III}$ ions were extensively employed in making heterometallic complexes, because the exchange interaction between the two ions was found to be ferromagnetic in most cases.[2] Numerous $Cu^{II}$–$Ln^{III}$-polynuclear complexes, ranging from discrete entities to coordination polymers with various dimensionalities and network topologies, were synthesized.[3] In spite of the large spin carried by the $Gd^{III}$ ion ($S$ 7/2), the critical temperatures for the classical molecule-based magnets were found to be very low.[4] The main reason for this is the rather weak exchange interaction between $Cu^{II}$ and $Gd^{III}$. More recently, the interest of chemists moved towards lanthanides exhibiting a high anisotropy, as a prerequisite for designing single-molecule magnets (SMMs) and single-chain magnets (SCMs). The best candidates are terbium(III), dysprosium(III) and holmium(III). Indeed, several SMMs based upon 3d and 4f ($Tb^{III}$, $Dy^{III}$, $Ho^{III}$) ions were reported recently.[5] Moreover, it has been shown that even mononuclear $Tb^{III}$ and $Dy^{III}$ complexes fulfil the conditions to exhibit a slow relaxation of the magnetization.[6] Single-chain magnets constructed from anisotropic lanthanides ions are known as well.[7]

Several synthetic strategies are currently employed to obtain 3d–4f complexes:[1,3] (i) self-assembly processes involving metallo-ligands (building-blocks) and assembling $Ln^{3+}$ cations; (ii) the clever use of dissymmetric bi- or tricompartmental ligands, which are able to interact selectively with the two different metal ions; (iii) the employment of preformed 3d–4f complexes as nodes, by connecting them with various spacers; and (iv) one-pot procedures.

The coordination of the bis(2-pyridylcarbonyl)amine anion, $pbca^-$, to various metal ions generates numerous bischelated complexes, $[M^{II}(bpca)_2]$ and $[M^{III}(bpca)_2]^+$, which can act as ligands towards a second metal ion forming oligonuclear complexes[8] and coordination polymers.[9] Mixed valence $Fe^{II}/Fe^{III}$ chains have also been obtained by assembling low-spin $[Fe(bpca)_2]^+$ or similar cations containing methyl-substituted bpca ligands with $Fe^{2+}$ ions. These compounds exhibit single-chain magnetic behaviour.[10]

Because of their strongly oxophilic character, the lanthanide cations easily interact with the oxygen atoms from the carbonyl groups of the bpca ligands coordinated to the first metal ion to form 3d–4f-heterometallic complexes. In this paper we report on the first one-dimensional coordination polymers constructed from $[Ni(bpca)_2]$ building blocks and $Ln^{3+}$ ions.

## Results and Discussion

### Structures

Three new compounds, with the general formula $[\{Ln(O_2NO)(H_2O)_3\}\{Ni(bpca)_2\}](NO_3)_2{\cdot}3H_2O$, were obtained by self-assembly processes involving neutral $[Ni(bpca)_2]$ building blocks and $Ln^{3+}$ ions (Ln Gd, **1**; Tb, **2**; Dy, **3**). The crystallographic investigation revealed that the three complexes are isostructural (Table 1). Therefore, only the crystal structure of the dysprosium derivative will be described here.

The structure of **3** consists of infinite cationic chains with $Dy^{3+}$ ions connected by $[Ni(bpca)_2]$ complexes acting as bridging bis-bidentate ligands (Figure 1). The charge of the chains is counterbalanced by uncoordinated nitrate ions. The nickel ions are hexacoordinated by the two bpca ligands, as in similar complexes.[9] The Ni–N(amide) distances [2.024(3) and 2.027(3) Å] are slightly shorter than the Ni–N(py) ones [2.110(3), 2.106(3), 2.115(3) and 2.131(3) Å]. So the coordination polyhedron of the nickel ion is slightly compressed.

The dysprosium ion displays a coordination number of nine: four oxygen atoms from the carbonyl groups of the bpca ligands belonging to two $\{Ni(bpca)_2\}$ moieties, two oxygens from a chelating nitrato ion and three water molecules. The Dy–O distances vary between 2.336(3) and 2.481(3) Å. The short distances correspond to the dysprosium–aqua bonds. The distance between the metallic centres within a chain is Dy···Ni 5.865 Å. Other relevant bond lengths are collected in Table 2.

The analysis of the packing diagrams shows that all the chains run along the crystallographic *b* axis. At the supramolecular level, the chains interact through graphite-like π–π contacts (3.38–3.62 Å), which are established between the phenyl rings arising from the bpca ligands from neighbouring chains, resulting in a 3D supramolecular array (Figure 2).

The supramolecular interactions between chains are reinforced by hydrogen-bond networks perpendicular to the direction of the chains. The formation of these hydrogen-bond 2D arrays involves all the coordinated and uncoordinated water molecules and nitrate ions. A detailed view of this network is presented in Figure 3. It is interesting to note that some of the crystallization water molecules self-organize by hydrogen bonds into $(H_2O)_4$ clusters (O2S···O3S···O2S′···O3S′, Figure 3).

The collective effect of the supramolecular interactions plays a certain role in the magnetic properties of these compounds (vide infra).

### Magnetic Properties

In the present study we focused on the following lanthanides as partners for the nickel(II) ion: gadolinium, terbium, dysprosium. The reasons for this are the following: (i) the nature and magnitude of the $Ni^{II}$–$Gd^{III}$-exchange interaction can, in principle, be easily determined since $Gd^{III}$, with an $^8S_{7/2}$ ground term, has no orbital contribution to the magnetic moment and the Heisenberg–Dirac–Van Vleck Hamiltonian can be employed;[11] and (ii) terbium(III) and dysprosium(III) are expected to bring a strong anisotropy to the magnetic moment and, consequently, one important condition to eventually observe the slow relaxation of the magnetization is fulfilled. The nickel(II) ion itself exhibits an anisotropy as a consequence of the zero-field splitting effects.

These compounds are also potentially very appealing from a dynamic point of view. In fact monodimensional compounds based on both 3d and 4f ions are quite recent[12] and to the best of our knowledge none of these display single-chain magnet (SCM) behaviour. As reminded in the introduction, SCMs based either on 3d or 4f ions are already known, but each of these categories of chains has its own drawbacks.

On the one hand, transition ions are obviously good candidates to build SCMs as they generally give rise to strong magnetic-exchange interactions in the system. Hence $Co^{II}$, $Ni^{II}$, $Mn^{III}$, $Fe^{III}$ based SCMs are known.[13] But these ions are slightly anisotropic and this precludes more spectacular slow relaxation. On the other hand, some of the lanthanide cations such as the $Tb^{III}$ and $Dy^{III}$ are highly anisotropic. As the $g_{//}$ values are very large and the $g_{\perp}$ almost vanished, they can be considered as almost perfect Ising ions. However, the magnetic interaction between the 4f ions is rather weak as their magnetic orbitals are highly shielded by the 5s, 5p and 6s ones. In fact, reported 4f-based SCMs also involve organic radicals providing the required strong intrachain-magnetic interaction. Hence these chains are not strictly based on 4f ions but have to be considered as 2p–4f magnetic chains.[7] Finally, a huge amount of work reports quite strong magnetic-exchange interactions between transition and lanthanide ions in molecular complexes.[1–3] Therefore, combining 3d or 4f ions in the same one-dimensional edifice could offer the possibility to enhance the magnetic slow relaxation process in SCMs.

### Static Magnetic Properties

#### *{[{Gd($O_2$NO)($H_2O$)$_3$}{Ni(bpca)$_2$}]($NO_3$)$_2$·3$H_2O$}$_n$ (1)*

The thermal variation of the $\chi_M T$ product is shown in Figure 4. It has a constant value equal to 8.99 $cm^3\,K\,mol^{-1}$ from 300 to about 70 K and then it increases slightly. Below 25 K, the $\chi_M T$ product decreases rapidly to reach a value of 7.40 $cm^3\,K\,mol^{-1}$ at 3 K. The value of $\chi_M T$ at room temperature (8.99 $cm^3\,K\,mol^{-1}$) is close to the expected value of 8.96 $cm^3\,K\,mol^{-1}$ for the two isolated $Gd^{III}$ ($S$ 7/2, $g$ 2.00) and $Ni^{II}$ ($S$ 1, $g$ 2.08) complexes. The experimental and calculated magnetizations from 0–6 T are shown in Figure 5. The value of the magnetization at 6 T is 8.6 $\mu_B$, close to the expected saturated value of 9 $\mu_B$ for one $Gd^{III}$ and one $Ni^{II}$ ion; even if the curve is not flat. The calculated magnetization is obtained from a classical Brillouin function for two magnetically isolated $Gd^{III}$ ($S$ 7/2, $g$ 2.00) and $Ni^{II}$ ($S$ 1, $g$ 2.08)[9b] ions.

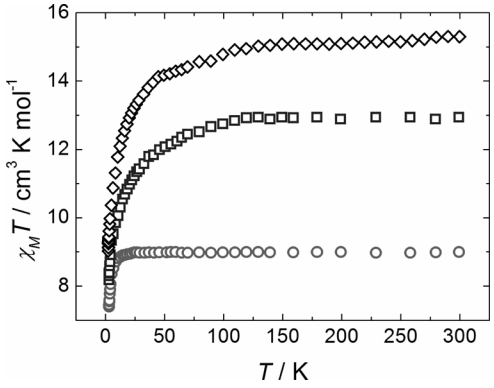

Figure 4. Thermal variation of the $\chi_M T$ product in the temperature range 3–300 K for **1** (gray circles), **2** (dark-gray squares) and **3** (diamonds).

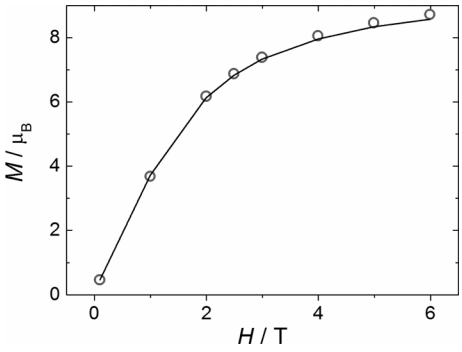

Figure 5. Experimental (gray circles) and calculated Brillouin-function (full black line) magnetizations of **1** over the field range 0–6 T.

The experimental and calculated magnetizations are quasi-superimposed (Figure 5), the magnetic-exchange interaction is indeed supposed to be very weak between the $Ni^{II}$ and $Gd^{III}$ ions through the $bpca^-$ ligand. At high field the calculated magnetization is lower than the experimental one leading to a possible very weak ferromagnetic interaction. The $Gd^{III}$ ion is the only truly isotropic lanthanide ion ($g$ 2.00) and can thus be easily modelled. The ferromagnetic-exchange interaction is confirmed by the weak but positive Curie–Weiss constant $\theta$ +0.15 K, extracted from

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

the fit of the high temperature region of the $\chi^{-1}$ vs. $T$ curve (Figure S1). On the other hand the decrease at low temperatures, out of the fitted region, can be attributed to two phenomena: (i) antiferromagnetic-intermolecular-exchange interactions from the short contacts between two nearest nitrate anions bonded to a $Gd^{III}$ ion leading to the formation of a hydrogen-bond network (Figure 3) and π–π interactions between the phenyl rings of the $bpca^-$ ligands (Figure 2); and (ii) zero-field splitting of the $Ni^{II}$ ions.

### *{[{Tb(O$_2$NO)(H$_2$O)$_3$}{Ni(bpca)$_2$}](NO$_3$)$_2$·3H$_2$O}$_n$ (2) and {[{Dy(O$_2$NO)(H$_2$O)$_3$}{Ni(bpca)$_2$}](NO$_3$)$_2$·3H$_2$O}$_n$ (3)*

The thermal variation of the $\chi_M T$ product and the magnetization curves are shown for the two compounds in Figure 4 and S2, respectively. The values at 300 K are 12.94 $cm^3 K mol^{-1}$ for **2** and 15.30 $cm^3 K mol^{-1}$ for **3**. These experimental values are close to the expected values of 12.90 $cm^3 K mol^{-1}$ and 15.25 $cm^3 K mol^{-1}$, respectively, calculated from the equation $\chi_M T$ $(Ng^2_{Ni}\beta/3k)[S_{Ni}(S_{Ni}+1)]$ + $(Ng^2_{Ln}\beta^2/3k)[J_{Ln}(J_{Ln}+1)]$, with one Ln $Tb^{III}$ ($J$ 6, $g_J$ 3/2) or one Ln $Dy^{III}$ ($J$ 15/2, $g_J$ 4/3)[1a] associated with one $Ni^{II}$ ion ($S$ 1, $g$ 2.08). Both curves show a plateau on cooling until 150 K and then decrease in a monotonous manner. At 3 K the $\chi_M T$ product has a value of 8.30 $cm^3 K mol^{-1}$ and 9.60 $cm^3 K mol^{-1}$ for the $Tb^{III}$ and $Dy^{III}$ derivatives, respectively.

The $Tb^{III}$ ion is a non-Kramer ion having a $^7F_6$ ground state whereas the $Dy^{III}$ ion is a Kramer ion with a $^6H_{15/2}$ ground state.[11] Including them in a one-dimensional compound is of interest as it brings great anisotropy to the system and can give rise to SCM behaviour.[7] However, the fitting of the magnetic data of such a sample is complicated by the strong spin-orbit coupling affecting the lanthanide ions. In particular, the ground state is split into Stark sublevels under the influence of the crystal field.[1b] The crystal-field effects are of the order of 100 $cm^{-1}$ for lanthanides. Consequently when the temperature decreases, the depopulation of these sublevels leads to a deviation from the Curie law leading to a variation of the $\chi_M T$ product even in the absence of any exchange interaction. One can consider that at low temperature only the non-Kramers ground state (for $Tb^{III}$ ion) or Kramers doublet (for $Dy^{III}$ ion) are populated because the energy state separation between the ground state and the first exited state is greater than 1500 $cm^{-1}$.[11] The magnetic properties can thus be modelled using an effective spin $S_{eff}$ 1 (for $Tb^{III}$ ion) and $S_{eff}$ 1/2 (for $Dy^{III}$ ion) with a very anisotropic $g_{eff}$ value. Below 150 K, the decrease of the $\chi_M T$ product for both compounds is therefore attributed to the depopulation of the Stark sublevels of the $Ln^{III}$ ions and not to a magnetic-exchange interaction. This phenomenon hampers the observation of an eventual magnetic-exchange interaction between the $Ni^{II}$ and the $Ln^{III}$ ions. However, some of us, in a previous work on a trinuclear compound of formula {[Ni(bpca)$_2$][Dy(hfac)$_3$](CHCl$_3$)} (noted **4**),[8c] have demonstrated that a weak ferromagnetic-exchange interaction between the $Ni^{II}$ and the $Dy^{III}$ ions through the $bpca^-$ ligand can occur. Moreover previous investigations on similar compounds have shown that with these types of compounds $Dy^{III}$- and $Tb^{III}$-based complexes display magnetic-exchange interactions of the same nature.[1a]

The magnetic analysis of the $Gd^{III}$ derivative gives us evidence of a weak ferromagnetic exchange interaction with the $Ni^{II}$ ion, and hence we found it reasonable to consider that the $Ln^{III}$ and the $Ni^{II}$ ions are weakly ferromagnetically coupled in **2** and **3**. Given the structural configuration of these compounds, we believe that the interchain interactions should be considered as the principal cause of the low temperature decrease of $\chi_M T$. The low value of the intrachain-magnetic interaction, together with the numerous pathways expected to alter the good isolation of the chain, do not allow for a fit of the $\chi_M T$ vs. $T$ curve with a ferromagnetic-chain model.

### Dynamic Magnetic Properties

For the reasons stated above we focus our *ac* analysis on the $Tb^{III}$ (Figure S3) and $Dy^{III}$ (Figure 6) derivatives. In the absence of an external field a small frequency dependence is visible on either the in or out-of-phase signals ($\chi'$ and $\chi''$, respectively). Even if weak, these signals differ notably from the noise of the susceptometer. However, both derivatives display a low $\chi''/\chi'$ ratio, with most of the susceptibility coming from the in-phase component of the magnetization. We thus found it unreasonable to attribute this frequency dependence to a magnetic slow relaxation.

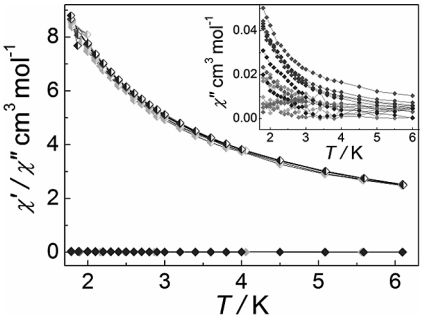

Figure 6. Temperature dependence of the in-phase (half filled symbols) and out-of-phase (filled symbols) susceptibility for **2** (from 100 to 20000 Hz). In the inset the out-of-phase susceptibility is enlarged.

Different reasons may explain the absence of a divergence of the $\chi_M T$ product at low temperature, together with the non-relevant $\chi''$ signal. The first and obvious one is the very weak intrachain-magnetic interaction. As described thanks to the study of **1**, the interaction is very low (Curie–Weiss constant $\theta$ +0.15 K) in these chains. However, no 3D ordering is visible here. This is in contrast with what has been observed in other reported chains.[12] Another reason is the bad magnetic isolation of the chains. The π-stacking interactions (Figure 2) between the chains and the extended network created by the hydrogen bonds (Figure 3) strongly alter the ratio between the intra- and interchain interac-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

tions. This hampers the apparition of a single-chain magnetic behaviour.

In order to further explain the properties of these two chains we want to compare them to the previously cited {[Ni(bpca)$_2$][Dy(hfac)$_3$](CHCl$_3$)} (**4**) compound. This complex is a field dependant SMM, in the sense that its slow relaxation is switched on by a small external field. It thus displays a field dependence at the maximum of the $\chi''$ values. In fact it exhibits a low $\chi''/\chi'$ ratio in the zero-external field, which is a consequence of a fast zero-field tunnelling of the magnetization. Recent results on phthalocyaninate derivatives of lanthanide[6] have shown that this fast tunnelling can be suppressed by applying a small static field. Surprisingly it was found that **2** and **3** do not behave in the same way and do not show any field dependence of the out-of-phase susceptibility.

A last consideration can be made thanks to a close analysis of the molecular structure of **3** and **4**. This latter complex is very similar to the chain. Its inner core formed by the [Ni(bpca)$_2$] moiety is highly similar to that of the chain. The major deviations in the Ni$^{II}$–N$_x$ distances and angles are about 0.02 Å and 2°, respectively. From the magnetic point of view the similarity in the compression of the octahedron around the nickel ion allows us to assume that the anisotropy is equal in **3** and **4**. The main differences between the two compounds are obviously in the environment of the Dy$^{III}$ ions. The {[Ni(bpca)$_2$][Dy(hfac)$_3$](CHCl$_3$)} complex is made up of Dy$^{III}$ coordinated to three hfac$^-$ entities and two oxygen atoms from the bpca$^-$ ligand, which can be considered to be in a *cis* position. This arrangement gives a coordination polyhedron with two quasi-quadrilateral faces composed of four oxygen atoms [torsion angle (O10–O9–O15–O13) 176.6°, (O14–O16–O11–O12) 11.43°]. The coordination polyhedron is close to a square antiprism, a $D_{4d}$ site symmetry.

On the contrary the coordination polyhedron of Dy$^{III}$ in **3** has a different symmetry. Indeed the torsion angle between the four oxygen atoms sharing the possible quadrilateral face is (O2–O1–O6–O5) 165.7°, which is now quite far from the expected 180°. Hence the coordination polyhedron, even if slightly distorted, is close to a 4-capped square antiprism, having a $C_{4v}$ site symmetry.[14]

Ishikawa and coworkers have shown how the magnetic slow relaxation of 4f systems is strongly related to the symmetry of the lanthanide polyhedron.[15] Unfortunately quantitative analyses were only performed for the $D_{3h}$ symmetry. But by the same manner, it seems reasonable to consider that in our case the passage from a $D_{4d}$ to a $D_{2d}$ symmetry affects the dynamic properties of the Dy(hfac)$_3$ moiety. In fact, the crystal field potentials for these two site symmetries are quite different.[16] This may be, together with the above hypotheses, an explanation for the absence of a slow relaxation in **2** and **3**. Over the investigated temperature range we are not able to assign unambiguously the origin of the out-of-phase signal. Given the very low interaction between the magnetic centres along the chain, it seems reasonable to think that the magnetic slow relaxation of the lanthanide ion is one of the origins of the $\chi''$ signal.

## Conclusions

Compounds **1**, **2** and **3** are examples of 3d–4f molecular chains in which the magnetic intrachain interactions are quite weak. This, together with their bad magnetic isolation, hampers the apparition of a magnetic slow relaxation in **2** and **3**. However, we can learn something from these compounds. On comparing them with **4**, the absence of any field dependence of the out-of-phase susceptibility in **2** and **3** may highlight the role played by the symmetry of the lanthanide polyhedron. The use of the lanthanide precursor in an appropriate symmetry environment may be an additional key to favour the slow relaxation of the lanthanide ion in 4f-based compounds. To the best of our knowledge, compounds **1**–**3** are the first coordination polymers constructed by using [M(bpca)$_2$] complexes as building blocks.

## Experimental Section

**Syntheses:** The [Ni(bpca)$_2$] complex was obtained according to ref.[9b] The compounds [{Gd(O$_2$NO)(H$_2$O)$_3$}{Ni(bpca)$_2$}](NO$_3$)$_2$·3H$_2$O (**1**), [{Tb(O$_2$NO)(H$_2$O)$_3$}{Ni(bpca)$_2$}](NO$_3$)$_2$·3H$_2$O (**2**) and [{Dy(O$_2$NO)(H$_2$O)$_3$}{Ni(bpca)$_2$}](NO$_3$)$_2$·3H$_2$O (**3**) were obtained by the same manner: [Ni(bpca)$_2$] (0.05 mmol) was dissolved in a mixture of CHCl$_3$/CH$_3$OH (1:1, 5 mL) and added to a methanolic solution (3 mL) containing Gd(NO$_3$)$_3$·6H$_2$O (0.05 mmol) for **1**, Tb(NO$_3$)$_3$·6H$_2$O (0.05 mmol) for **2** and Dy(NO$_3$)$_3$·5H$_2$O (0.05 mmol) for **3**, respectively. After 2–3 min the combination of the components produced very fine needle-like light-brown crystals. These same solutions, containing the crystalline precipitates, were allowed to stand at room temp. for 1–2 d, which resulted in the dissolution of the precipitates, and further standing for 2 d led to the occurrence of the prismatic light-brown crystals of **1**, **2** and **3**, by slow evaporation.

**Gd(O$_2$NO)(H$_2$O)$_3$}{Ni(bpca)$_2$}](NO$_3$)$_2$·3H$_2$O (1):** Yield 82%. IR data (KBr): $\tilde{\nu}$ = 3375 (s, broad), 1675 (s), 1596 (m), 1563 (m), 1470 (w), 1447 (w), 1382 (vs), 1345 (s), 1283 (m), 1114 (w), 1090 (w), 1043 (w), 1018 (w), 833 (vw), 799 (w), 757 (m), 713 (w), 628 (m), 544 (vw), 517 (w), 418 (w) cm$^{-1}$. **[{Dy(O$_2$NO)(H$_2$O)$_3$}{Ni(bpca)$_2$}](NO$_3$)$_2$·3H$_2$O (3):** Yield 91%. IR data (KBr): $\tilde{\nu}$ = 3356 (s, broad), 1674 (s), 1597 (m), 1561 (m), 1473 (m), 1451 (m), 1384 (vs), 1297 (m), 1150 (vw), 1094 (w), 1046 (w), 1017 (w), 833 (vw), 811 (vw), 759 (m), 720 (w), 634 (m), 519 (w), 420 (w) cm$^{-1}$. C$_{24}$H$_{28}$DyN$_9$NiO$_9$ (967.73): calcd. C 29.76, H 2.89, N 13.02; found C 29.3, H 2.9, N 13.1.

**X-ray Structure Determinations:** X-ray diffraction measurements were performed with a Bruker-Nonius Kappa CCD diffractometer using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). The structures were solved by direct methods and refined by full-matrix least-squares techniques based on $F^2$. The non-H atoms were refined with anisotropic displacement parameters. Calculations were performed using the SHELX-97 crystallographic software package.

CCDC-653381 -653383 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Magnetic Measurements:** All magnetic measurements were performed using pellets in order to avoid orientation of these very anisotropic materials. The *dc*-magnetic susceptibility measurements were performed with a Cryogenic S600 SQUID magnetometer between 2 and 300 K in an applied magnetic field of 0.1 T for temperatures in the range 2–50 K and 1 T for temperatures between 50 and 300 K. These measurements were all corrected for the diamagnetic contribution as calculated with Pascal's constants. The *ac*-magnetic susceptibility measurements were performed on the same samples using a homemade *ac*-probe operating in the range 100–25000 Hz.[17]

**Supporting Information** (see also the footnote on the first page of this article): Temperature dependence of $\chi^{-1}$ for compound **1** (Figure S1), magnetization versus field curves for compounds **2** and **3** (Figure S2), Temperature dependence of the in- and out-of-phase susceptibilities for compound **3** (Figure S3).

## Acknowledgments

We acknowledge the financial support from the Italian Ministero dell'Università e della Ricerca (MURST) (FIRB and PRIN grants), from the The European Commission (EC) through the Human Potential Program RTNQUELMOLNA (MRTN-CT-2003-504880), from the Molecular Approach to Nanomagnets and Multifunctional Materials, Network of Excellence (MAGMANet) (NMP3-CT-2005-515767) and from the Romanian CEEX Program (grant D11-17). F. P. thanks the Deutsche Forschungsgemeinschaft (DFG) (SPP1137) for his post-doctoral fellowship. Prof. R. Sessoli is acknowledged for stimulating discussions.

# A New Donor-Stabilized Ditungsten Amido Alkoxido Species: Synthesis, Crystal Structure, Fluxionality, and Grafting onto Silica

**Olivier Coutelier,[a] Régis M. Gauvin,*[a] Guy Nowogrocki,[a] Julien Trébosc,[a] Laurent Delevoye,[a] and André Mortreux*[a]**

**Keywords:** Tungsten / Metal-metal multiple bonds / Ligand design / Grafting / Silica / Alkyne metathesis

A new dimeric tungsten(III) complex containing amido and chelating pyridine–alkoxido ligands was synthesized through protonolysis of $[W_2(NMe_2)_6]$ by 2-(2-pyridyl)propan-2-ol and fully characterized by X-ray diffraction and infrared and NMR spectroscopy. Intramolecular exchange processes were studied by variable-temperature NMR spectroscopy. The compound was grafted onto dehydroxylated silica by protonolysis of an amido–tungsten bond, and the structure of the supported species was investigated by infrared and solid-state (bidimensional) NMR spectroscopy. The reactivity of the molecular and grafted species toward alkynes was probed.

## Introduction

The recent focus on alkene metathesis following the Nobel prize award to Y. Chauvin, R. R. Schrock, and R. Grubbs has emphasized that the corresponding reaction involving carbon-carbon triple bonds, namely alkyne metathesis,[1] is still a field offering significant challenges.[2] Selectivity of this reaction suffers from side reactions such as trimerization into substituted benzene derivatives, coupling into cyclopentadiene analogues, or polymerization yielding polyacetylenes. The latter reaction is most particularly encountered with terminal alkynes, where the acidity of the terminal C–H induces the rapid formation of polymerization propagating species. Development of new catalysts for this transformation is therefore of considerable interest. Inspired by Schrock's systems based on $[(t\text{BuO})_3W{\equiv}C\text{-}t\text{Bu}]$ and $[(t\text{BuO})_3W{\equiv}W(Ot\text{Bu})_3]$,[3] as well as by our findings on the dramatic influence of quinuclidine as a Lewis base additive in this reaction,[4] we have recently disclosed a new catalytic system that relies on the hemilability concept.[5] Indeed, use of $[W_2(OC(Me)_2CH_2OMe)_6]$ (**2**), in which methoxy donor groups are incorporated within the alkoxido fragments, has led to unprecedented activity for the metathesis of phenylacetylene and 1-heptyne (Scheme 1).[6] The use of alkoxido ligands bearing donor groups thus seems to be a promising approach to develop efficient and selective catalytic systems. In this view, we have chosen to focus on an alkoxido ligand bearing a pyridyl function.[7] Furthermore, Basset and Moore have both reported silica-grafted catalysts displaying high activity and

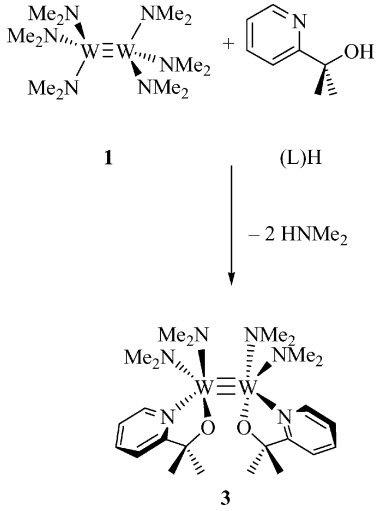
selectivity.[8] On the other hand, we have recently shown that the grafting onto silica of compounds inactive as homogeneous catalysts can afford heterogeneous catalysts active toward terminal alkynes.[9] As the supporting of organometallic species plays a significant role in this chemistry, this prompted us to probe the effect of grafting on other (potential) catalysts.

The present contribution describes our results on the synthesis, solid- and liquid-state structural investigations of a ditungsten complex bearing a bidentate pyridylalkoxido ligand, and on its grafting onto dehydroxylated silica to generate binuclear supported species.

## Results and Discussion

### Synthesis and Characterization of Complex $[W_2(L)_2(NMe_2)_4]$ (3)

The reaction of **1** with 12 equivalents of 2-(2-pyridyl)propan-2-ol, (L)H in toluene at room temperature affords a deep red solution, from which, after stripping off the volatiles and washing with pentane, $[W_2(L)_2(NMe_2)_4]$ (**3**) is obtained as a red-orange solid in 40% yield (Scheme 2). NMR follow-up of the reaction in $C_6D_6$ in the presence of excess (L)H shows that the reaction does not proceed further, despite extended reaction times and more elevated temperatures. In the presence of six equivalents of (L)H, **1** reacts to afford mainly the monosubstituted complex $[W_2(L)(NMe_2)_5]$, on the basis of $^1$H NMR spectroscopic data (see electronic supporting information). The addition of six further equivalents of (L)H to the reaction mixture leads to the selective formation of **3** after 12 h. This differs from the reaction of **1** with *tert*-butyl alcohol, which affords under similar conditions the hexakis(alkoxido) dinuclear complex through complete alcoholysis of the dimethylamido ligands. This is most probably due to the strong binding of the chelating pyridine, which prevents coordination of the bulky alcohol, most probably a prerequisite for the protonolysis of the tungsten–amido bond.



Scheme 2. Synthesis of **3**.

Single crystals suitable for X-ray analysis have been grown in pentane where **3** is slightly soluble. The molecular structure of **3** is depicted in Figure 1. Selected bond lengths and angles are summarized in Table 1.

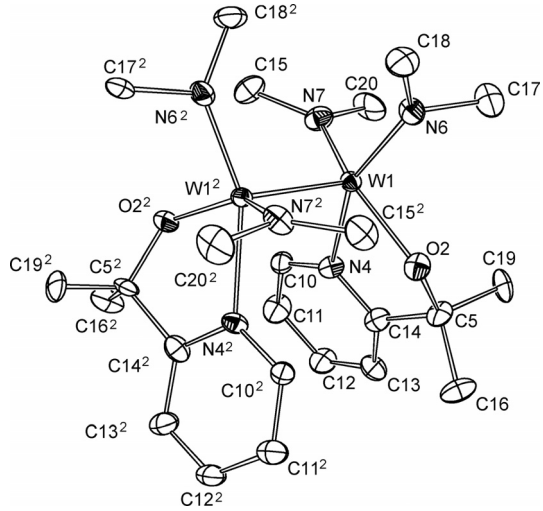


Figure 1. ORTEP representation of **3** with the thermal ellipsoids at 50% of probability. H atoms are omitted for clarity.

Table 1. Selected bond lengths (Å) and angles (°) for complex **3**.

| | | | |
|---|---|---|---|
| W1–W1² | 2.3351(5) | W1–N7 | 1.986(6) |
| W1–N4 | 2.263(5) | W1–N6 | 1.975(6) |
| W1–O2 | 2.021(5) | | |
| N6–W1–N7 | 101.3(2) | O2–W1–N4 | 71.63(18) |
| N6–W1–O2 | 91.7(3) | N6–W1–W1² | 104.05(16) |
| N7–W1–O2 | 144.22(19) | N7–W1–W1² | 101.79(16) |
| N6–W1–N4 | 155.7(2) | O2–W1–W1² | 107.14(13) |
| N7–W1–N4 | 84.13(19) | N4–W1–W1² | 97.81(13) |

Each tungsten of the dimer adopts a distorted square-planar coordination [the sum of angles is 348.8(5)°], composed of two dimethylamido and one chelating pyridylalkoxido ligands. The two tungsten-based fragments are connected by a $C_2$ axis, which intersects the compound at the center of the W–W triple bond. The configuration adopted by the compound is classical for $M_2L_8$ compounds.[10] The two $WL_4$ entities are eclipsed, thus minimizing steric repulsions (Figure 2). The bond lengths are classical: the W1–W1² bond length of 2.3351(5) Å is within the expected range[11] {see for example 2.332(1) in $[W_2(OCHMe_2)_6(py)_2]$[12] or 2.3340(5) in $[W_2(OCH_2tBu)_6(py)_2]$[13]}. The pyridine nitrogen to tungsten bond length [2.263(5) Å] is comparable to that observed in similar complexes.[12,13] The tungsten–amido [1.986(6) and 1.975(6) Å] and tungsten–alkoxido [2.021(5) Å] bond lengths are unexceptional. The two nitrogen amido are planar [sum of angles at N6 and N7 of 359.99(9) and 359.35(8)°, respectively], and the $NMe_2$ fragments are aligned with the W–W triple bond [C18–N6–W1–W1² and C15–N7–W1–W1² dihedral angles of 8.1(7) and 4.5(6)°, respectively]. Thus, proximal methyl groups (C15 and C18) are located over the W–W bond, while distal methyl groups point in the opposite direction.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

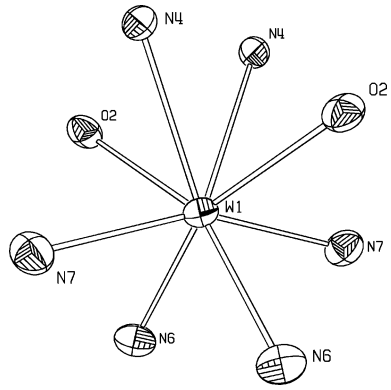

Figure 2. View of the central skeleton of **3** looking down the W1–W1[2] axis.

Room temperature $^1$H NMR spectroscopic data is consistent with the presence of a single type of [N–O] ligand, indicating that the $C_2$ symmetry observed in the solid-state is retained in solution. The pyridyl *ortho* C–H gives rise to a characteristic doublet of triplets in the low field region ($\delta$ = 9.06 ppm). The two diastereotopic methyl groups resonate at $\delta$ = 1.75 and 1.04 ppm. At room temperature, the spectrum comprises three signals for the $NMe_2$ groups at $\delta$ = 4.73, 3.70, and 2.28 ppm, as broad peaks of intensities 6, 12, and 6 H, respectively. This is consistent with two types of $NMe_2$ groups, and is characteristic of hindered rotation around the W–N bond.[14] In order to shed light on the dynamic processes at hand, variable-temperature NMR studies have been carried out (Figure 3). Two different processes involving the two types of $NMe_2$ ligands have been observed (Table 2).

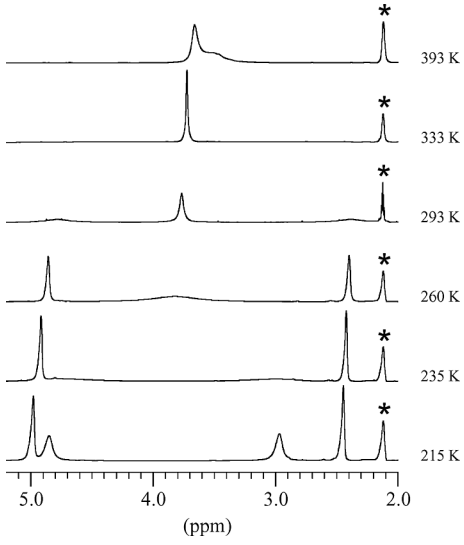

Figure 3. Variable-temperature $^1$H NMR spectra of complex **3** in the *N*-methyl group region ([D$_8$]toluene, 400 MHz; * denotes solvent peak).

On the basis of the literature data,[16] the shielded and deshielded signals within each of these pairs can be respectively assigned to the distal and proximal methyl groups.

Table 2. Variable-temperature NMR studies on **3**: coalescing pairs of signals and corresponding activation energies ([D$_8$]toluene).

| $\delta$ [ppm] | $T_c$ [K] | $\Delta G^{\neq}$ [kJ mol$^{-1}$][15] |
|---|---|---|
| 4.98, 2.44 | 333 (±5) | 60.4 (±0.1) |
| 4.86, 2.96 | 245 (±5) | 44.4 (±0.1) |

This was confirmed by the low-temperature NOESY correlation spectrum, which also allowed us to assign the pairs of signals at $\delta$ = 4.98 and 2.44 ppm and at $\delta$ = 4.86 and 2.96 ppm to the $NMe_2$ group in *cis* and *trans* position to the pyridine, respectively, on the basis of interactions with the pyridine *ortho* CH. This is in agreement with the relative energetic barriers: the $NMe_2$ group *cis* to the pyridine, [$\Delta G^{\neq}$ = 60.4 (±0.1) kJ mol$^{-1}$] is located in a more congested environment (pyridine and $NMe_2$ groups) than the *trans* $NMe_2$ [$\Delta G^{\neq}$ = 44.4 (±0.1) kJ mol$^{-1}$].

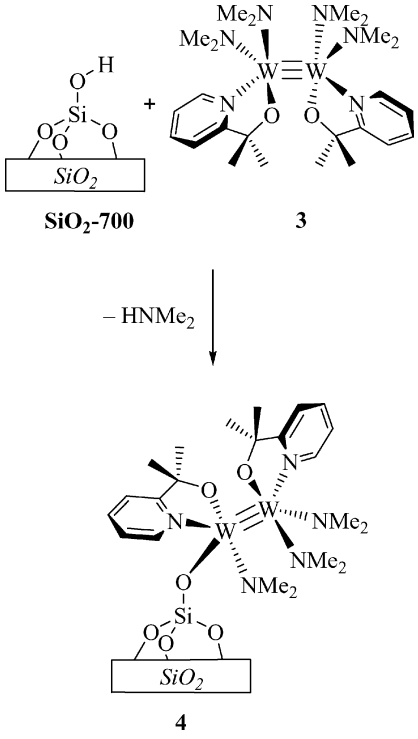
Complex **3** is inactive toward 4-nonyne in the absence of additive. In situ protonolysis with four equivalents of alcohol was attempted to generate $[W_2(OR)_4(L)_2]$ species, bearing in mind the high reactivity of alkoxido species $[W_2(OR)_6]$ in alkyne metathesis. A series of alcohols was screened: *tert*-butyl alcohol, 1-adamantanol, phenol, and 3-quinuclidinol. Only the latter afforded an active catalyst, although a high temperature (363 K) was necessary to reach the thermodynamic equilibrium mixture (1 h). This may be related to this alcohol's coordinative ability through its nitrogen atom. However, further characterization efforts are necessary at this stage to confirm that the amido–tungsten bond protonolysis took place. Moreover, regarding the potential of catalysts bearing this [N,O] ligand in alkyne metathesis, the strongly basic pyridine may hinder the alkyne substrate coordination, a step necessary to cleave the $W_2$ dimer and generate a catalytically active alkylidine species.

## Grafting of Complex 3 Onto Partially Dehydroxylated Silica

These results on the alcoholysis of the W–$NMe_2$ bond producing a metathesis active system prompted us to study the effect of the grafting of **3** onto an inorganic support, since surface hydroxy groups are frequently compared to ROH moieties.[17] Partially dehydroxylated silica was used as a support for the grafting of **3**. Bearing only isolated silanol groups as protic sites on its surface, silica treated under vacuum at 700 °C behaves as a bulky silanol ligand when reacted with organometallic reagents, affording well-defined single site catalysts.[18] Moreover, metal amido species have been grafted with success onto inorganic supports.[8b,19] More precisely, W–$NMe_2$ groups readily react with surface silanols to afford covalent ≡Si–O–W bonds, as shown by the studies on the grafting of **1** onto silica.[8] Grafting of **3** onto $SiO_2$-700 proceeds at room temperature in pentane. During the reaction course, the supernatant color fades from dark to clear orange, while the suspended solid turns to dark red. After three pentane washings and drying at 80 °C for 3 h under a $10^{-6}$ mbar vacuum, **4** is obtained as an ochre powder (Scheme 3). When carrying out

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

the reaction between **3** and suspended partially dehydroxylated silica in $C_6D_6$, the only new compound observed by $^1H$ NMR was $HNMe_2$. No pyridyl alcohol ligand (L)H was detected, which is consistent with the protonolysis of the W–$NMe_2$ bond by ≡SiOH as the preferred grafting mode. Elemental analysis indicates a tungsten content of 10.53 wt.-%. The molar ratios N/W and C/W, respectively of 2.46 and 12.23, are close to values expected for ≡Si–O–[$W_2(L)_2(NMe_2)_3$] (2.50 and 11, respectively), which is in agreement with a clean reaction of complex **3** with isolated surface silanols forming a single W–O–Si bond.



Scheme 3. Grafting of **3** onto partially dehydroxylated silica.

Diffuse reflectance infrared spectroscopic studies on **4** indicate that the silica silanol groups have been entirely consumed, as evidenced from the disappearance of the $\nu_{OH}$ signal at 3747 $cm^{-1}$ [Figure 4, (c)]. This indicates that surface saturation has been reached during the grafting. Moreover, the spectrum of **4** comprises peaks accounting for aromatic C–H bonds (3065 and 3081 $cm^{-1}$) and aliphatic C–H bonds (2974–2769 $cm^{-1}$), as well as aromatic ring-related signals at 1607 and 1568 $cm^{-1}$. For these signals, the similarity with the spectroscopic features of **3** (1600 and 1567 $cm^{-1}$) indicates minor changes within the coordination sphere of the metal.

Solid-state NMR studies on **4** have been carried out to get a better understanding of the grafted species structure. The $^1H$ MAS NMR spectrum comprises peaks analogous to those observed in the $^1H$ solution NMR of **3** (Figure 5). Deconvolution of the spectrum is presented in Figure 6c. Aromatic protons resonate at $\delta$ = 7.2 and 9.3 ppm, the latter being assigned to C–Hs in the *ortho* position of the pyridine

fragment ($C^6H$). Assignment of the signals observed between 4.4 and 0.1 ppm is less straightforward. On the basis of the comparison to the signals of **3**, the peaks at $\delta$ = 4.4 and 2.3 ppm can be unambiguously assigned to NMe groups. Moreover, as a comparison, the $^1$H MAS NMR spectrum of ≡Si–O–[$W_2(NMe_2)_5$] comprises three signals at 4.2, 3.2, and 2.5 ppm.[9] The other three signals at 1.2, 0.8, and 0.1 ppm are assigned to either NMe or diastereotopic CMe groups.[20] The high number of signals is in line with the lowering of the symmetry and increased rotation barriers due to the increased bulk resulting from the silica surface.

The use of a high-field NMR spectrometer (18.8 T, 800 MHz for $^1$H resonance) could not significantly improve the resolution of the $^1$H MAS NMR spectrum due to signal artifacts related to probe background signal overlapping the 0–4 ppm region. However, we have been able to run a Double Quanta MAS experiment[21] on this instrument in order to gain further insight on the structure of the grafted species of **4**. In Figure 6 is presented the spectrum resulting from the double-quantum correlation experiment using one rotor period mixing time for Back-to-Back (BABA) excitation. This technique gives the means to probe proximities between protons for which dipolar coupling is strong. Moreover, it efficiently filters out the artifacts stemming from probe background. The 2QMAS spectrum exhibits the least mobile sites that still experience sufficient dipolar coupling to correlate.

The aromatic protons give rise to two off-diagonal patterns at 9–8 ppm, assigned to the *ortho* pyridine protons based on the characteristic chemical shift, and at 8–7 ppm, for other aromatic protons. These correlations are in line with spatial proximities between these types of CHs. The broad distribution for the *ortho* pyridine protons indicates that these are present in different types of sites. This is consistent with the non-symmetric structure of the surface species and with the presence of the silica surface as a ligand, which can significantly affect the chemical shift of these nuclei in a non-homogeneous way. The other main off-diagonal interaction observed on the spectrum implies nuclei resonating around 7.3 ppm and 1.6 ppm. This corresponds to the interaction between the non-*ortho* pyridine protons and one or more CMe groups, most probably within the same [N,O] framework, an assignment in agreement with the chemical shifts of these signals. Accordingly, when comparing distances in the X-ray crystal structure (Figure 1 and Table 1), the C13-*H*–C16-*H* distance is of 2.332 Å, which is similar to the C13-*H*–C12-*H* distance (2.336 Å). Off-diagonal correlations for the $NMe_2$ groups are not observed on the 2D spectrum. The more rigid character of the [N,O] chelating ligand implies that the $CMe_2$ groups are less mobile than the $NMe_2$ groups, which thereby enhances the dipolar interactions, and thus increases their sensitivity to the double quantum correlation experiment compared to the dimethylamido protons. When using the two rotor periods BABA excitation, and thus probing longer interaction ranges, another off-diagonal correlation was observed between signals at 9 ppm and 1.6 ppm (Figure 7). This corresponds to *ortho* pyridine protons interacting with a C*Me* group, and, more precisely, with the same CMe which correlates with the non-*ortho* pyridine protons (this interaction is of course also visible on the spectrum). This correlation most probably implies protons located on two different [N,O] ligands on the same grafted species. Indeed, on the X-ray structure of **3**, the C10-*H*–C16$^2$-*H* distance is of 2.510 Å (inter-ligand interaction), much shorter than C10-*H*–C16-*H* or C10-*H*–C19-*H* distances of 5.434 and 4.730 Å, respectively (intra-ligand interaction).

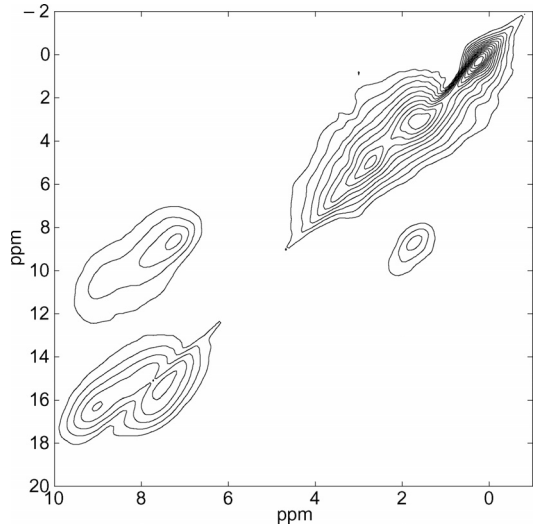

Figure 7. $^1$H 2D double quantum MAS spectrum of **4** using excitation/reconversion pulse train of two rotor periods (100 μs) (800.13 MHz, 20 kHz spinning speed, pulse RF = 80 kHz).

$^{13}$C CP MAS NMR signals are reminiscent of those of the molecular precursor (Figure 8). Signals of the pyridine carbons appear at 171.8, 150.0, 135.9, and 119.3 ppm. The $CMe_2$ groups give rise to signals at $\delta$ = 84.1 and 81.7 ppm for two different types of *C*$Me_2$, and to a broad signal centered at $\delta$ = 30.5 ppm for the methyl groups. Two other peaks are observed at $\delta$ = 57.9 and 48.2 ppm, a range corresponding to WN*Me* groups. Indeed, the $^{13}$C CP MAS NMR spectrum of ≡Si–O–[$W_2(NMe_2)_5$] comprises three peaks at $\delta$ = 58.2, 47.8, and 37.6 ppm.[9] Other WN*Me* signals may be hidden under the broad peak centered at $\delta$ =

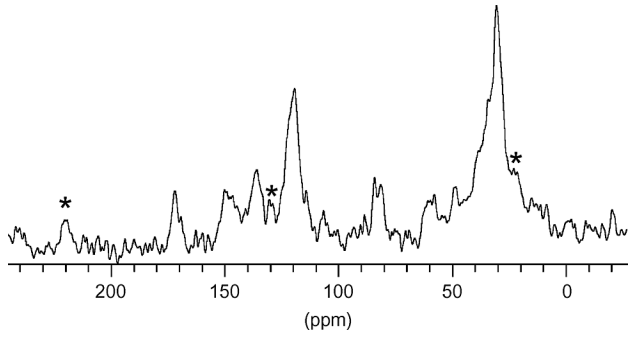

Figure 8. $^{13}$C CP MAS spectrum of **4** (100.6 MHz; * denotes rotation peaks).

30.5 ppm. Again, the high number of C*Me* and N*Me* signals is consistent with the low symmetry of the grafted species.

The reactivity of **4** toward alkyne metathesis was probed. Unfortunately, this material proved to be inactive toward 4-nonyne, giving no metathesis products in detectable quantities under the conditions used for **3** (see above).

## Conclusions

The synthesis of a dinuclear tungsten(III) complex bearing pyridylalkoxido and amido ligands has been accomplished through alcoholysis of the hexakis-amido ditungsten derivative. The controlled grafting of this compound has been successfully carried out, as shown by several characterization techniques. The reactivity spectrum of the molecular compound and of its grafted analogue in alkyne metathesis is narrow; only the coordination complex displays (modest) activity, under very specific conditions. The blocking of a coordination site by the pyridine nitrogen may be at the origin of the lack of reactivity of the $W_2$ core, by preventing access to reactive sites of the metallic species (W–N and W≡W bonds). Thus, in this case, the hemilabile character of the studied ligand may not be sufficient to perform its ascribed role, as in the case of the methoxy-substituted derivatives. Future efforts in catalyst design are in progress, aimed at introducing less coordinating functions on the alkoxide ligands.

## Experimental Section

**General Procedures:** All experiments were performed under argon using standard Schlenk techniques or in a M-Braun glove-box, with rigorous exclusion of traces of moisture and air. THF, benzene, toluene, and hexane were purified by distillation from sodium/benzophenone ketyl and were stored over activated 4-Å molecular sieves. $[W_2(NMe_2)_6]$ was synthesized by following the literature procedure.[22] The silica support (Aerosil 380 silica, Degussa, specific area 380 $m^2 g^{-1}$) was heated under $10^{-6}$ mbar at 500 °C for 15 h then at 700 °C for 4 h. Elemental analyses were performed in the Service Central d'Analyses du CNRS (tungsten) and in the LSEO, University of Bourgogne (C,H,N). DRIFT spectra were recorded with a Nicolet Protégé 460 equipped with an MCT detector and a Harrick analysis chamber, with a resolution of 4 $cm^{-1}$. NMR liquid-phase spectra were recorded with Bruker Avance 300 and Avance 400 spectrometers at 298 K, unless specified otherwise. NMR (solid-state) spectra were recorded with a Bruker Avance 400 ($^1$H: 400.1 MHz, $^{13}$C: 100.6 MHz) and Avance II 800 ($^1$H: 800.13 MHz). The $^1$H-$^{13}$C CP experiments were obtained at a spinning frequency of 10 kHz, with a recycle delay of 5 s and 10240 scans were collected. For the CP step, a ramped radio-frequency (RF) field centered at 50 kHz was applied on protons, while the carbon RF field was matched to obtain an optimum signal. The contact time was set to 1.5 ms for the $^{13}$C CP experiment. 2D Double Quantum Magic-Angle Spinning spectra were performed at 20 kHz spinning speed on a 18.8 T Avance II Bruker spectrometer (Larmor frequency 800.13 MHz). 2Q coherences were created using the BABA[21] scheme with mixing times of one (50 μs) or two (100 μs) rotor periods and an 80 kHz RF field. Chemical shifts for $^1$H and $^{13}$C NMR spectra are reported relative to TMS. Gas chromatography analyses were performed with a Chrompack CP9001 gas chromatograph under $N_2$ flow with a CPSil 8 CB column (15 m length, 0.32 mm diameter, 0.25 μm film thickness). Deconvolution was performed using the dmfit program.[23]

**Synthesis of $[W_2\{(2\text{-pyr})C(Me_2)_2O\}_2(NMe_2)_4]$ (3):** To a solution of $[W_2(NMe_2)_6]$ (101 mg, 0.16 mmol) in toluene (10 mL) was added a solution of 2-(2-pyridyl)propan-2-ol (260 mg, 1.9 mmol) in toluene (5 mL). The reaction mixture was stirred for 16 h at room temperature during which the solution turned deep red. All volatile compounds were removed under vacuum and the resulting red solid was heated to 60 °C under vacuum ($10^{-2}$ mbar). The red residue was washed with a small portion of pentane where it is only slightly soluble. The product was obtained as a red powder in 40% yield. Crystals suitable for X-ray analysis were grown in pentane. $C_{24}H_{44}N_6O_2W_2$ (816.3): calcd. C 35.31, H 5.43; found C 35.27, H 5.81. $^1$H NMR (300 MHz, [D$_6$]benzene): $\delta$ = 9.04 [dt, $^3J$(H-H) = 5.4, $^4J$(H-H) = 0.7 Hz, 2 H, 6-H pyr], 6.52 [dt, $^3J$(H-H) = 7.6, $^4J$(H-H) = 1.5 Hz, 2 H, 4-H pyr], 6.28 [ddd, $^3J$(H-H) = 7.1, $^3J$(H-H) = 5.6, $^4J$(H-H) = 1.3 Hz, 2 H, 5-H pyr], 6.20 [dt, $^3J$(H-H) = 7.8, $^4J$(H-H) = 1.0 Hz, 2 H, 3-H pyr], 4.73 (s, broad, 6 H, N$^1$*Me*Me), 3.70 (s, 12 H, N$^2$Me$_2$), 2.28 (s, broad, 6 H, N$^1$Me*Me*), 1.75 (s, 6 H, C*Me*Me), 1.04 (s, 6 H, CMe*Me*) ppm. $^{13}$C{$^1$H} NMR (100 MHz, [D$_8$]toluene, 283 K): $\delta$ = 171.60 (C-2 pyr), 150.11 (C-3 pyr), 135.38 (C-4 pyr), 121.05 (C-5, pyr), 118.26 (C-6 pyr), 80.90 (*C*Me$_2$), 57.78 (broad, NMe), 51.38 (broad, NMe), 43.23 (broad, NMe), 38.60 (C*Me*), 33.36 (C*Me*) ppm. IR [diffuse reflectance]: $\tilde{\nu}$ = 3103 (w), 3078 (w), 3055 (w), 3029 (w), 3001 (w), 2983 (m), 2969 (m), 2955 (m), 2942 (m), 2916 (m), 2846 (s), 2810 (s), 2768 (m), 2755 (s), 2708 (w), 1652 (w), 1631 (w), 1600 (w), 1567 (w), 1546 (w), 1542 (w), 1533 (w), 1475 (m), 1448 (m), 1435 (m), 1414 (w), 1395 (w), 1369 (m), 1347 (m), 1294 (m), 1273 (m), 1245 (s), 1214 (w), 1185 (s), 1155 (s), 1122 (s), 1099 (m), 1078 (m), 1053 (s), 1018 (m), 995 (s), 964 (s), 958 (s), 947 (s), 909 (w), 886 (m), 874 (w), 805 (w), 777 (s), 758 (s), 739 (w), 696 (w), 672 (w), 648 (m), 614 (s), 561 (s), 553 (m), 546 (m), 538 (m), 531 (w), 524 (m), 511 (w), 500 (w), 495 (w), 487 (w) $cm^{-1}$.

**Synthesis of Material 4:** To a suspension of $SiO_2$-700 (116 mg) in pentane (4 mL) was added a solution of **3** (35 mg, $43.10^{-6}$ mol) in pentane (4 mL). The silica rapidly turned to deep red-brown while the supernatant gradually lost its color. After overnight stirring at room temperature, the red-brown solid was separated by filtration, washed with pentane (3 × 8 mL), and dried under vacuum ($10^{-6}$ mbar) to afford 149 mg of **4** as a deep red-brown powder. Elemental analysis (%): C 8.41, H 1.20, N 1.97, W 10.53. IR (diffuse reflectance): $\tilde{\nu}$ = 3081 (w), 3065 (w), 2974 (m), 2923 (m), 2896 (m), 2858 (m), 2816 (m), 2769 (m), 2711 (w), 1607 (m), 1568 (m), 1477 (m), 1568 (m), 1477 (s), 1419 (s), 1375 (s), 1355 (s) $cm^{-1}$. $^1$H MAS (400 MHz): $\delta$ = 9.4 (sh), 7.07, 4.3, 2.07, 1.20, 0.00 ppm. $^{13}$C CP-MAS (100.6 MHz): $\delta$ = 171.8, 150.0, 135.9, 130.4, 119.3, 84.1, 81.7, 57.9, 48.4, 30.5 ppm.

**Catalytic Investigations:** A Schlenk tube was charged with 4-nonyne (1.45 mmol), decane (0.1 mL), and toluene (5 mL), affording solution **A**, and was then heated to 363 K. A second Schlenk tube was charged with **3** (0.0254 mmol), alcohol (0.101 mmol), toluene (1 mL), and was stirred at room temperature for 10 min affording solution **B**. Solution **B** was then injected to solution **A** at 363 K. The reaction was stopped after 1 h by injection of methanol and exposition to air. Conversion and selectivity were measured by GC analysis using decane as the internal standard. Alcohols used for these tests were *tert*-butyl alcohol, 3-quinuclidinol, 1-adamandanol, and phenol.

**X-ray Structural Analysis of 3:** Crystal and refinement data are summarized in Table 3. X-ray data were collected with a Bruker SMART CCD area-detector diffractometer with Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å) at $T$ = 100 K. The structure was solved by direct methods.[24] Refinement against $F^2$ was performed by SHELX-97 with anisotropic temperature factors for non-hydrogen atoms and protons at geometrically calculated positions as riding atoms. Residuals in the final Fourier-difference map are probably due to imperfect absorption corrections.

# Flexible $Cu^{I}$–Thiolate Clusters with Relevance to Metallothioneins

**Biplab K. Maiti,[a] Kuntal Pal,[a] and Sabyasachi Sarkar*[a]**

**Keywords:** Metallothioneins / Flexibility / Coordination modes / Copper / Sulfur / Photoluminescence

Simple Cu–thiolate chemistry was developed to demonstrate the presence of copper clusters with $\{Cu_4S_6\}$, $\{Cu_5S_7\}$ and $\{Cu_6S_4\}$ cores in relevance to copper-containing metallothioneins. The new hexanuclear tricoordinate triply bridging thiolatocopper(I) clusters $[NEt_4]_4[Cu_6(SPh)_4Cl_6]$ (**1**) and $[NEt_4]_4[Cu_6(SPh)_4Br_6]$ (**2**) were synthesized from the soup of polymeric $[Cu^{I}SPh]_n$ and quaternary ammonium halide. These complexes readily converted into $[Et_4N]_2[Cu_5(SPh)_7]$ (**3**) and $[Et_4N]_2[Cu_4(SPh)_6]$ (**4**) in the presence of excess amounts of thiol. All are structurally characterized by single-crystal X-ray crystallography and these smaller clusters may be inscribed into the structurally characterized larger cluster $\{Cu_8S_{10}\}$ obtained from synthetic copper yeast metallothioneins. Like Cu–MT proteins, all these clusters show photoluminescence around 560 nm on excitation at 350 nm, and these emission spectra are completely quenched by molecular oxygen. Variable copper stoichiometry and the interconversion of only monodentate thiolate ligands in these clusters convey the importance of flexibility, which is relevant to metallothioneins.

## Introduction

Intracellular copper is transiently associated with small copper-binding proteins as copper chaperones that distribute copper to specific intracellular destinations and to metallothioneins (MT). MT is a class of low molecular weight cysteine rich proteins that generally shuffle essential metal ions like copper and zinc in biosystems, and they are present in all animal phyla as well as in certain fungi, plants and cyanobacteria.[1–7] The protection of cells against toxic metal ions through the process of sequestration is another role played by these proteins. MT proteins from varied species showed to share a particular set of sequence-specific characters with the consensus sequence -CxCxxxxCxC- and -CxCxxxxxCxC- motifs.[8] These four cysteine units may thus be used to complex copper ions besides other cysteine moieties located differently in apo-MT proteins. In Cu–MT coordination chemistry, the $Cu^{I}$/protein stoichiometry is varied because of the diverse functions of copper, such as acquisition, metabolism, storage and transport. Among these, in vitro synthesized N.crassa MT was shown to provide flexible polypeptide folds that may be influenced by the variable coordination number of copper, which results from metal–thiolate clusters with varied stoichiometries, such as $Cu_4(CysS)_7$($Cu_4$–NcMT) or $Cu_6(CysS)_7$($Cu_6$–NcMT).[8] A neuronal growth inhibitory factor, metallothionein-3, was shown to contain the $Cu_4(CysS)_9$ ($Cu_4$-humanMT-3) cluster located in the N-terminal β-domain of the protein, which can further be loaded with copper to yield a $Cu_6(CysS)_9$ cluster.[9] The isolation of a synthesized $Cu_8(CysS)_{10}$($Cu_8$-yeastMT) cluster is thought to crystallize from a solution of $Cu_7$-yeastMT, which leaves the $Cu_6$ cluster in solution.[10] In contrast to zinc, which normally retains a tetrahedral coordination, the ready adaptation of $Cu^{I}$ to diagonal, trigonal or tetrahedral coordination geometries has made the chemistry of Cu–MT diverse and interesting. In the large $Cu_8$–$S_{10}$ cluster, the only two diagonal Cu binding sites are thought to be responsible for trafficking copper in biological systems, and this ability is attributable to the labile bonding of these two copper atoms.[10,11] Prediction of the formulation of the copper–thiolate cluster is also hindered by the ability of the sulfur atom of the cysteinyl moiety to link the bridging ligand in a $\mu_2$-S or $\mu_3$-S fashion. Furthermore, the possibility of a large degree of folding in the protein may account for the structural interplay of these copper clusters. Among the common $Cu_n$ clusters ($n$ = 4,[12] 6,[8,9] 7[13] and 8[10,11]) known to be present in Cu–MT, the varied ligation number of the thiolate ion ($CysS_m$, $m$ = 4 to 11) contributes to the diverse stoichiometry that one can anticipate in Cu–MT clusters. Accordingly, many examples of monodentate thiolatocopper(I) clusters have been reported so far by X-ray crystallography[14–16] [$CuS_2$,[17] $CuS_3$,[18,19] $Cu_2S_2$,[20] $Cu_3S_3$,[21] $Cu_4S_4$,[22] $Cu_4S_6$,[18,23–26] $Cu_5S_6$,[27,28] $Cu_5S_7$,[29] $Cu_6S_4$ (in this work) $Cu_7S_8$,[30] $Cu_8S_8$[31] and $Cu_{12}S_{12}$[32]].

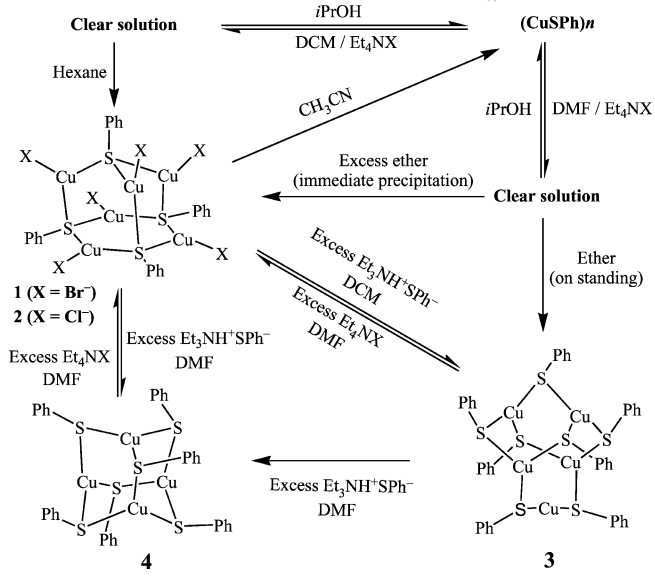
On the basis of this principle, we allowed the free assembly of discrete copper(I)–thiolate clusters from the soup of polymeric $[Cu^ISPh]_n$[33] and quaternary ammonium halide in the presence or absence of an excess amount of thiolate ions. We report herein the first synthesis of the hexanuclear tricoordinate triply bridging thiolatocopper(I) clusters $[NEt_4]_4[Cu_6(SPh)_4Cl_6]$ (**1**) and $[NEt_4]_4[Cu_6(SPh)_4Br_6]$ (**2**). They were characterized by X-ray crystallography as well as by spectroscopic methods, including UV/Vis and luminescence, and their ready interconversion with $[Et_4N]_2[Cu_5(SPh)_7]$ (**3**) and $[Et_4N]_2[Cu_4(SPh)_6]$ (**4**). All these smaller clusters may be inscribed into the structurally characterized larger cluster $\{Cu_8S_{10}\}$ obtained from the synthesized copper yeast metallothioneins. From a synthetic analogue approach, the present study is based on the filling of this gap to achieve this specific cluster arrangement.



Scheme 1. The facile interconversion of $Cu_4$-, $Cu_5$- and $Cu_6$ clusters.

## Results and Discussion

### Synthesis

$Cu^I$–thiolate clusters are known and earlier synthetic strategies generally involved the use of $Cu^{II}$ ions to exploit the reducing power of the thiolate group used as a ligand. This synthetic protocol led to the formation of a mixture of products such as $[Me_4N]_2$ salt of **3** and **4**[34] and both were crystallized out. In another procedure, the use of $Cu^I$ as the source material was made and this was treated with KSPh in acetonitrile and the $[PPh_4]_2$ salt of **4**[18] was isolated. Alternatively, $[PPh_4]_2[Cu(SPh)_3]$[18] was treated with $[Cu(CH_3CN)_4]ClO_4{\cdot}2H_2O$ in boiling acetonitrile to synthesize the same compound, but the yield of the product in these procedures was not reported. In the present work, our intention was to understand the solubility of the Cu–thiolate polymer in the form of isolable discrete cluster anions as quaternary ammonium ion salts in the presence or absence of an excess amount of thiolate ions. The hexanuclear copper(I)–thiolate complexes having $Cu_6S_4X_6$ (X = $Cl^-$ and $Br^-$) (Scheme 1) were synthesized by treating $(CuSPh)_n$[33] with the respective quaternary ammonium halide salt ($Et_4NX$) in a 1:1 molar ratio of CuSPh/$Et_4NX$ to produce **1** and **2** as block-shaped colourless crystals in high yield.

By changing the reaction medium and by performing the reaction in the presence of available thiolate ions, the synthesis of **3** and **4** and the mutual interconversion of all four (**1**–**4**) of these discrete clusters was followed by electronic spectroscopy as shown in Figure S1 (Supporting Information). Our attempt to increase the ligation of the thiolate ions by metathesis of **1** or **2** by anticipating the formation of $\{Cu_6(SPh)_{10}\}$ in light of attaining maximum thiolate ligation similar to those reported in the MT proteins was thwarted by the isolation of **3** and **4** instead. Compound **3** was synthesized by the reaction of CuSPh with $Et_4NCl$ in a 1:1 molar ratio in DMF as bright-yellow needle-shaped crystals in high yield. It is noteworthy that **3** crystallized out of solution on standing after the addition of diethyl ether. In contrast, the addition of an excess amount of diethyl ether caused rapid precipitation of the $Cu_6$ cluster instead. The reactions of **1** or **2** with excess amounts of thiolate ions afforded solvent-dependent formation of **3** and **4** in almost quantitative yields. In less polar solvents, such as DCM, the reaction of **1** or **2** with an excess amount of thiolate afforded **3**, whereas in more polar solvents, such as DMF, the reaction led to the formation of **4**. It was found that the transformation of **1** into **3** was very facile in the reverse direction. The reversal of **4** to **1** or **2** may also readily be achieved by the addition of an excess amount of countercation in DMF, but **3** may be converted irreversibly into **4** in DMF. Compounds **1** and **2** in $CH_3CN$, and in any other protic solvent, decompose with the precipitation of insoluble $(CuSPh)_n$[33] and the release of $[Et_4N]X$ (X = Cl and Br) into the solution. The interconversion between these compounds is dependent on the solvent used and on the Cu/S ratio. The Cu/S ratio in Cu–MT may be affected by the surrounding environment or even by a variation in the cysteine content of the peptide; however, it is important to note that the availability of Cu is the key factor affecting the stoichiometry of the Cu/S clusters in MT. All these compounds, when present in solution, are susceptible to aerial oxidation, which leads to decomposition. Even in the solid state, surface oxidation of **1** or **2** is noticed on exposure to air, and the surface turns from pure white to white with a greenish tinge. EPR response of this reaction clearly indicates that EPR inactive $Cu^I$ is oxidized to EPR active $Cu^{II}$.

### Description of Structures

Suitable diffraction quality single crystals of all the reported complexes were made according to the procedure described in the corresponding synthesis section. Details of the crystallographic data collection and refinement parameters are provided in Table 3.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Crystals of chloro and bromo compounds **1** and **2**, respectively, are isostructural, triclinic, $P\bar{1}$ and have the same number of formula units ($Z = 2$) in each unit cell of very similar dimensions. Complexes **1** and **2** exhibit a $Cu_6S_4X_6$ core (Figure 1), which is constructed from the aggregation of six $Cu^I$ centres, six halide (Cl or Br) atoms and four S (benzenethiolate) atoms.

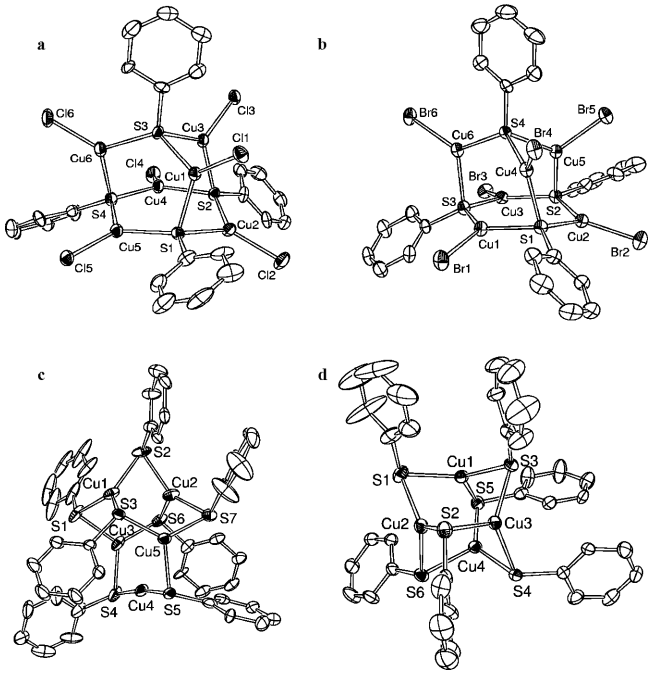


Figure 1. The structure (ORTEP view) of the complex anion of (a) **1**; (b) **2**; (c) **3** and (d) **4**. The atomic numbering scheme is shown and the thermal ellipsoids are drawn at the 50% probability level; hydrogen atoms have been omitted for clarity.

Compounds **1** or **2** can be divided into two segments to form one $Cu_3S_3X_3$ unit (bottom segment) and one $Cu_3SX_3$ unit (top segment) (atoms labelled with superscript b and t, respectively). These two units are bound by the S atom of the thiolate that bridges two Cu atoms in $Cu^b{}_3S^b{}_3$ and is bound to the Cu atom in $Cu^t{}_3S^t$. The top $S^t$Ph ligand is directed axially and is perpendicular to the virtual $Cu^t{}_3$ plane. Each copper atom in the top is three coordinate and forms bonds from one S atom and one halogen atom in the same segment and one S atom from the bottom segment. In this way, a core is formed that comprises a fused six-membered $Cu_3S_3$ ring: one for the bottom (almost planar hexagon) and three for the side faces (pseudochair configuration). Each copper atom in the bottom is three coordinate with bonds from two S atoms and one halogen atom in the same segment, and these $S^b$Ph ligands are around the equatorial girdle and form a virtual $Cu^b{}_3$ plane. The two $Cu_3$ triangle bases are oriented face-to-face and are rotated by ca. 45°. Each copper centre in the cluster adopts an approximately trigonal planar geometry, and it is coordinated to two thiolate ligands and a halide ion. The mean angle at the coordinated copper is 119.75(7)° for **1** and 119.95(6)° for **2**, which suggests an almost trigonal planar geometry of the copper centre in these complexes. Each sulfur atom of the phenylthiolate ligand within the cluster adopts an approximate tetrahedral geometry that coordinates three trigonally coordinated copper atoms (triply bridging thiolate ligand). The Cu–S bond lengths [mean 2.2465(17) Å for **1** and mean 2.2502(18) Å for **2**][35] are dependent on the coordination number of the copper atom and distinct ranges can be distinguished: 2.14–2.17 Å for two coordinate[29,36] copper atoms, 2.22–2.23 Å for three coordinate[18,23–26,37] copper atoms and 2.33–2.48 Å for four coordinate[38–40] copper atoms, and the Cu···Cu separations range from 2.8622(12) to 4.0699(13) Å for **1** and from 2.8242(13) to 4.0557(13) Å for **2**. Bond lengths and angles are listed in Table 1.

The type of $Cu_4S_6$ and $Cu_5S_7$ core[18,23,26,29] observed for **3** and **4** (Figure 1), respectively, were structurally characterized previously for monodentate S donor ligands in $[Cu_4(SPh)_6]^{2-}$ and $[Cu_5(SPh)_7]^{2-}$ with $[Me_4N]$ and $[PPh_4]$ salts, and the dimension of these cores as $[Et_4N]$ salts are detailed in Table 3. Complexes **1**, **2** and **4** possess tricoordinated copper; in **1** and **2** $\mu_3$-SPh bridging exists, whereas in **4**, $\mu_2$-SPh bridging is present. Unlike **1**, **2** or **4**, compound **3** possesses both tri- and bicoordinated copper but with only a $\mu_2$-SPh bridging ligand. Similar to **1** or **2**, the Cu–S bonds in Cu–thiolate bridges in **3** or **4** range from 2.159 to 2.309 Å. This may be compared with the Cu–S–Cys bonds in the range from 2.145 to 2.395 Å found in the structurally characterized $Cu_8(CysS)_{10}$ ($Cu_8$-yeastMT) cluster.[10] The $Cu_8(CysS)_{10}$ ($Cu_8$-yeastMT) cluster[10] can be described as two groupings of four copper atoms; both groups have a flattened tetrahedron structure and two of the eight copper atoms are diagonally coordinated and the six others are trigonally coordinated with doubly and triply bridging cysteine moieties, as highlighted in Figure 2.

Structurally characterized clusters **1**, **2**, **3** and **4** may be inscribed within the structurally characterized $Cu_8(CysS)_{10}$ ($Cu_8$-yeastMT) cluster in Figure 2 and comparison of the Cu–S distance in **1**, **2**, **3**, **4** and $Cu_8(CysS)_{10}$ ($Cu_8$-yeastMT) cluster are listed in Table 2. In Figure 2, cluster **4** is placed on the left side (Cu1, Cu2, Cu3 and Cu4) of the larger cluster, $Cu_8(CysS)_{10}$ and **3** are placed on the right side (Cu4, Cu5, Cu6, Cu7 and Cu8) of the larger cluster $Cu_8(CysS)_{10}$, and both share one common copper atom (Cu4). The Cu1 atom of the larger cluster is bonded with S1 and S3 but Cu1 in **4** is tricoordinated with an extra bond to S5. The bicoordinated Cu1 in $Cu_8$-yeastMT is directly related to its labile nature in displaying copper trafficking properties. The two diagonally coordinated copper ions (Cu1 and Cu8) are more labile than other copper atoms in $Cu_8(CysS)_{10}$. In this respect, $Cu_6$ clusters **1** or **2** are more important. In Figure 2, the six copper ions in $Cu_8(CysS)_{10}$ [(Cu2, Cu4 and Cu6) and (Cu3, Cu7 and a missing Cu as shown encircled)] can be described as grouped into two set of three, both of which have planar triangle geometry and linked by sulfur. A closer inspection shows that for $Cu_8$-yeastMT, middle part of the skeleton have similar structural motif of **1** or **2** as shown in Figure 2.

### Electronic and Photoluminescent Spectra

Complexes **1** and **2** are colourless and display featureless electronic spectra with a strong absorption in the UV region. As shown in Figure 3, the UV/Vis absorption spectrum of **1** in DCM showed a strong absorption centred at $\lambda_{max}$ = 272 nm ($\varepsilon$ = 27800 $M^{-1}cm^{-1}$). Likewise, the absorption spectrum for complex **2** is similar: $\lambda_{max}$ = 266 nm ($\varepsilon$ = 33100 $M^{-1}cm^{-1}$).

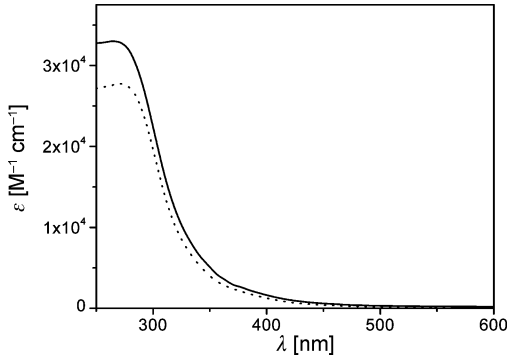

Figure 3. Absorption spectra of complex **1** (broken line) and **2** (solid line) at room temperature in DCM.

Excitation spectra of solid samples of hexanuclear copper(I) complexes **1** and **2** are shown in Figure 4. Compound **2** exhibits a broad excitation band centred at $\lambda_{ex}$ = 346 nm with a weak shoulder at 425 nm, whereas an intense band is observed at $\lambda_{ex}$ = 346 nm for corresponding solid complex **1**.

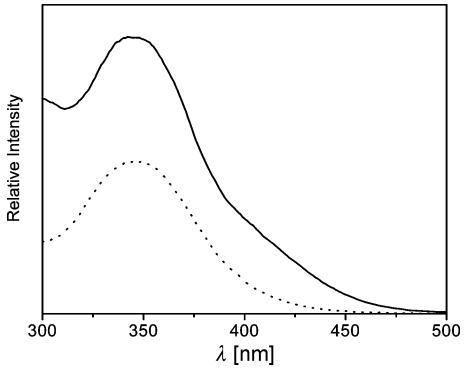

Figure 4. Excitation spectra of **1** (broken line) and **2** (solid line) at room temperature in the solid state.

Photoluminescence is a powerful tool to investigate the structural information of Cu–MTs because of the characteristic luminescence properties of the $Cu^I$–thiolate clusters. Complexes **1** to **4** display photoluminescence like other copper–sulfur clusters.[41,42] Compounds **1**, **2** and **3** each exhibit an intense emission band in the range 555–573 nm (excitation at 350 nm), whereas under identical conditions, a very weak emission at 572 nm (excitation at 350 nm) was observed from **4** (Figure 5). Possible assignment of transition is considered as: (1) ligand-to-metal CT (LMCT), (2) the halide-to-metal CT (XMCT), (3) transition in Cu cluster (CC–MOs), (4) halide-to-ligand CT (XLCT) and (5) $Cu^I$ d–s transition.

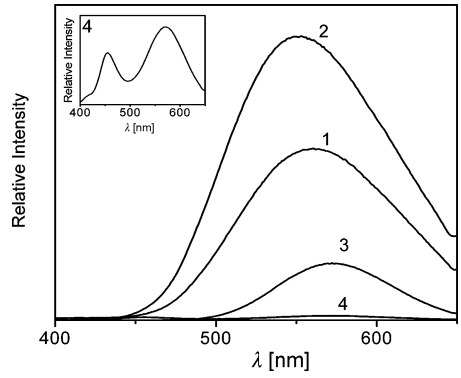

Figure 5. Emission spectra of **1** (560 nm), **2** (555 nm), **3** (573 nm) and **4** (572 nm) at room temperature in the solid state (excitation at 350 nm); inset: the emission spectra of **4** in relatively enlarged scale of intensity.

From a structural viewpoint, cluster **1** and **2** ($Cu_6$ cluster) both have long Cu···Cu separations (>2.8 Å). So, transition in Cu clusters (CC–MOs) does not contribute in the emission spectra. However, the charge-transfer emission band depends on the metal coordination ligand. Given the strong electron-donating ability of the thiolate ligand, it is expected that the origin of the emission is due to thiolate–copper(I) (LMCT) transition. Contributions like XMCT and XLCT may be minor, if they exist. The emission spectrum of **4** shows two bands at 436 nm and 572 nm. The low-energy emission band is attributed to thiolate–copper(I) (LMCT) transition and the high-energy band to CC origin (the Cu···Cu separation <2.8 Å). Compound **3** exhibits an emission band at 573 nm, which may originate from LMCT states in accord with the electron-donating ability of the thiolate ligands. The observed differential emission intensity must be based on the cluster size and the Cu/S stoichiometry. The loss in intensity of **1** than **2** is due to some oxidation of $Cu^I$ to $Cu^{II}$ during (see latter) isolation in atmospheric air. The Cu–MT proteins have been found to exhibit significant luminescence,[43–45] which is related to the $Cu^I$–thiolate chromophore and Cu–S protein emission lies from 580–700 nm at room temperature. Like Cu–MT proteins, clusters **1**–**4** show photoluminescence in the region around 560 nm on excitation at 350 nm (Figure 5). Interestingly, such emission property can help to identify the Cu/thiol stoichiometry in apo-NcMT proteins.[8] However, with the option of varying the ability of

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

complexation of $Cu^I$ with the overall sulfahydryl groups present in such proteins, the intensity of the emission spectra may be deceptive to extract the actual stoichiometry of the Cu–MT proteins. The difference in Cu/MT stoichiometry in such reconstitution by using apo-NcMT and Zn–NcMT is noteworthy to reflect the possibility in the use of different sulfahydryl groups based on the flexibility of the MT. Complex **1** is found to be more oxygen sensitive and even in the solid its white surface slowly developed a greenish tinge and displayed the appearance of EPR-active $Cu^{II}$ concomitant to the quenching of the emission around 560 nm (Figure 6).

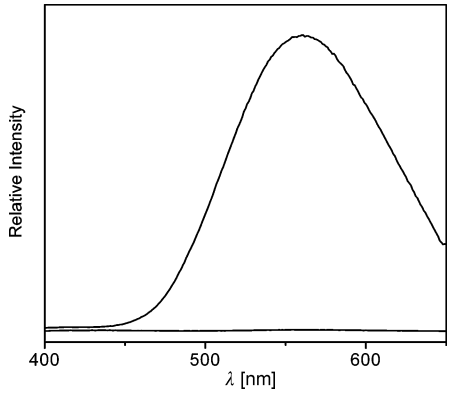

Figure 6. Emission spectra of **1** in the solid state at room temperature: (a) freshly prepared; (b) after 24 h exposure to air.

## Conclusions

We demonstrated the facile interconversion of Cu–SPh clusters with different stoichiometries in relation to the flexibility of MT proteins. The structural variations in these synthesized clusters in solution clearly demonstrate their ability to shuffle copper ions interplaying the overall coordinating ability of the copper cluster, which is not dependent on the nature of the bridging thiolate ion.[46–48] It is to be noted that in the synthesized $Cu_8$-yeastMT cluster[10] or in $Cu_7$-saccharomyces cerevisiae,[12] the presence of the $Cu_6$ cluster is predicted because of the loose coordination of the terminal copper ions. Interestingly, the Cu–S–Cys bond (2.144 Å) between Cu44 and Cys7 is one of the shortest Cu–S–Cys bonds present in the $Cu_8$-yeastMT cluster,[10] but this bond is readily broken and loses the Cu44 ion in solution. This is due to the exposure of this end of the cluster to solvent where this copper can be readily dissociated in solution.[10] We also demonstrated that such copper ion shuffling is possible with a change in solvent under ambient conditions. The Cu/S ratio in Cu–MT can be affected by the surrounding environment or even be variations in the cysteine content; however, it is important to note that the availability of Cu is the key factor affecting the stoichiometry of the Cu/S clusters in MT. The well-known complexity of copper(I)–thiolates is greatly enhanced when moving towards the cysteine rich copper-metallothioneins, whose flexibility is not only due to the lability of the metal–sulfur bond but also to the mobility of the peptide chain.[10] Thus, variation in the folding in this class of proteins may be related to the uptake and release of a copper ion. The different degree of incorporation of copper ions as observed in identifying $Cu_4$ clusters in direct interaction with copper ions with an apo-MT is in contrast with the formation of a $Cu_6$ cluster formed by the displacement of a zinc ion from Zn–MT[8,49–52] and directly related to structural variations influenced by the coordination of zinc ions subsequent to their displacement by copper ions.

## Experimental Section

**General:** All the reactions were carried out under an inert atmosphere and under ambient conditions. $Et_4NBr$, $Et_4NCl$ and thiophenol were obtained from standard commercial sources. Solvents were distilled and dried by standard procedure. Elemental analyses for carbon, hydrogen, nitrogen and sulfur analysis were recorded with a Perkin–Elmer 2400 microanalyzer. Electronic spectra were recorded with a Cintra 10 UV/Vis spectrophotometer. The emission spectra were recorded with a fluorolog fluorescence spectrophotometer. EPR spectra were measured with a Varian E-109 and with a Bruker EMX X-band EPR spectrometer at room temperature in solid sample. NMR spectra were recorded with a JEOL JNM-LA 400 FT–NMR machine. $[Cu^ISPh]_n$ was prepared by a literature procedure.[33]

**$[Et_4N]_4[Cu_6(SPh)_4Cl_6]$ (1):** To a suspension of polymeric $[Cu^ISPh]_n$ (0.34 g, 2 mmol) in DMF (25 mL) was added $Et_4NCl$ (0.49 g, 3 mmol). The mixture was stirred at room temperature to afford a clear-yellow solution within 10 min. An excess amount of diethyl ether (≈ 100 mL) was added to precipitate the light yellow product and this was separated by filtration, washed with 2-propanol to remove any unreacted $Et_4NCl$ followed by diethyl ether and vacuum dried. Compound **1** was crystallized by dissolving it in DCM and by adding hexane and was isolated as colourless blocks. The crystal when free from solvent is very susceptible to loose coordinated solvent molecules, which results in opacity and brittle crystals. Freshly isolated transparent crystals on dissolution in DMSO decomposed to release $Et_4NCl$ and the solvent in the lattice. Yield: 0.38 g (75%). $^1H$ NMR (400 MHz, [D$_6$]DMSO): $\delta$ = 1.154 (t, $J$ = 7.1 Hz, 3 H, $CH_3$), 3.199 (q, $J$ = 7.1 Hz, 2 H, $CH_2$), 5.731 (s, 2 H) ppm. NMR showed the presence of $CH_2Cl_2$; proton integration provided roughly $1.5CH_2Cl_2$ per molecule of the complex. $C_{56}H_{100}Cl_6Cu_6N_4S_4$ (1551.69): calcd. C 43.31, H 6.44, N 3.61, S 8.25; found C 43.45, H 6.62, N 3.57, S 8.23.

**$[Et_4N]_4[Cu_6(SPh)_4Br_6]$ (2)**

**Method 1:** A procedure similar to that described for the synthesis of **1** was carried out with $Et_4NBr$ (0.66 g, 3 mmol) in place of $Et_4NCl$ to afford a light yellow precipitate. Compound **2** crystallized from DCM/hexane as colourless blocks. Yield: 0.48 g (80%).

**Method 2:** To a solution of **3** (0.34 g, 0.25 mmol) in DMF (25 mL) was added an excess amount of $Et_4NBr$. The mixture was stirred to afford a light yellow solution within 15 min. An excess amount of diethyl ether (≈ 100 mL) was added to precipitate the crude product. This was separated by filtration and washed with 2-propanol to free it from excess $Et_4NBr$. The product was crystallized from DCM/hexane as colourless blocks. The ready loss of solvent for this complex is similar to that observed with **1**. Yield: 0.31 g (65%). $^1H$ NMR (400 MHz, [D$_6$]DMSO): $\delta$ = 1.145 (t, $J$ = 7.1 Hz, 3 H, $CH_3$), 3.192 (q, $J$ = 7.1 Hz, 2 H, $CH_2$), 5.734 (s, 2 H) ppm. NMR showed the presence of $CH_2Cl_2$ and integration provided $1.5CH_2Cl_2$ per molecule of **2**. $C_{56}H_{100}Br_6Cu_6N_4S_4$ (1818.38): calcd. C 36.96, H 5.5, N 3.08, S 7.04; found C 37.02, H 5.68, N 2.99, S 7.01.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

**$[Et_4N]_2[Cu_5(SPh)_7]$ (3)**

**Method 1:** To a solution of **2** (0.45 g, 0.25 mmol) in DCM (25 mL) was added a mixture of HSPh (1 mL) and $Et_3N$ (0.5 mL). The mixture was stirred at room temperature to afford a light-yellow solution. Into this solution was added hexane (15 mL) and on standing overnight at 0 °C bright-yellow crystals had separated out. These were separated by filtration, washed with hexane and dried in vacuo. Yield: 0.27 g (68%).

**Method 2:** To a suspension of $[Cu^{I}SPh]_n$ (0.34 g, 2 mmol) in DMF (25 mL) was added $Et_4NCl$ (0.49 g, 3 mmol). The mixture was stirred at room temperature to afford a clear-yellow solution. Into this solution was added diethyl ether (≈15 mL) and on standing at 0 °C overnight bright-yellow crystals had separated out. Product **3** was separated by filtration, washed with 2-propanol, ether and dried in vacuo. Yield: 0.23 g (62%). $C_{58}H_{75}Cu_5N_2S_7$ (1342.44): calcd. C 51.85, H 5.59, N 2.09, S 16.69; found C 51.82, H 5.57, N 2.06, S 16.66.

**$[Et_4N]_2[Cu_4(SPh)_6]\cdot 0.5C_3H_8O$ (4):** To a solution of **2** (0.45 g, 0.25 mmol) in DMF (25 mL) was added a mixture of HSPh (1 mL) and $Et_3N$ (0.5 mL). The mixture was stirred for 15 min at room temperature to afford a light-yellow solution. Into this solution was added 2-propanol (40 mL) and on standing at 0 °C overnight pale-yellow crystals had separated out. The crystals were separated by filtration, washed with diethyl ether and dried in vacuo. Yield: 0.30 g (70%). $^1$H NMR (400 MHz, [D$_6$]DMSO): $\delta$ = 1.068 (t, $J$ = 5.6 Hz, 3 H, $CH_3$), 3.095 (q, $J$ = 7.1 Hz, 2 H, $CH_2$), 6.7498 (m, 2 H, *p*-Ph), 7.316 (d, $J$ = 6.9 Hz, 2 H, *o*-Ph) ppm. $^{13}$C NMR (100 MHz, [D$_6$]-DMSO): $\delta$ = 7.011 (-$CH_3$), 25.440 (α-C of *i*PrOH), 51.429 (-$CH_2$-), 121.203 (*p*-Ph), 126.781 (*m*-Ph), 132.557 (*o*-Ph), 145.449 (1C-Ph) ppm. On the basis of the integration of the protons from the phenyl and alkyl groups of the main complex, the extra alkyl protons found were assigned to the *i*PrOH molecules present in the lattice. $C_{53.5}H_{74}Cu_4N_2O_{0.5}S_6$ (1199.72): calcd. C 53.51, H 6.17, N 2.33, S 16.00; found C 53.48, H 6.12, N 2.36, S 16.09.

**X-ray Crystallography:** Suitable diffraction quality crystals were obtained from the crystallization procedures described in each synthesis. The crystals used in the analyses were glued to a glass fibre and mounted on a BRUKER SMART APEX diffractometer. The instrument was equipped with CCD area detector and data were collected by using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71069 Å) at low temperature (100 K). All empirical absorption corrections were applied by using the SADABS program. Cell constants were obtained from the least-squares refinement of three-dimensional centroids through the use of CCD recording of narrow $\omega$ rotation frames, completing almost all-reciprocal space in the stated $\theta$ range. All data were collected with SMART 5.628 (BRUKER, 2003), and were integrated with the BRUKER SAINT program. The structure was solved by using SIR97 and refined with the use of SHELXL-97.[53] The space group of those compounds was determined on the basis of the lack of systematic absence and intensity statistics. Full-matrix least-squares/difference Fourier cycles were performed which located the remaining non-hydrogen atoms. All non-hydrogen atoms were refined with anisotropic displacement parameters. Each complex (**1**, **2** and **3**) possesses only one molecule in their respective asymmetric unit. In the asymmetric unit of compound **4**, there are two independent $Cu_4$ units. The additional symmetry for **4** was checked through PLATON.[54,55] Single crystals of complex **4** were grown from three different batches but all these possess similar crystallographic asymmetric unit. Some of the carbon atoms of ethyl groups of tetraethylammonium cation were disordered for **1**, **2**, **3** and **4** and refined with free part instruction by using SHELXL-97. The structures of **1**, **2** and **4** suffered from disordered and unidentified solvent (DCM/Hexane for **1**, **2** and 2-propanol for **4**) in the lattice, which was not included in the refinement but was taken care of by the SQUEEZE-procedure (from PLATON).[54,55] The volumes occupied by the solvent were 1049.5, 1115.6 and 214.4 Å$^3$, respectively; the numbers of electrons per unit cell deduced by SQUEEZE were 139, 146 and 26. All hydrogen atoms were placed in idealized calculated positions and allowed to ride on their corresponding carbon atoms with fixed isotropic contributions. Further information on crystal data, data collection and structure refinement are summarized in Table 3. Disordered solvent molecule of **1** and **2** were squeezed by using PLATON and details of squeeze results were appended to the crystallographic data file. CCDC-616824 to -616827 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# Cationic Gold(I) Phosphanyl Thiolates: Aurophilic Interactions in the Solid State and in Solution

**Federica Balzano,[a] Angela Cuzzola,[a] Pietro Diversi,*[a] Fabio Ghiotto,[b] and Gloria Uccello-Barretta[a]**

**Keywords:** Gold / Sulfur / Thiolates / Aurophilicity / Aggregation / ESI MS / NMR spectroscopy

The aggregation states in solution of gold(I) cationic complexes of the formula $[Au_2(StBu)(L_2)][BF_4]$ (L = $PMe_3$, $PEt_3$, $PtBu_3$, $PPh_3$; $L_2$ = dppm, dppe) were studied by MS (ESI) and DOSY spectroscopy. These compounds are tetranuclear in the solid state with a core of four gold centres bound together by aurophilic interactions and bridging thiolato groups. Some of these tetranuclear systems are maintained intact in solution depending on the phosphane steric properties or denticity.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2007)

## Introduction

It is well known that many gold(I) complexes in the solid state adopt structures in which polynuclear systems are stabilized by the presence of relatively short Au···Au distances (aurophilic interactions).[1] In particular, cationic gold(I) phosphanyl thiolates $[Au_2(SR)(L_2)][BF_4]$ (L = phosphane), prepared by Bruce and coworkers by chemical oxidation of the corresponding neutral phosphanyl thiolates [Au(SR)(L)], exist in the solid state as oligomers; most of these structures have a core of four gold atoms associated by aurophilic interactions.[2] It is not clear if such structures survive in solution or are cleaved to give dinuclear species (there is no conclusive evidence on this point in the literature) (Figure 1). We recently prepared a series of related compounds with the formula $[Au_2(SR)(L_2)][BF_4]$ (R = $CMe_3$, $CH_2CMe_3$, $CH_2CHMe_2$, $CPh_3$; L = $PMe_3$, $PMe_2Ph$, $PMePh_2$, $PPh_3$) and $[Au_2(SR)(dppe)][BF_4]$ [dppe = 1,2-bis(diphenylphosphanyl)ethane] by following the synthetic strategy of Bruce.[3] In the solid state, the aurophilic interactions build up a structure of four gold atoms with pairs of atoms bound by bridging thiolato ligands, which, at least in the cases studied by X-ray analysis, are generally arranged in an almost perfect square or in an unprecedented zig–zag sequence in the case of $[Au_2(StBu)(dppe)][BF_4]$. The correct formulation for these complexes in the solid state is therefore $[Au_4(SR)_2(L_4)][BF_4]_2$.

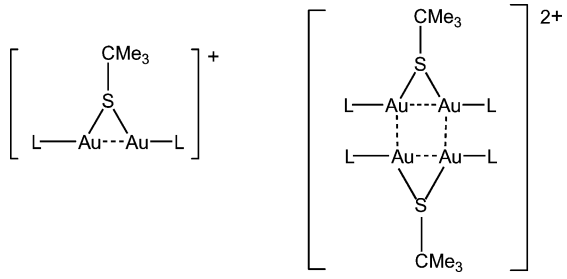

Figure 1. Di- and tetranuclear structural formulae of **2**.

It would be certainly important for a better understanding of the properties and the reactivities of these systems to establish whether the aurophilic interactions unsupported by bridging thiolato groups exist only in the solid state or may survive in the presence of a solvent. Indeed, because of the low energy of such interactions (5–15 kcal mol$^{-1}$),[2e] an equilibrium dimer/monomer can be postulated, which is possibly influenced by the nature of the solvent (polarity, chemical affinity for the metal centre, etc.) and/or the nature of the phosphane and/or thiolato ligands.

In the literature there is only a limited number of studies estimating the presence of aurophilic interactions in solution, and most of them concern $Au^I$–$Au^I$ intramolecular contacts often assisted by the presence of a bidentate phosphane.[4] In these cases, the authors demonstrated the partial survival of the Au–Au bonding interactions by using $^1H$ and $^{31}P$ VT NMR, UV/Vis and EXAFS spectroscopy. There are a few scattered reports also for the study of the intermolecular interactions in solution: the complexes $[Au_2(dppm)(CH_2)_2S(O)NMe_2][BF_4]$ [dppm = 1,1-bis(diphenylphosphanyl)methane], $[Au_2(dmpm)(CH_2)_2S(O)$-

$NMe_2][BF_4]$ [dmpm = 1,1-bis(dimethylphenylphosphanyl)-methane][5] and $\{[(PPh_3)Au]_2Cl\}[SbF_6]$,[6] all of which crystallize as dimers because of the formation of two $Au^I$–$Au^I$ intermolecular bonds, were shown by electronic spectroscopy to maintain at least in part their dimeric structure. Recently, diphosphane gold complexes with Au–Au contacts were studied by EXAFS spectroscopy.[4a]

In consideration of the above, to obtain information on the aggregation state in dissolved cationic phosphanyl thiolates, we began a study of the homogeneous series of gold(I) derivatives with the formula $[Au_2(StBu)(L_2)][BF_4]$ (L = $PMe_3$ **2a**, $PEt_3$ **2b**, $PtBu_3$ **2c**, $PPh_3$ **2d**; $L_2$ = dppm **2e**, dppe **2f**) by using MS (ESI) and DOSY (Diffusion Ordered SpectroscopY). MS (ESI) was recently used for the characterization of supramolecular organometallic assemblies.[7] DOSY NMR techniques, although very promising,[8a,8b] have not attracted much attention so far[8c,8d] for applications in organometallic and inorganic chemistry in solution. Here we report some conclusions obtained during these studies.

## Results and Discussion

### Synthesis

Complexes **2a**–**f** were all prepared by chemical oxidation of corresponding thiolates **1a**–**f** with $[FeCp_2]BF_4$. Compounds **1b**,**c**, **1e**, **2b**,**c** and **2e** have not been reported before, and their preparation and characterization can be found in the Experimental Section. The X-ray structures of **2d**[9] and **2f**[3b] are reported in the literature; for the other thiolates with monodentate phosphanes we assume that they exist in the solid state in the usual four-membered square planar arrangement.

### Mass Spectrometry Studies

The analyses were carried out in methanol solution. As explained above, the gold(I) complexes here investigated may exist in solution as monocationic dinuclear species and/or as dicationic tetranuclear species. The analysis of the isotopic cluster of the molecular ion is crucial to assess the cationic charge: in fact the $[Au_4(StBu)_2(PR_3)_4]^{2+}$ ion, in addition to the peak corresponding to $m/z$ = M/2, presents other minor peaks at $m/z$ = M/2 + $n$/2 ($n$ = 1, 2, 3, etc.) due to the minor isotopes of carbon, sulfur and hydrogen), whereas $[Au_2(StBu)(PR_3)_2]^+$ shows signals at M/2+$n$ ($n$ = 0, 1, 2, 3, etc.). Figures 2–6 report the MS (ESI) spectrum of each complex with the corresponding attributions and the enlargement of the isotopic cluster of the molecular ion.

In the case of **2a**, the isotopic cluster (Figure 2b) is rather resolved and allows us to conclude that the dicationic tetranuclear structure observed in the solid state is largely maintained in solution. The MS–MS spectrum of the molecular ion does not give further information on the aggregation state. However it is interesting to note that, under more severe experimental conditions [declustering potential (*DP*) at 120 V], the isotopic cluster of the molecular peak reveals that the dinuclear species arose at the expense of the tetranuclear species (Figure 2c). The $Au_6$ species responsible for the peak at $m/z$ = 921 most probably formed in the ionization step.

In the case of **2b**, the isotopic cluster is poorly resolved (Figure 3b). It is therefore difficult to draw specific conclusions, but in consideration of the NMR spectroscopic results (vide infra) we suggest that only the dinuclear specie is present in solution. The $m/z$ = 1005 peak may be derived from the aggregation of the dinuclear species during the ionization process. The MS–MS spectrum does not give any additional evidence.

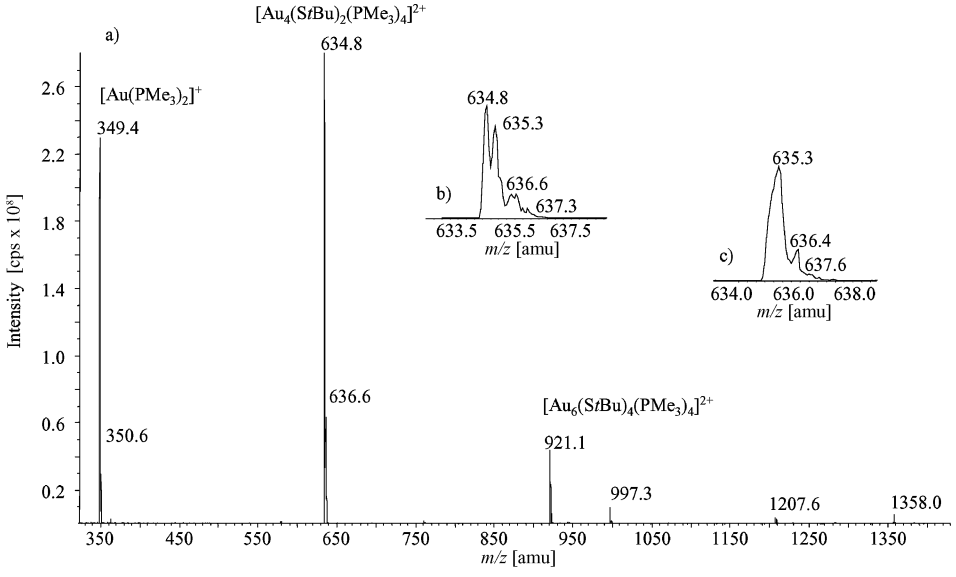

Figure 2. a) MS (ESI+) of **2a**; b) enlargement of the isotopic cluster at $m/z$ = 635 at *DP* = 20 V and c) at *DP* = 120 V.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

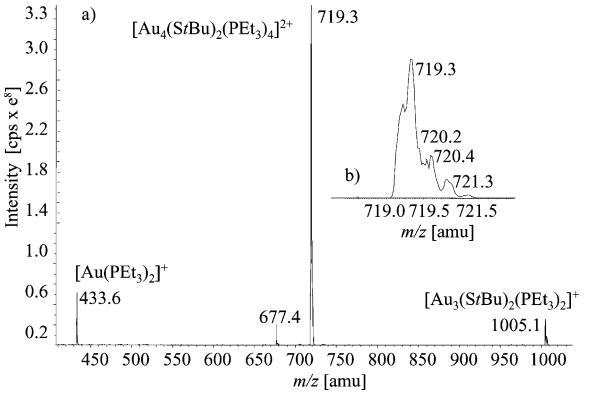

Figure 3. a) MS (ESI+) of **2b**; b) enlargement of the isotopic cluster at *m*/*z* = 719.3.

Alternatively, the mass spectrum recorded for **2c** shows a fairly well-resolved isotopic cluster (Figure 4b), which indicates that only the monocharged dinuclear species is present. The peak at *m*/*z* = 1174 is due to an adduct probably formed during the ionization process.

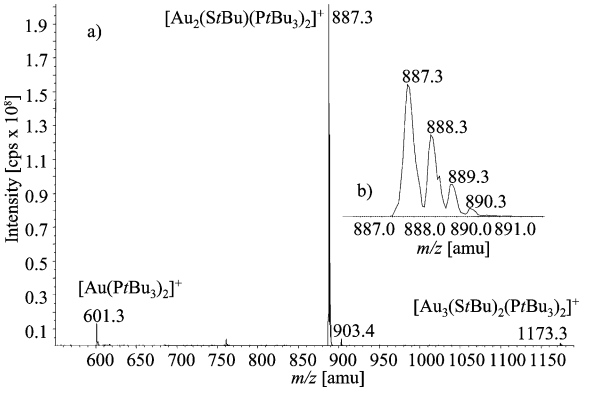

Figure 4. a) MS (ESI+) of **2c**; b) enlargement of the isotopic cluster at *m*/*z* = 887.3.

Similar conclusions can be drawn for **2d** from the analysis of its mass spectrum (Figure 5).

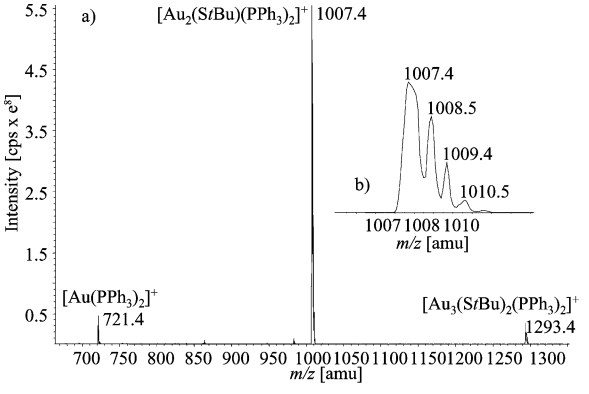

Figure 5. a) MS (ESI+) of **2d**; b) enlargement of the isotopic cluster at *m*/*z* = 1007.4.

Finally, complexes **2e**,**f** containing diphosphanes are present in solution as tetranuclear dications, as was predictable because the diphosphane holds the two dinuclear units firmly together. In the particular case of **2f**, the isotopic cluster is poorly resolved (Figure 6b) and the MS–MS spectrum of the ion at *m*/*z* = 881 shows a small peak at *m*/*z* = 1167 (Figure 6c). Because a species with more gold atoms than the precursor ion is unlikely to form on fragmentation, the presence of a fragment ion at greater *m*/*z* values confirms the tetranuclear nature of **2f**.

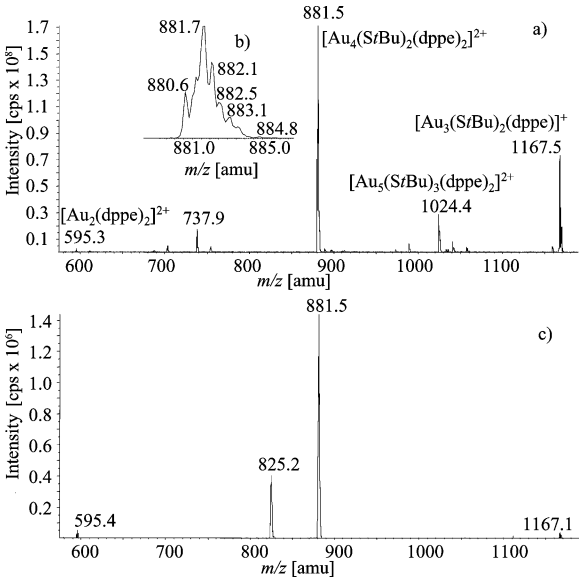

Figure 6. a) MS (ESI+) of **2f**; b) enlargement of the isotopic cluster at *m*/*z* = 881.7; c) MS–MS spectrum of the ion at *m*/*z* = 881.

From these data it is clear that the ability of **2a**–**2d** to maintain totally or partially the aurophilic interactions in solution seems to depend largely on the steric hindrance of the phosphane (then on its cone angle, which is in the order $PMe_3 < PEt_3 < PPh_3 < PtBu_3$).[10] In the case of **2e** and **2f** it is the chelating phosphane, in addition to the thiolato ligand, that binds together the four gold atoms, independently of the survival of the aurophilic interactions.

## NMR Spectroscopy

The average diffusion coefficients can be related to hydrodynamic radii $r_H$ by means of the Stokes–Einstein equation [Equation (1)].

$$D = \frac{kT}{c\pi\eta r_H} \quad (1)$$

where $k$ is the Boltzmann constant, $T$ is the absolute temperature, $\eta$ the viscosity and $c$ is a numerical factor, which usually approximates to 6 for large-size molecules.

A more accurate estimation of hydrodynamic radius $r'_H$ can be obtained[11] by Equation (2), where the $c$ factor is expressed as a function of the solvent-to-solute ratio of ra-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

dii on the basis of the model proposed by Wirtz and coworkers[12] and where $r_{solv}$ is the van der Waals radius of the solvent.

$$D = \frac{kT\left[1+0.695\left(\frac{r_{solv}}{r_H'}\right)^{2.234}\right]}{6\pi\eta r_H'} \quad (2)$$

Valentini et al.[13] used DOSY measurements to determine the diffusion coefficients of some iron and palladium compounds, whose structures in the solid state were known. They obtained the hydrodynamic radii by using the Stokes–Einstein equation and compared these results to the radii of greatest steric hindrance obtained from crystallographic parameters, $r_R$ (rotating the molecule around its geometric centre), and they found very good consistency. The technique was also exploited for the characterization of intermediates in organometallic reactions involving copper,[14] ruthenium,[15] platinum[8b] and zirconium[16] complexes. Finally, some papers report the use of this methodology to study the aggregation state in solution of organolithium[17] and ruthenium complexes.[8c,11]

Several correction factors[17b,18] for the equation, both semiempirical and theoretical have been proposed, by taking into account the dimensions and the nonspherical form of the particle, concentration and so on, but they have been used only rarely as an internal standard is preferred. Some authors[8,19] suggested the use of tetramethylsilane (TMS) as an internal standard to avoid the problems derived from the change in the viscosity due to the variation of the concentration after the addition of the solute to be analyzed and from the temperature.

The spectra were generally performed in deuterated dichloromethane, but in some cases also in methanol and acetone in order to study the influence of the solvent. As the internal standard for viscosity we adopted TMS and all diffusion coefficients were corrected with respect to it.

To test the reliability of the method, our preliminary study was directed towards thiolato phosphanyl compounds **1a**–**f**, as there is no evidence of aurophilic interactions in the solid state and presumably all the more so in solution (Table 1).

Table 1. $D$ ($\times 10^{10}$ m$^2$s$^{-1}$) and $r$ [Å] values for **1a**–**f** in $CD_2Cl_2$ at 298 K.

| | $D$ | $r_H$[a] | $r'_H$[b] | $r$[c] | $r$[d] |
|---|---|---|---|---|---|
| [Au(S*t*Bu)(PMe$_3$)] (**1a**) | 14.6 | 3.4 | 4.2 | 4.8 | 4.8 |
| [Au(S*t*Bu)(PEt$_3$)] (**1b**) | 12.6 | 4.0 | 4.7 | 5.4 | 5.1 |
| [Au(S*t*Bu)(P*t*Bu$_3$)] (**1c**) | 12.2 | 4.1 | 4.8 | 5.5 | 5.2 |
| [Au(S*t*Bu)(PPh$_3$)] (**1d**) | 10.4 | 4.9 | 5.4 | 6.1 | 6.2 |
| [Au$_2$(S*t*Bu)$_2$(dppm)] (**1e**) | 7.3 | 7.0 | 7.4 | – | 6.8 |
| [Au$_2$(S*t*Bu)$_2$(dppe)] (**1f**) | 7.2 | 7.0 | 7.4 | 7.4[e] | – |

[a] Calculated by using Equation (1), $c$ = 6, $T$ = 298 K, $\eta$ ($CD_2Cl_2$, 298 K) = $0.433 \times 10^{-3}$ kg m$^{-1}$ s$^{-1}$. [b] Calculated by using Equation (2). [c] Calculated from X-ray structure data. [d] Calculated from the minimized gas-phase structure (PM3/AM1). [e] See ref.[3]

The values of the hydrodynamic radii, calculated by employing Equation (1) with $c$ = 6, were all lower with respect to those obtained from X-ray or PM3 calculations. In the case of **1f**, which is known to be stable in solution as dissociative processes are unlikely, excellent agreement was obtained by the introduction of the Wirtz correction [Equation (2), Table 1), that is, by considering the solvent-to-solute ratio of the radii. However, the corrected hydrodynamic radii of neutral monophosphane derivatives **1a**–**d** were also slightly lower, which suggests a dissociative equilibrium. Actually, like traditional NMR measurements, DOSY techniques, in the presence of rapid exchange, show only one peak resulting from the weighted average of the signals of each species involved. Because it is well known that gold(I) compounds are often involved in rapid phosphane exchange reactions,[20] it is probable that this is the reason for the observed discrepancy between the observed and calculated radii.

We then proceeded with the NMR investigation of the series of cationic clusters **2a**–**f**. X-ray structures in the solid state are known only for [Au$_4$(S*t*Bu)$_2$(dppe)$_2$][BF$_4$]$_2$[3] (which we assume remains tetranuclear in solution) and for [Au$_4$(S*t*Bu)$_2$(PPh$_3$)$_4$][BF$_4$]$_2$;[10] for the other complexes we used data from published structures of similar model compounds or alternatively we performed PM3 calculations using the ArgusLab program.[21] As the only limitation we assumed that the S–Au–P angle had to be as close as possible to 180°. Analysis of the models of **2a**–**d** shows that the radii of greatest steric hindrance of the di- and tetranuclear species do not differ too much (ca 1 or 2 Å), as the only difference in size between the two species is in the third dimension with the assumption that the other two remain roughly constant. In spite of that, the NMR spectroscopic results shown in Table 2 are fairly consistent and point to the same conclusions reached by MS (ESI) spectrometry: the corrected hydrodynamic radius of **2a** is consistent with a tetranuclear species, whereas for **2b** it is intermediate between that of the dinuclear and the tetranuclear species, which indicates that both structures are present in solution (probably involved in rapid equilibrium).

For dppm and dppe derivatives **2e**,**f**, as expected, the radii are nicely consistent with those predicted for the tetranuclear species. Complexes **2c**,**d** gave, in contrast, even smaller $r'_H$ values than those predicted for the dinuclear species from the X-ray structure data, so they probably undergo some dissociation of the phosphane (as is likely from the literature concerning phosphane gold(I) phosphanyl derivatives and from basicity considerations in particular) or even further disruption of the remaining Au–Au interactions.

Finally, to acquire information on the influence of the solvent on the equilibrium involving di- and tetranuclear species, we made some measurements in deuterated methanol and acetone for comparison with the results obtained in dichloromethane. We chose to study triethylphosphane derivative **2b**, which, as reported above, was found to exist as a mixture of the di- and tetranuclear species, and dppe complex **2f** for comparison (Table 3).

The results for complex **2b** in acetone are fairly consistent with a dinuclear monocation formulation, which most probably means that the equilibrium observed in dichloro-

[a] Calculated by using Equation (1), $c = 6$, $T = 298$ K, $\eta_{MeOH}$ (298 K) = $0.544 \times 10^{-3}$ kg m$^{-1}$ s$^{-1}$, $\eta_{acetone}$ (298 K) = $0.306 \times 10^{-3}$ kg m$^{-1}$ s$^{-1}$. [b] Calculated by using Equation (2). [c] Calculated from the minimized gas-phase structure (PM3). [d] From X-ray data.[21]

methane is completely shifted towards the rupture of the unsupported aurophilic bonds. In methanol, **2b** shows a hydrodynamic radius that is even lower with respect to that expected for a dinuclear species; thus, some other dissociative process favoured by the polar protic solvent can be invoked. Actually, methanol seems to promote other dissociative processes even in the case of complex **2f**, which, however, maintains its tetranuclear structure in acetone as in dichloromethane.

## Conclusions

Table 4 shows our conclusions on the aggregation state of the cationic gold complexes $[Au_2(StBu)(L_2)][BF_4]$ (**2a**–**2f**) on the basis of MS and NMR experiments.

Table 4. Evaluation of the degree of aggregation of **2a**–**f** in solution by MS (ESI) and DOSY techniques.

| Complex | MS (MeOH) | DOSY ($CD_2Cl_2$) | Phosphane cone angle [°] |
|---|---|---|---|
| **2a** | tetranuclear | tetranuclear | 118 |
| **2b** | dinuclear | di- and tetranuclear | 132 |
| **2c** | dinuclear | dinuclear | 182 |
| **2d** | dinuclear | dinuclear | 145 |
| **2e** | tetranuclear | tetranuclear | – |
| **2f** | tetranuclear | tetranuclear | – |

In spite of the fact that DOSY spectroscopy and MS (ESI) are performed under rather different conditions (concentration, solvent, etc.), the results are on the whole highly consistent. The main conclusion is that some of the complexes of **2** exist in a tetranuclear form even in dilute solutions, which shows that aurophilic interactions, although not as strong as covalent bonds, are able to maintain the solid state architecture even in solution. Another conclusion seems to be that the survival in solution of the aurophilic interactions depends upon the steric hindrance of the phosphane, because the greater the cone angle, the greater the repulsion between the two monocharged unities connected by aurophilic interactions, and, as a consequence, the dinuclear is preferred to the tetranuclear structure. Moreover, apart from diphosphane derivatives **2e**,**f**, the aurophilic interactions are maintained (at least partially) only when relatively small ligands (trimethyl- and triethylphosphane) are present. Obviously the solvent plays an important role: the polarity and the affinity for gold may determine the aggregation state, as shown by triethylphosphane derivative **2b**, which completely loses its tetranuclear structure in a polar solvent like acetone and methanol, whereas it maintains the dimeric structure in part in the less-polar solvent dichloromethane.

Finally, this work, in addition to the existing literature, shows that NMR and MS techniques may be very useful in the assessment of the degree of aggregation in solution of coordination systems, and they can provide better understanding of the reactivity of species that may exist in a supramolecular aggregation.

## Experimental Section

**Chemicals:** All manipulations and reactions were carried out under an atmosphere of nitrogen or argon by using standard techniques. All solvents were used without any further purification. $[Au(SCMe_3)]_n$ was prepared according to the literature.[22]

**Physical Measurements:** $^1$H and $^{31}$P NMR spectra were recorded with a Varian Gemini 200 instrument working at 200 MHz. DOSY experiments were performed with a Varian INOVA600 spectrometer operating at 600 MHz for $^1$H by using a 5 mm broadband inverse probe with $z$ axis gradient; and the sample temperature was maintained at 25 °C. They were carried out by using a stimulated echo sequence with self-compensating gradient schemes, a spectral width of 8000 Hz and 64 K data points. Typically, a value of 100 ms was used for $\Delta$, 1.0 ms for $\delta$ and g was varied in 30 steps (16 transients each) to obtain an approximately 90–95% decrease in the resonance intensity at the largest gradient amplitudes. The base-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

lines of all arrayed spectra were corrected prior to processing the data. After data acquisition, each FID was apodized with 1.0 Hz line broadening and Fourier transformed. The data were processed with the DOSY macro (involving the determination of the resonance heights of all the signals above a preestablished threshold and the fitting of the decay curve for each resonance to a Gaussian function) to obtain pseudo-two-dimensional spectra with NMR chemical shifts along one axis and calculated diffusion coefficients along the other. Centesimal analysis were carried out in the microanalysis laboratory of Dipartimento di Scienze Farmaceutiche dell'Università di Pisa. The mass spectra were obtained with an Applied Biosystems-MDS Sciex API 4000 triple quadrupole mass spectrometer (Concord, ON, Canada), equipped with Turbo-V Ion-Spray (TIS) source. The operative parameters are as follows: ion-spray voltage (IS), 5.0 kV; gas source 1 (GS1), 25; gas source 2 (GS2), 25; turbo temperature (TEM), 0 °C; entrance potential (EP), 10 V; declustering potential (*DP*), 20 V; scan range, 300–1500 *m*/*z*. MS–MS product ions were produced by collision-induced dissociation (CID) of selected precursor ions in the LINAC collision cell (Q2) and mass-analyzed in the second mass filter (Q3). Additional experimental conditions for MS–MS product ions spectra included: collision (CAD) gas, nitrogen; CAD gas pressure, 4 m Pa; collision energy (CE), ramp from 5 to 130 eV (step = 2); collision cell exit potential (CXP), 15 V. Each sample for MS (ESI) was prepared diluting 1:100 with methanol a 5 mg mL$^{-1}$ dichloromethane solution of the target compound and was infused by a syringe pump Harvard Mod. 22 (Harvard Apparatus, Holliston, MA, USA). Melting points were obtained by using a Mel Temp II (Laboratory Devices, USA) equipped with a mercury thermometer as detector of the temperature.

**Reaction of [Au(S*t*Bu)]$_n$ with L (L = PMe$_3$, PEt$_3$, P*t*Bu$_3$, PPh$_3$). Formation of [Au(S*t*Bu)(L)] (1a–d):** The complexes were all prepared according to the literature method.[3] Compounds **1b**,**c** have not been described before.

**Complex 1a:** MS (ESI+): *m*/*z* (%) = 349 (45) $[Au(PMe_3)_2]^+$, 363 (15) $[Au(StBu)(PMe_3) + H]^+$, 635 (100) $[Au_4(StBu)_2(PMe_3)_4]^{2+}$, 761 (15) not assigned, 921 (29) $[Au_3(StBu)_2(PMe_3)_2]^+$, 997 (15) $[Au_3(StBu)_2(PMe_3)_3]^+$.

**Complex 1b:** Small silver flakes from pentane solution. Yield: 0.153 g (80%). M.p. 43 °C. $^1$H NMR (200 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 1.19 (dt, $^2J_{P,H}$ = 18.3 Hz, $^3J_{H,H}$ = 7.7 Hz, 6 H, $PCH_2$), 1.45 (s, 9 H, $SCMe_3$), 1.83 (dq, $^3J_{P,H}$ = 9.3 Hz, $^3J_{H,H}$ = 7.7 Hz, 9 H, $PCCH_3$) ppm. $^1$H NMR (200 MHz, $C_6D_6$, 25 °C): $\delta$ = 0.63 (dt, $^2J_{P,H}$ = 18.3 Hz, $^3J_{H,H}$ = 7.7 Hz, 9 H, $PCH_2$), 0.90 (dq, $^3J_{P,H}$ = 9.3 Hz, $^3J_{H,H}$ = 7.7 Hz, 6 H, $PCCH_3$), 1.93 (s, 9 H, $SCMe_3$) ppm. $^{31}$P NMR (200 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 38.64 (s) ppm. $^{31}$P NMR (200 MHz, $C_6D_6$, 25 °C): $\delta$ = 38.36 (s) ppm. $C_{10}H_{24}AuPS$ (404.31): calcd. C 29.71, H 5.98; found C 29.77, H 5.92.

**Complex 1c:** White microcrystals from toluene/pentane solution. Yield: 1.040 g (70%). M.p. 154 °C. $^1$H NMR (200 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 1.46 (s, 9 H, $SCMe_3$), 1.51 (d, $^3J_{P,H}$ = 13.2 Hz, 27 H, $PCMe_3$) ppm. $^1$H NMR (200 MHz, $C_6D_6$, 25 °C): $\delta$ = 1.93 (s, 9 H, $SCMe_3$), 1.07 (d, $^3J_{P,H}$ = 13.2 Hz, 27 H, $PCMe_3$) ppm. $^{31}$P NMR (200 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 92.58 (s) ppm. $^{31}$P NMR (200 MHz, $C_6D_6$, 25 °C): $\delta$ = 91.46 (s) ppm. MS (ESI+): *m*/*z* (%) = 361 (15) not assigned, 489 (62) $[Au(StBu)(PtBu_3)_4 + H]^+$, 512 (16) $[Au(StBu)(PtBu_3)_4 + Na]^+$, 548 (27) not assigned, 887 (100) $[Au_2(StBu)(PtBu_3)_2]^+$. $C_{16}H_{36}AuPS$ (488.47): calcd. C 39.34, H 7.43; found C 39.12, H 7.38.

**Reaction of [Au(S*t*Bu)]$_n$ with L$_2$ (L$_2$ = dppm, dppe). Formation of [Au$_2$(S*t*Bu)$_2$(L$_2$)] (1e,f):** Complexes **1f**,**e** were prepared according to a literature procedure described for **1f**.[3]

**Complex 1e:** Pale yellow microcrystals from toluene/pentane solution. Yield: 0.444 g (93%). $^1$H NMR (200 MHz, $CDCl_3$, 25 °C): $\delta$ = 1.52 (s, 18 H, $SCMe_3$), 2.38 (s, 2 H, $PCH_2$), 7.2–7.8 (br. m, 20 H, $PPh_2$) ppm. $^1$H NMR (200 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 1.46 (s, 18 H, $SCMe_3$), 3.62 (s, 2 H, $PCH_2$), 7.3–7.8 (br. m, 20 H, $PPh_2$) ppm. $^{31}$P NMR (200 MHz, $CDCl_3$, 25 °C): $\delta$ = 30.11 (s), 28.27 (s) ppm. $C_{33}H_{40}Au_2P_2S_2$ (956.69): calcd. C 41.43, H 4.21; found C 41.40, H 4.16.

**Complex 1f:** MS (ESI+): *m*/*z* (%) = 881 $[Au_4(StBu)_2(dppe)_2]^{++}$ (100%), 993 $[Au_2(StBu)_2(dppe) + Na]^+$ (25), 1024 $[Au_5(StBu)_3(dppe)_2]^{++}$ (58), 1033 (not assigned, 23), 1167 $[Au_3(StBu)_2(dppe)]^+$ (25).

**Reaction of [Au(S*t*Bu)(L)] (L = PMe$_3$, PEt$_3$, P*t*Bu$_3$, PPh$_3$) with [FeCp$_2$][BF$_4$]. Formation of [Au$_2$(S*t*Bu)(L$_2$)][BF$_4$] (2a–d):** All complexes were prepared according to the literature.[3]

**Complex 2a:** MS (ESI+): *m*/*z* (%) = 349 (85) $[Au(PMe_3)_2]^+$, 635 (100) $[Au_4(StBu)_2(PMe_3)_4]^{2+}$, 921 (14) $[Au_6(StBu)_4(PMe_3)_4]^{2+}$. MS–MS 635: *m*/*z* (%)= 273 (65) $[Au(PMe_3)]^+$, 349 (62) $[Au(PMe_3)_2]^+$, 579 (100) $[Au_4(SH)_2(PMe_3)_4]^{2+}$ or $[Au_2(SH)(PMe_3)_2]^+$, 635 (30) $[Au_4(StBu)_2(PMe_3)_4]^{2+}$.

**Complex 2b:** White microcrystals from dichloromethane solution. Yield: 0.157 g (71%). $^1$H NMR (200 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 1.59 (s, 18 H, $SCMe_3$), 1.23 (dt, $^2J_{P,H}$ = 19.1 Hz, $^3J_{H,H}$ = 7.7 Hz, 24 H, $PCH_2$), 1.94 (dq, $^3J_{P,H}$ = 9.9 Hz, $^3J_{H,H}$ = 7.7 Hz, 36 H, $PCCH_3$) ppm. $^1$H NMR (200 MHz, $C_6D_6$, 25 °C): $\delta$ = 1.55 (s, 18 H, $SCMe_3$), 0.88 (dt, $^2J_{P,H}$ = 19.1 Hz, $^3J_{H,H}$ = 7.7 Hz, 24 H, $PCH_2$), 1.61 (dq, $^3J_{P,H}$ = 9.9 Hz, $^3J_{H,H}$ = 7.7 Hz, 36 H, $PCCH_3$) ppm. $^{31}$P NMR (200 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 37.93 (s) ppm. $^{31}$P NMR (200 MHz, $C_6D_6$, 25 °C): $\delta$ = 38.36 (s) ppm. MS (ESI+): *m*/*z* (%) = 433 (14) $[Au(PEt_3)_2]^+$, 719 (100) $[Au_4(StBu)_2(PEt_3)_4]^{2+}$, 1005 $[Au_3(StBu)_2(PEt_3)_2]^+$. MS–MS 719: *m*/*z* (%) = 315 (100) $[Au(PEt_3)]^+$, 433 (67) $[Au(PEt_3)_2]^+$, 663 (72) $[Au_4(SH)_2(PEt_3)_4]^{2+}$ or $[Au_2(SH)(PEt_3)_2]^+$, 719 (6) $[Au_4(StBu)_2(PEt_3)_4]^{2+}$. $C_{16}H_{39}Au_2BF_4P_2S$: calcd. C 23.84, H 4.88; found C 23.65, H 4.76.

**Complex 2c:** Light grey microcrystals from dichloromethane solution. Yield: 0.810 g (88%). $^1$H NMR (200 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 1.61 (s, 18 H, $SCMe_3$), 1.54 (d, $^3J_{P,H}$ = 13.9 Hz, 108 H, P*t*Bu) ppm. $^{31}$P NMR (200 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 92.74 (s) ppm. MS (ESI+): *m*/*z* (%) = 601 (6) $[Au(PtBu_3)_2]^+$, 887 (100) $[Au_2(StBu)(PtBu_3)_2]^+$, 1173 (6) $[Au_3(StBu)_2(PtBu_3)_2]^+$. # The Structure of Potassium and Tetramethylammonium Salts of the Cyclic Organohydroborate Anion $[H_2BC_8H_{14}]^-$ with Different Solvent Ligands

**Xuenian Chen,[a] Shengming Liu,[a] Bin Du,[a] Edward A. Meyers,[a] and Sheldon G. Shore*[a]**

**Keywords:** Agostic interactions / X-ray diffraction / Organohydroborate / Potassium salts

Solvated potassium salts of the 9-BBN hydroborate anion have been prepared and their structures have been determined by single-crystal X-ray diffraction analyses. A tetrameric complex $\{LK[(\mu\text{-}H)_2BC_8H_{14}]\}_4$ is formed when L is toluene, MeTHF, toluene/THF, THF/$Et_2O$ mixtures. The basic framework consists of a distorted $K_4B_4$ cube in which potassium and boron are at alternate corners of the cube linked by bridging hydrogen atoms and α-C–H hydrogen atoms from the 9-BBN hydroborate that appear to form agostic interactions with potassium. There are two types of bridging hydrogen atoms: one is connected to three potassium atoms and one boron atom in a $\mu_4$-coordination arrangement, and the other one is connected to two potassium atoms and one boron atom in a $\mu_3$-coordination arrangement. There are four $\mu_4$-hydrogen arrangements in the structure. They are located inside of the $K_4B_4$ cube. The four $\mu_3$-hydrogen arrangements are located outside of the distorted $K_4B_4$ cube. The coordination number of potassium is 8 with the three $\mu_4$-, two $\mu_3$-bridging hydrogen atoms, two α-C–H hydrogen atoms, and one oxygen atom of the solvent, L (there is a weak $\pi\text{-}\eta^6$ interaction when the solvent is toluene). On the other hand, in the chelating solvent DME, a dimeric structure is formed in which the inner part is planar with potassium and boron located at alternate corners. The potassium is connected to four $\mu_3$-bridging hydrogen atoms, two apparent agostic α-C–H bonding hydrogen atoms, and four oxygen atoms of two DME molecules. Its coordination number is 10 including the agostic interactions. The structure of the uncoordinated $[H_2BC_8H_{14}]^-$ anion is observed in the tetramethylammonium salt.

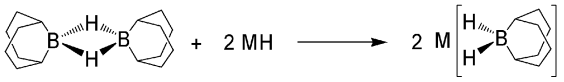
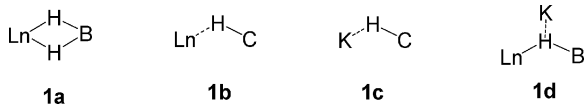
## Introduction

Alkali metal (cyclooctane-1,5-diyl) dihydroborates (9-BBN hydriborate anion) have been readily prepared through the reaction of 9-borabicyclo[3.3.1]nonane dimer (9-BBN) with alkali metal hydrides in ether solvents[1] [reaction (1)]. These organohydroborates have been employed as chelating ligands through B–H–M bridges to produce a variety of complexes with transition metals,[2] lanthanides,[3,4] and actinides.[5]



(1)

In the divalent lanthanide complexes $[K(MeTHF)_3]_2\{Ln[(\mu\text{-}H)_2BC_8H_{14}]_4\}$ (MeTHF = 2-methyltetrahydrofuran, Ln = Eu, Yb),[3] four types of interaction between hydrogen and the metal atoms are reported (Scheme 1). The interactions **1a** and **1b** represent the commonly observed metal–hydrogen–boron bridge bond and metal-agostic hydrogen interactions observed in transition and lanthanide metal complexes of the 9-BBN hydroborate ion. The interactions **1c** and **1d** are observed in the complexes $[K(MeTHF)_3]_2\{Ln[(\mu\text{-}H)_2BC_8H_{14}]_4\}$.[3]



Scheme 1.

These observations provide the impetus to determine if interactions such as **1a**–**c**, and analogs of **1d** exist in the potassium salt of the anion $[(\mu\text{-}H)_2BC_8H_{14}]^-$. Thus investigation of the structure of the potassium salt of the 9-BBN hydroborate anion $[H_2BC_8H_{14}]^-$ was carried out. It was found that the structure of the potassium salt is a tetramer when crystallized as a toluene solvate. To compare the effect of solvate on the molecular character of $K[(\mu\text{-}H)_2BC_8H_{14}]$, crystals were also grown from MeTHF, DME, and mixed solvents. The structure of $[NMe_4][H_2BC_8H_{14}]$ was also determined since that of the uncoordinated 9-BBN hydroborate is apparently previously unreported.

## Results and Discussion

### 1. Preparation

The solvate-free potassium salt of 9-BBN hydroborate was prepared by the literature method.[1] Samples were dis-

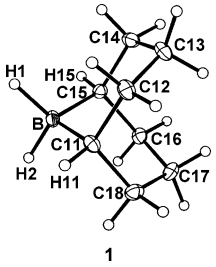
solved in the solvents toluene, 2-methyltetrahydrofuran (MeTHF), DME, a 1:1 mixture of toluene and THF, and a 1:1 mixture of THF and ether to form the corresponding solutions of the potassium salt. From these solutions, crystals suitable for X-ray diffraction analysis were obtained by slowly evaporating the solvent. The tetramethylammonium salt of 9-BBN hydroborate was prepared by a metathesis reaction between $K[H_2BC_8H_{14}]$ and $[NMe_4]Cl$ in THF and characterized by proton NMR, elemental analysis and single-crystal X-ray diffraction analyses. Crystal data are given in Table 1.

## 2. Structures

### *2.1 Structure of [NMe$_4$][H$_2$BC$_8$H$_{14}$] (1)*

The reported lithium salts of 9-BBN hydroborates, $[(OEt_2)Li(H_2BC_8H_{14})]_2$, $[(THF)_2Li(H_2BC_8H_{14})]_2$, and $[(THF)_{0.5}(TMEDA)_{0.5}Li(H_2BC_8H_{14})]_2$ [DMEDA = $(CH_3)_2N(CH_2)_2N(CH_3)_2$] have been shown to be the dimers.[6] Interaction between alkali metal and the bridging hydrogen atoms and α-C–H hydrogen atoms occurs in these complexes. Sodium 9-BBN hydroborates, to the best of our knowledge, are unreported. Potassium 9-BBN hydroborates were reported earlier,[1] but without X-ray structures. In addtition to our earlier reported studies of the potassium 9-BBN hydroborate complexes of Yb and Eu,[3,4] we have examined and report here the structures of several potassium 9-BBN hydroborate solvates and that of the solvent free anion.

In order to obtain a structure of a simple 9-BBN anion not coordinated to a cation, the tetramethylammonium salt of 9-BBN hydroborate was prepared. The structure of the $[NMe_4][H_2BC_8H_{14}]$ (**1**) is relatively simple, that of an ionic complex with separated $[NMe_4]^+$ cation and $[H_2BC_8H_{14}]^-$ anion. The structure of the anion is shown in Figure 1. This allows us to observe changes in the structure of the anion when it is coordinated to potassium in compounds **2**, **3** and **4** and a detailed discussion follows later. In the cation, average values are C–N 1.496(2) Å, C–H 0.97(2) Å, C–N–C 109.5(6)°, N–C–H 107.3(7)° and H–C–H 111.5(15)°.



1

Figure 1. The structure of **1**, showing 25% probability thermal ellipsoids. Coordinates and isotropic temperature factors of all hydrogen atoms were allowed to vary and are drawn with arbitrary thermal ellipsoids.

### *2.2 Structure of {(Tol) K[(μ-H)$_2$BC$_8$H$_{14}$]}$_4$ (2)*

The gross features of the structure of **2** (Figure 2, a) consist of a foundation that is a distorted $K_4B_4$ cube, with potassium and boron at alternate corners (Figure 2, b). The distances of K–B10, K–B10A, and K–B10B, three edges of the distorted cube, are 3.083(2), 3.749(2), and 3.033(2) Å. Angles B10–K–B10A, B10–K–B10B, and B10A–K–B10B are 92.7(1)°, 106.0(1)°, and 91.5(1)°, while the angles K–B10–K0A, K–B10–K0C, and K0A–B10–K0C are 85.7(1)°, 86.6(1)°, and 75.6(1)°. There are two types of bridging hydrogen atoms: four, four coordinate $\mu_4$-H that reside in the cube and four three coordinate $\mu_3$-H that are situated outside the cube (Figure 2, c). The unit may also be described as a cluster with its centroid at coordinates (0.5, 0.75, 0.625) and a fourfold axis of rotary-inversion along the crystal c-direction.

Potassium is also $\eta^6$-π coordinated to toluene and is involved in agostic interactions with two α-CH hydrogen atoms of the 9-BBN hydroborate ligands. The four $\mu_3$ external bridging hydrogen atoms are located over four of the faces of the $K_4B_4$ cube and are close to being coplanar. In contrast, the four $\mu_4$ bridging hydrogen atoms inside the cube are at the corners of a tetrahedron. This tetrahedron is inverted with and rotated approximately 60° with respect to the potassium tetrahedron, but maintains the same orientation as the boron tetrahedron (Figure 2, d). The potassium is bonded to three $\mu_4$-H bridging hydrogen atoms and two $\mu_3$-H bridging hydrogen atoms. The K–H distance with four-coordinate hydrogen atoms are 2.610(13), 2.750(13), and 2.917(13) Å, compared to those with three coordinate hydrogen atoms, 2.653(13) and 2.762(13) Å.

It is of interest that the cubic arrangement is also observed in the tetrameric sodium hydroborate complexes $[(NaBMe_3H)_4OEt_2]$[7] and $NaBH_4$·TMTA (TMTA = trimethyltriazacyclononane).[8] But it is worth noting that in $NaBH_4$·TMTA, the $BH_4$ group supplies only one hydrogen atom for bridging to three Na centers, while the 9-BBN hydroborate ligand in complex **2** provides two bridging hydrogen atoms one of which is coordinated to three K atoms as $\mu_4$-bridging hydrogen atoms and the other is coordinated

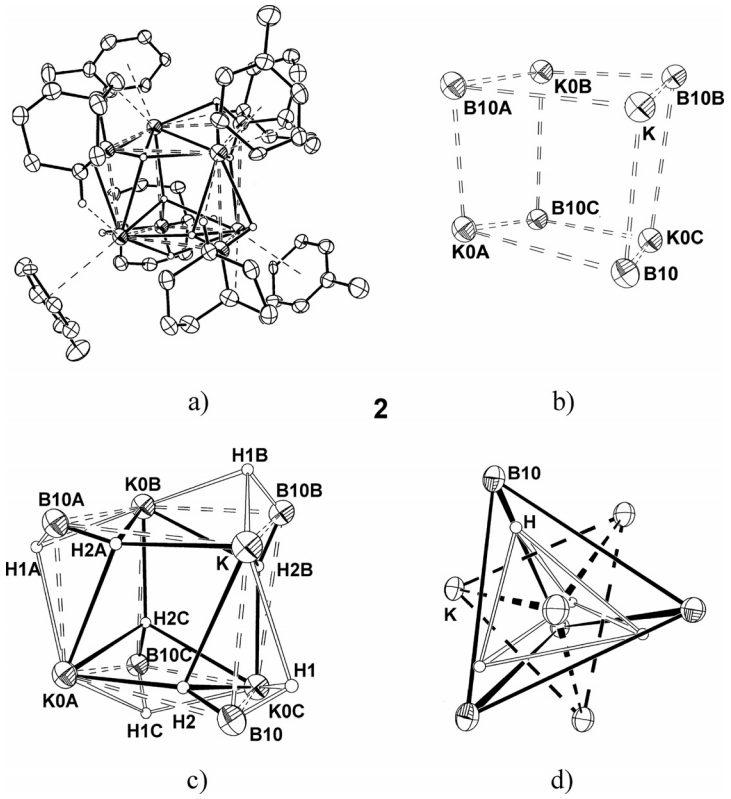

Figure 2. a) The structure of **2**, showing 25% probability thermal ellipsoids. Bridging hydrogen atoms and α-hydrogen atoms are drawn with arbitrary thermal ellipsoids. All other hydrogen atoms omitted for clarity. b) The distorted $K_4B_4$ cube of the structure of **2**. Distances [Å]: K–B10 3.083(2); K–B10A 3.749(2); K–B10B, 3.033(2); angles [°]: B10–K–B10A 92.7(1), B10–K–B10B 106.0(1), B10A–K–B10B 91.5(1), K–B10–K0A 85.7(1), K–B10–K0C 86.6(1), K0A–B10–K0C 75.6(1). The twofold rotation axis along the *c*-direction relates K to K0A, K0B to K0C, B10 to B10A, B10B to B10C. The K atoms are calculated to be 2.67 Å from the centroid and the B atoms 3.01 Å. c) The interactions between the potassium and the $\mu_4$- and $\mu_3$-coordination bridging hydrogen atoms in the structure of **2**. Distances [Å]: K–H1 2.653(13), K–H1B 2.762(13), K–H2 2.917(13), K–H2A 2.610(13), K–H2B 2.750(13) and B10–H1 1.259(14), B10–H2 1.234(14). d) The relationship among the three tetrahedrons. Four $\mu_4$-hydrogen atoms at distances [Å]: H2–H2A 2.99(2), H2–H2B 3.39(2), H2–H2C 3.39(2); angles [°]: H2–H2B–H2A 63.8(5), H2–H2C–H2A 63.8(5), H2–H2C–H2B 52.5(4); four potassium atoms at distances [Å]: K–K0A 4.673(2), K–K0B 4.196(2), K–K0C 4.196(2); angles [°]: K–K0C–K0A 56.2(1), K–K0B–K0A 56.2(1), K–K0C–K0B 67.7(1); four boron atoms at distances [Å]: B10B–B10A 4.964(2), B10–B10B 4.886(2), B10–B10C 4.886(2); angles [°]: B10–B10B–B10A 59.5(1), B10–B10C–B10A 59.5(1), B10–B10C–B10B 61.1(1).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

to two K atoms as $\mu_3$-bridging hydrogen atoms. The coordination geometries of the $\mu_4$-bridging hydrogen atoms in complex **2** are very similar to those in the $Na_4H_4$ unit in the complexes $(NaBMe_3H)_4OEt_2$ and tetrameric $NaBH_4$·TMTA.[7,8]

In complex **2**, the potassium also interacts with two α-C–H hydrogen atoms by apparent agostic interaction (Figure 2, a). These occur between the K atom and H11 and H15 with distances of K–H11, 2.716(16) and K–H15, 2.769(16) Å, which are comparable to the distances of potassium with bridging hydrogen atoms, K–H1 [2.653(14), 2.762(14) Å] and K–H2 [2.917(14), 2.610(14) Å, 2.750(14) Å].

In the molecular structure of complex **2** (Figure 2, a), the toluene molecule is disordered with fractional occupancies of 0.581(5) for part (A) and 0.419(5) for part (B). They interact in $\eta^6$-π coordination with potassium with the K–C distances ranging from 3.267(8) to 3.407(12) Å. Though long known experimentally and much studied theoretically, alkali metal-π (arene) interactions have recently taken on a new significance with the suggestion that intramolecular cationic interactions with (electron-rich) aromatic centers can influence protein structures.[9] Such interaction can best be described as an induced dipole interaction[10] with K–C distances for the $\eta^6$-bound toluene molecules in the range 3.267(8)–3.407(12) Å.[11,12] These distances are comparable to those found in the group of K-$\eta^6$-toluene in corresponding complexes. The interactions between K and $\eta^6$-toluene as well as with two α-C–H hydrogen atoms also contribute to the stabilization of the tetrameric species of **2** in addition to the potassium to BH contacts.

### *2.3 Structure of [(THF)$_2$(Tol)$_2$K$_4$]{H$_2$BC$_8$H$_{14}$}$_4$ (3)*

The structure of **3** was obtained from a single crystal grown in a mixed solvent of THF and toluene in approximately 1:1 ratio (Figure 3, a). It is a tetrameric structure with two THF and two toluene ligands coordinated to four potassium atoms. [One of the 9-BBN ligands is disordered with occupancies for part B1 = 0.743(3) and 0.247(3) for part B3. Only the B1 anion is drawn in the figures.] The arrangement of 9-BBN hydroborate anions coordinated to potassium is different than that in structure **2**. The $K_4B_4$ cube is much more distorted. Though the $\mu_3$- and $\mu_4$-types of bridging hydrogen atoms exist in the structure of **3**, the geometrical arrangement differs from that in structure **2**. Four $\mu_4$-bridging hydrogen atoms are still located inside of the $K_4B_4$ distorted cube, which is similar to that in structure **2**. However, four $\mu_3$-bridging hydrogen atoms are associated with only two faces (Figure 3, b).

This arrangement differs from that of **2**, in which four $\mu_3$-bridging hydrogen atoms are located at four faces (Figure 2, c). Thus the twelve K–B edges of the distorted $K_4B_4$ cube are divided into two types, four with an average length 3.702(4) Å and eight shorter ones with an average length of 3.020(4) Å. The centroid of this structure is at (0.5, 0.40699, 0.25) and it possesses a twofold axis parallel to the *b*-axis of the crystal (Figure 3, b) in a manner similar to that of structure **2**. The distances of potassium and bridging hydrogen atoms fall in the normal range with the longest 2.82(2) Å and the shortest 2.60(3) Å. In addition, potassium also appears to interact with two α-C–H hydrogen atoms by agostic interaction to complete its coordination sphere. The potassium α-C–H hydrogen distances: K1–H15 2.80(2), and K2–H11 2.75(2) Å are comparable to those in structure **2**.

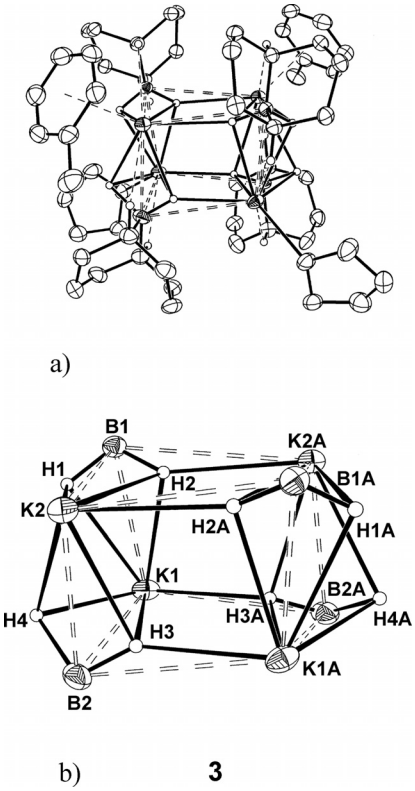

Figure 3. a) The structure of **3**, showing 25% probability thermal ellipsoids. Bridging hydrogen atoms and α-hydrogen atoms are drawn with arbitrary thermal ellipsoids. All other hydrogen atoms omitted for clarity. b) The interactions between the potassium and $\mu_4$- and $\mu_3$-bridging hydrogen atoms in the structure of **3**. Distances [Å]: K1–B2A 3.636(4), K2–B1A 3.768(5), K1–B1 2.987(2), K1–B2 3.038(4), K2–B1 3.026(2), K2–B2 3.028(4), K1–H1 2.63(2), K1–H2 2.71(4), K1–H3 2.71(2), K1–H4 2.75(3), K2–H1 2.67(2), K2–H2 2.82(2), K2–H3 2.71(2), K2–H4 2.60(3); angles [°]: B1–K1–B2 97.29(8), B1–K1–B2A 103.3(1), B2–K1–B2A 96.1(1), B1–K2–B2 96.66(9), B1–K2–B1A 90.9(1), B2–K2–B1A 99.5(1), K1–B1–K2 82.63(6), K1–B1–K2A 77.7(1), K2–B1–K2A 87.5(1), K1–B2–K2 81.76(9), K1–B2–K1A 81.8(1), K2–B2–K1A 79.4(1).

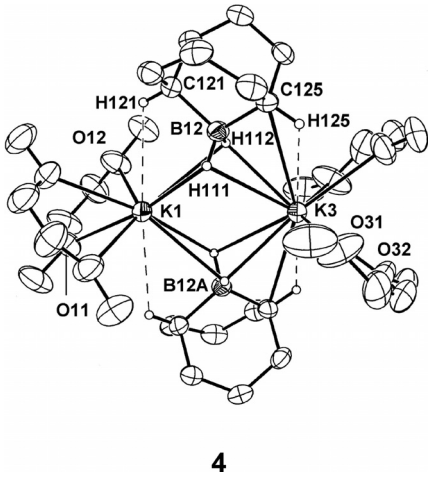
### *2.4 Structure of [(DME) K(H$_2$BC$_8$H$_{14}$)]$_2$ (4)*

The molecular structure of **4** is a dimer. In the asymmetric unit there are two half-molecular fragments that produce two similar molecules through symmetry operations. In one molecule a twofold axis passes through K1 and K3 and is perpendicular to B12–B12A. In the other a twofold axis passes through B1 and B2 and is perpendicular to K2–K2A. One molecule is displayed in Figure 4 in which K1, K3, B12, and B12A are shown. Distances B12–K1 and B12–K3 are 3.156(5) and 3.125(5) Å; angles K1–B12–K3, B12–K1–B12A, and B12–K3–B12A are 82.73(9), 96.6(2), and 97.9(2)°. The K1–K3 distance, 4.151(2) Å, is compar-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

able to those in structure **2**. Each potassium atom is bound to four oxygen atoms from the DME ligands, four bridging hydrogen atoms, and two α-C–H hydrogen atoms by agostic interaction. All bridging hydrogen atoms are bound to one boron atom and two potassium atoms as $\mu_3$-hydrogen atoms. The K1–H121 distance of 2.98(4) Å is comparable to 2.68(3) Å of the K1–H111, 2.91(4) Å of K1–H112, here the hydrogen atoms come from the K–H–B bridges. The K1–O11 and K1–O12 distances are 2.765(4) and 2.808(3) Å which are comparable to ordinary K–O bond lengths.[3] Thus the coordination number of K appears to be 10. Corresponding values for the second molecule present in the structure are given in the electronic supporting information.



**4**

Figure 4. The structure of **4**, showing 25% probability thermal ellipsoids. Bridging hydrogen and α-hydrogen atoms are drawn with arbitrary thermal ellipsoids. All other hydrogen atoms omitted for clarity. The interaction between the potassium and the four oxygen atoms from the two DME and six hydrogen atoms including the four $\mu_3$-bridging hydrogen atoms, and the two α-C–H hydrogen atoms by agostic interaction. Distances [Å]: K1–O11 2.808(3), K1–O12 2.765(4), K1–H111 2.68(3), K1–H112 2.91(4), K1–H121 2.98(4).

Table 2 compares bond parameters of **1**, **2**, **3**, **4** and the 9-BBN dimer $(C_8H_{14}B)(\mu\text{-}H)_2(BC_8H_{14})$.[13] For the compounds bond parameters are not noticeably different with the exception of the B–H distance in **4** which is still within $2\sigma$ of the corresponding bond length in the other 9-BBN hydroborate ligands. That the $[H_2BC_8H_{14}]^-$ anion readily functions as a ligand in forming bridge bonds with potassium in the dimeric and tertrameric molecules can be related to the fact that these bond parameters are virtually unchanged in the formation of the dimeric and tetrameric complexes (see electronic supporting information for details). This also appears to be true for the dimeric 9-BBN hydroborate complexes of lithium.[6]

That with the solvent DME a dimer is formed rather than a tetramer is related to the fact that the DME is bidentate with its two oxygen atoms coordinating to potassium, thereby occupying an additional coordination site than the monodentate ether ligands thus blocking possible further association through a K–H–B bridge. Compared to the 9-BBN dimer, the obvious difference is that the angle of H–B–H, 87(2)°, is about 20° smaller than those in **1**, **2**, **3** and **4**.[14] This smaller HBH angle in the 9-BBN dimer and other diboranes probably relates to the significantly smaller size of boron compared to the alkali metals.[15]

Table 2. The comparison of bond parameters that involve the boron atom in complexes **1**, **2**, **3**, **4** and 9-BBN dimer {all data are average value and the standard deviations of the average values are calculated either by $[\Sigma(l_i - l)^2/n(n-1)]^{1/2}$ or $1/n(\Sigma\sigma_i^2)^{1/2}$, the larger value being reported}.

| | Distances [Å] | | Angles [°] | | |
|---|---|---|---|---|---|
| | B–H | B–C | H–B–H | H–B–C | C–B–C |
| **1** (ion pair) | 1.195 (10) | 1.626(3) | 107.5(9) | 111.2(4) | 104.98(8) |
| **2** (tetramer) | 1.247 (12) | 1.627(3) | 108.7(9) | 110.8(7) | 104.89(13) |
| **3** (tetramer) | 1.16(2) | 1.628(19) | 106.6(22) | 111.9(21) | 103.9(9) |
| **4** (dimer) | 1.08(8) | 1.629(9) | 106(2) | 112(1) | 103.9(5) |
| 9-BBN dimer | 1.25(2) | 1.567(2) | 87(2) | | 111.8(3) |

### *2.5 Structures of [(MeTHF) K($H_2BC_8H_{14}$)]$_4$ (5), [($OEt_2$) K($H_2BC_8H_{14}$)]$_4$ (6a) and [(THF)$_2$($OEt_2$)$_2$$K_4$]-{$H_2BC_8H_{14}$}$_4$ (6b)*

Poor quality crystals of **5** were grown from 2-methyltetrahydrofuran (MeTHF) and of **6** from mixtures of THF and diethyl ether (see chapter X-ray Structure Determination and the electronic supporting information for details). The structure of molecule **5** is similar to that of **2**. The K–K distances in **5** range from 4.050(6) to 4.506(6) Å. They are comparable to those in structure **2**. The formation of the tetramer is believed to be mainly dependent on the interaction between potassium and bridging hydrogen atoms. When the solvent is a monodentate ligand or a π donor the tetrameric structure is formed. The potassium is bound to one oxygen atom from 2-methyltetrahydrofuran (MeTHF) and seven hydrogen atoms including three $\mu_4$-hydrogen atoms, two $\mu_3$-hydrogen atoms, and two α-C–H hydrogen atoms by agostic interactions. The K–H distances range from 2.64(6) to 2.86(7) Å. They are not significantly different whether the hydrogen is from $\mu_4$-hydrogen atoms or $\mu_3$-hydrogen atoms, even from α-C–H hydrogen atoms by agostic interaction.

There are two independent molecules **6a** and **6b** in the unit cell for the structure of a single crystal obtained from the mixed solvent of ether and THF. The structure of **6a** contains four ether molecules, while the structure of **6b** contains two ether molecules and two THF molecules coordinated to potassium atoms, respectively. Both structures are tetramers and the inner part is the distorted $K_4B_4$ cube and the structural descriptions are similar to those of **2** and **3**.

## Summary

The solid-state structure of an alkali metal 9-BBN hydroborate is dependent on the alkali metal size and other coordinating ligands. The 9-BBN hydroborate salts of lithium are dimeric structures with ether or THF ligands. The coordination number of lithium is 5 or 6 with bridging hydrogen atoms, α-C–H hydrogen atoms in agostic interactions, and oxygen atoms of ether or THF in the structure of those

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

complexes.[6] However, the 9-BBN hydroborate salts of potassium, form tetrameric structures in the non-coordinating solvent toluene, the single dentate coordinating solvents MeTHF, THF, ether, and/or their 1:1 mixtures. The coordination number is 8 with three $\mu_4$-, two $\mu_3$-bridging hydrogen atoms, two α-C–H hydrogen atoms and one oxygen atom of solvent (or the weak $\eta^6$ interaction with the π system of toluene). The chelating ligand DME prevents formation of the tetramer of 9-BBN hydroborate salt instead the dimer, **4**, is formed in which the coordination number of potassium is 10 with four $\mu_3$-bridging, two α-C–H hydrogen atoms and four oxygen atoms of the DME ligand.

The striking structural feature of the tetrameric structure of the potassium salts of 9-BBN hydroborate is that the $K_4B_4$ core is a much distorted cube. Similar arrangements occur in complexes $(NaBMe_3H)_4OEt_2$[7] and $NaBH_4$·TMTA,[8] which have only one bridging hydrogen. In contrast to a very distorted $K_4B_4$ cube in the potassium salts of 9-BBN hydroborate, a much more regular $M_4O_4$ cube is a typical structure for alkali metal alkoxides $[MOR]_4$.[16] In the systems studied, interaction between B–H hydrogen atoms and α-C–H hydrogen atoms with potassium is a question of interest. Evidences for such interactions have been given by single-crystal X-ray diffraction and infrared and NMR spectroscopy.[17] The spectra we obtained were too complicated to decipher with confidence. But low temperature single-crystal X-ray diffraction, is suggestive of such an interaction.

The tetramethylammonium salt of 9-BBN hydroborate provides the structure of the anion $[H_2BC_8H_{14}]^-$.

## Experimental Section

**General Comments:** All manipulations were carried out on a standard high vacuum line or in a dry box under nitrogen. Toluene, 2-methyltetrahydrofuran, tetrahydrofuran, DME, and ether were dried with sodium/benzophenone and freshly distilled prior to use. Celite was dried by heating at 150 °C under dynamic vacuum for 5 h. Potassium hydride (Aldrich) was received as an oil slurry, washed with hexane, vacuum dried, and stored in the drybox. $C_8H_{14}B(\mu\text{-}H)_2BC_8H_{14}$, and $NMe_4Cl$ were purchased from Aldrich and used as received. Solvent-free $K[H_2BC_8H_{14}]$ was prepared by literature procedures.[1] Elemental analyses were performed by Galbraith Laboratories, Inc. of Knoxville, TN, U.S.A. NMR spectra were recorded with a Bruker AM-250 spectrometer. $^1H$ NMR spectra were obtained at 250.1 MHz, and referenced to residual solvent protons. $^{11}B$ NMR spectra were obtained at 80.3 MHz, and externally referenced to $BF_3$·$OEt_2$ in $C_6D_6$ ($\delta$ = 0.00 ppm). Infrared spectra were recorded with a Mattson–Polaris FT-IR spectrometer with 2 $cm^{-1}$ resolution.

**X-ray Structure Determination:** Single-crystal X-ray diffraction data were collected with a Nonius Kappa CCD diffraction system, which employs graphite-monochromated Mo-$K_\alpha$ radiation ($\mu$ = 0.71073 Å). A single crystal of a complex, **1** to **6**, was mounted on the tip of a glass fiber coated with Fomblin oil (a pentafluoro polyether). Unit cell parameters were obtained by indexing the peaks in the first 10 frames and refined employing the whole data set. All frames were integrated and corrected for Lorentz and polarization effects using the DENZO-SMN package (Nonius BV, 1999).[18] The empirical absorption correction was applied with the SORTAV program[19] provided by *MaXus* software.[20] The positions of the heavy atom K were revealed by the Patterson method. The structures were refined using the SHELXTL-97 (difference electron density calculations and full-matrix least-squares refinements) structure solution package.[21] Data merging was performed using the data preparation program supplied by SHELXTL-97. Other calculations was made using WinGX (version 1.70.01), which includes Platon, Parst programs.[22] After all non-hydrogen atoms were located and refined anisotropically, hydrogen atom positions were calculated assuming standard geometries. All hydrogen atoms of both the organohydroborate ring and the tetramethylammonium group in **1**, all hydrogen atoms of the organohydroborate ring in **2**, and bridge hydrogen atoms and α-hydrogen atoms of the organohydroborate ring in **3** to **6** were located on difference maps and their positional and isotropic thermal parameters were refined. This is the commonly accepted procedure for locating hydrogen atoms by X-ray diffraction and distances are probably within a 0.1 Å if the atom bound to hydrogen is not a heavy fifth or sixth row element.

In **2** the toluene molecule is disordered [fractional occupancies 0.587(6), 0.413(6)] with average ring distances <C–C> 1.39(2) and 1.38(5) Å, respectively, and for the ordered 9-BBN group <C–C> 1.535(2) Å. In **3**, one 9-BBN group is ordered, <C–C> 1.534(2) Å. A second 9-BBN group is disordered [fractional occupancies 0.745(4) and 0.255(4)] with <C–C> 1.535(5), 1.53(1) Å, respectively. All agostic contacts have been calculated only with respect to the ordered 9-BBN group. In **4** there is no apparent disorder and for the three independent 9-BBN groups present <C–C> 1.523(5), 1.523(2), and 1.520(2) Å. The crystals grown for compounds **5** and **6** were of poor quality. Crystals of **5** were merohedrally twinned and disordered while many atoms in the THF and ether ligands of **6** were split and large difference electron density residuals remained after all atoms had been located. The data for these compounds has been relegated to the supporting information.

CCDC-620329 to -620334 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Center via www.ccdc.cam.ac.uk/data_request/cif.

**Preparation of $[NMe_4][H_2BC_8H_{14}]$ (1):** $K[H_2BC_8H_{14}]$ (0.162 g, 1.0 mmol) and $NMe_4Cl$ (0.110 g, 1.0 mmol) were put into a flask in the dry box. The flask was degassed and about 10 mL of THF was condensed into the flask. The system was warmed and stirred at room temperature for 3 h to produce **1** and a KCl precipitate. Then the mixture was filtered to remove the KCl solid. THF solution was concentrated at room temperature and colorless X-ray quality crystals 0.180 g (0.91 mmol, 91.3% yield) formed. $^{11}B$ NMR (250 MHz, [$D_8$]toluene, 25 °C, $BF_3$·$OEt_2$): $\delta$ = –15.0 (t) ppm. $^1H$ NMR (250 MHz, [$D_8$]toluene, 25 °C, TMS): $\delta$ = 2.36 (s, 12 H, Me), 2.27–0.658 (m, α-, β-, γ-H of $H_2BC_8H_{14}$ unit) ppm. $^1H\{^{11}B\}$ NMR (250 MHz, [$D_8$]toluene, 25 °C, TMS): $\delta$ = 1.34 (s, $\mu$-H of $H_2BC_8H_{14}$ unit) ppm. IR (KBr): $\tilde{\nu}$ = 3108 (w), 3074 (m), 2975 (w), 2920 (sh), 2873 (vs), 2826 (s), 1960 (w), 1849 (s), 1828 (sh), 1794 (m), 1733 (w), 1699 (m), 1651 (m), 1557 (m), 1539 (m), 1425 (vs), 1401 (sh), 1341 (s), 1315 (sh, w), 1284 (m), 1261 (m), 1203 (m), 1168 (w), 1111 (m), 1067 (m), 1041 (m), 1014 (vs), 928 (m), 888 (m), 865 (w), 828 (sh), 805 (vs), 734 (m), 463 (m) $cm^{-1}$. $C_{12}H_{28}BN$ {$[N(CH_3)_4]$ $(H_2BC_8H_{14})$} (197.17): C 73.09, H 14.31, N 6.09; found C 73.18, H 14.70, N 5.84.

**Preparation of $\{(Tol)K[(\mu\text{-}H)_2BC_8H_{14}]\}_4$ (2):** Solvent-free $K[H_2BC_8H_{14}]$ (0.2 g) was dissolved in toluene to produce a $K[H_2BC_8H_{14}]$ solution. After it was filtered, the solution was con-

# Functionalised Hybrid Materials of Conducting Polymers with Individual Fibres of Cellulose

**Fern M. Kelly,*[a] James H. Johnston,[a] Thomas Borrmann,[a] and Michael J. Richardson[a]**

**Keywords:** Polypyrrole / Polyaniline / Cellulose / Fibres / Conductivity / Antimicrobial activity

Polypyrrole and polyaniline conducting polymer composites with individual fibres of cellulose have been successfully prepared and characterised. For this, individual Kraft paper pulp fibres have been fully encapsulated with polypyrrole and polyaniline by direct polymerisation of the respective monomers using ferric chloride and ammonium persulfate as the oxidants. These novel conducting polymer/cellulose fibre composite materials exhibit the inherent properties of both components. They include the electrical and chemical properties of polypyrrole and polyaniline and the strength, flexibility and available surface areas of the cellulose fibre. This allows for interesting opportunities for the development of new added-value products in the paper and packaging industries. Additionally, by utilising the redox active surface of the fibre's polymer coating, silver ions have been reduced to silver metal, thereby producing cellulose/conducting polymer/silver composites. Silver and its compounds have long been identified for their bactericidal effects and thus antimicrobial properties are imparted to the hybrid materials. This gives rise to applications requiring the inhibition of microbial growth. The chemical and physical characterisation of such products has been carried out using scanning electron microscopy (SEM), cyclic voltammetry, X-ray photoelectron spectroscopy (XPS) energy dispersive spectroscopy (EDS) and electrical conductivity measurements, and additionally the testing of their antimicrobial activity.

## 1. Introduction

Inherently conducting polymers have been widely investigated since their introduction in the 1970's due to their excellent electrical and optical properties.[1] Electrical conductivity arises from the conjugation of π electrons formed by the overlapping of carbon *p* orbitals along the polymer-chain backbone which allows for the efficient transfer of electrons along the polymer backbone.[2] High electrical conductivity can be achieved by doping the conductive polymer with an appropriate agent, which can be either electron-rich (*n*-dopant) or -poor (*p*-dopant) in comparison to the polymer.

Two of the most commonly studied conductive polymers are polypyrrole (PPy) and polyaniline (PAn). This is due to their high electrical conductivity, good environmental stability, chemical properties (oxidation/reduction) and relative ease of synthesis. However, due to their poor mechanical properties and processability industrial application has been cautious. Improvement of the properties of conducting polymers is achievable by creating hybrid materials, in which textile fibres are coated with conducting polymers. In doing so, the hybrids possess the tensile strength, flexibility and relatively high surface area associated with the fibre whilst retaining the desired chemical and electrical properties of the polymer.[3]

Previous studies have shown that individual synthetic organic polymer fibres, such as Nylon and Lycra, may be successfully coated with conducting polymers.[4–6] These materials have applications as chemical and bio-mechanical sensors. This paper conversely presents individual natural fibres of cellulose (Kraft paper pulp) that have been successfully coated by PPy and PAn, using ferric chloride or ammonium persulfate to facilitate polymerisation. As the surface morphology of nylon and other synthetic polymer fibres is much smoother and more uniform than cellulose, the surface of a conducting polymer/nylon fibre, which similarly encapsulates the fibre substrate, is also smoother than that of the PPy/cellulose and PAn/cellulose composite fibres. The chemical and physical properties of the conducting polymer coating and the bonding between the conducting polymer coating and cellulose fibre substrate have been characterised accordingly. The resultant cellulose fibre/conducting polymer hybrids have applications on their own (e.g. antistatic and chemical sensing papers), or can also be incorporated into other host materials (conventional polymer sheeting and extrusions) thereby adding new functionality due to the polymer coated fibres.

Additionally, by utilising the redox active surface of the fibre's polymer coating, silver metal nanoparticles may be incorporated into the composite. Electrochemical deposition of metals on electrodes by conducting polymers such

as PPy and PAn has been well studied.[7–13] Electroless deposition for the recovery of metals has also been reported in which polymer films are oxidised by metal ions of relatively high oxidation potential, effectively reducing the metal to its neutral form. Silver,[14–16] gold[17] and palladium[18–19] have proved successful in this procedure.

This paper outlines an electroless deposition method of metal recovery, whereby silver from solution is reduced, from $Ag^+$ to $Ag^0$, by an oxidised form of the polymer coating. The removal of silver ions from aqueous media indicates the potential application of conducting polymer composites for the recovery of noble metals or in wastewater treatment. Furthermore, through the incorporation of silver, the fibre/polymer composites possess an inhibitory action against bacterial growth. Thus, future applications of such materials may include antimicrobial papers. To the best of our knowledge, this is the first report of the preparation and characterisation of cellulose/conducting polymer/silver hybrid materials.

## 2.Results and Discussion

### 2.1 Conducting Polymer/Cellulose Hybrid Materials

Neat Kraft paper fibres are white, approximately 2.5 to 3.0 mm in length and with a fibre diameter of approximately 30 to 40 μm. The fibres have a relatively smooth surface (Figure 1), but at higher magnifications individual micro-fibrils (indicated by arrows) unwinding from the parent fibre can be observed. Composites based on PPy yielded black fibres of Kraft paper, with each fibre being individually coated with the PPy polymer. The surface morphology of a cellulose fibre/PPy composite is shown in Figure 2. With increasing magnification, it is seen that the PPy coating comprises small uniform spheres about 100 to 150 nm in diameter which are fused together to fully encapsulate the fibre. The polymer coating closely follows the original morphology of the fibres such that even individual fibrils of the parent paper fibre are entirely encapsulated, but remain discernible.

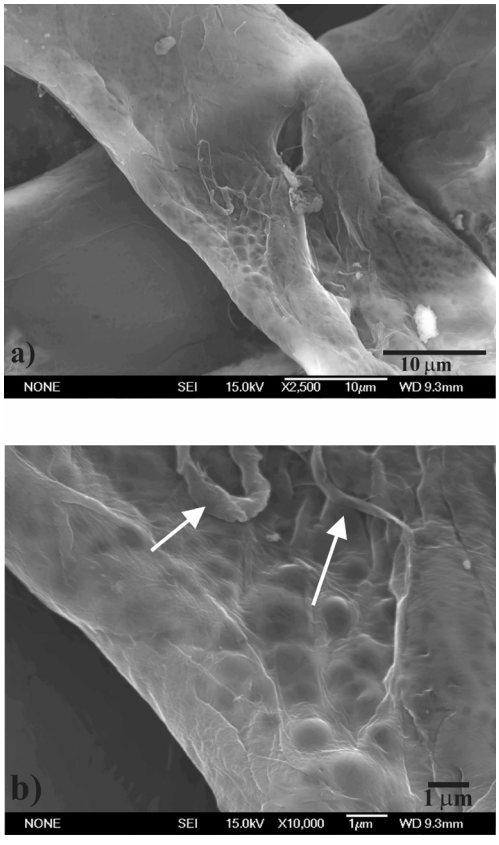

Figure 1. a) Neat cellulose fibres, 2500 times magnification; b) indicating unwinding micro-fibrils, 10000 times magnification.

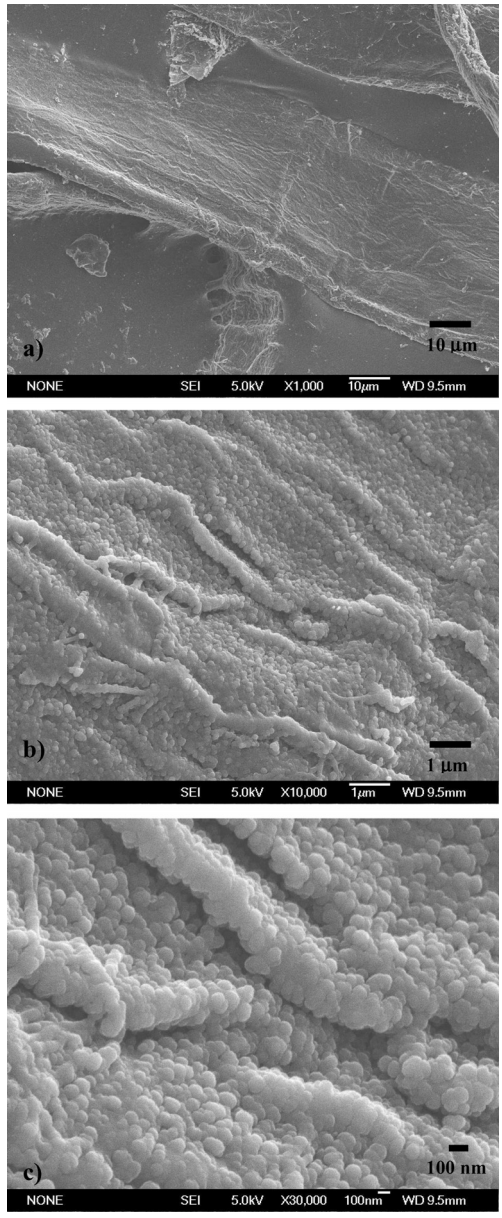

Figure 2. a)–c) Electron microscope images showing increasing magnifications of a paper fibre/polypyrrole composite ($FeCl_3$ as oxidant).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

When ferric chloride was employed as the oxidising agent in the preparation of fibre/PAn composites, the polymer coating resulted in the emeraldine salt form. Conversely, when the oxidant utilised was ammonium persulfate the resulting PAn coating was in the emeraldine base form. These results were implied by the respective green and blue colours observed and confirmed by UV/Vis spectroscopy. Composites of PAn similarly exhibit a polymer coating wherein the fibres are fully encapsulated yet the underlying morphology and micro-fibrils remain similarly clearly distinguishable. The average size of the polymer spheres of PAn is observed to be smaller than those of PPy, approximately 50 to 100 nm in diameter (Figure 3).

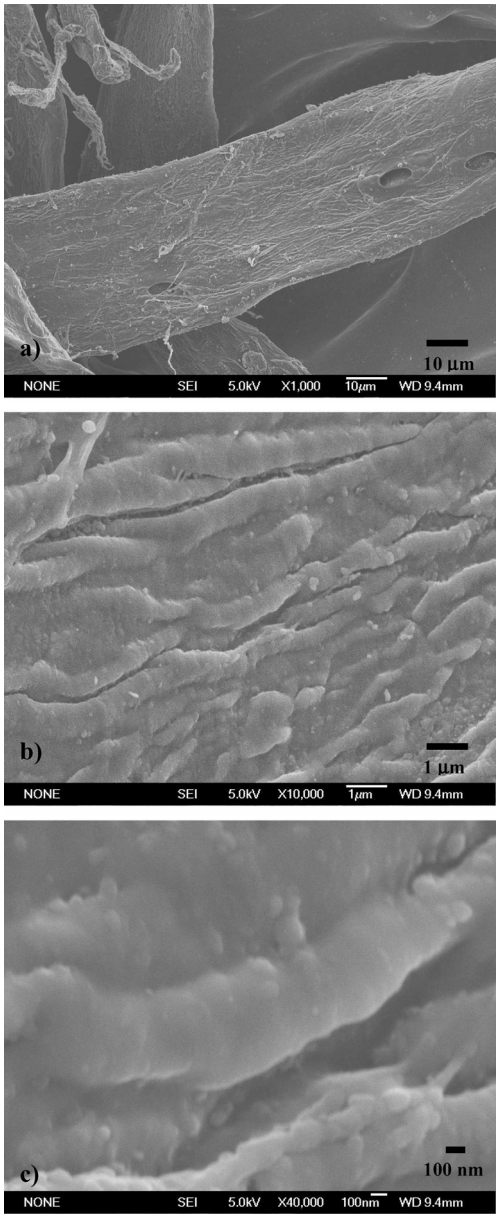

Figure 3. a)–c) Electron microscope images showing increasing magnifications of a paper fibre/polyaniline composite ($FeCl_3$ as oxidant).

## 2.2 Cyclic Voltammetry

Cyclic voltammetry was used to determine the electrochemical transitions of the fibre composites and to ascertain their thermodynamic stability. The cyclic voltammograms for the cellulose/polymer composites, despite being dissimilar from their corresponding electrochemically synthesised free polymers, still showed transitions from reduced to oxidised forms. This demonstrates that the important redox feature of conducting polymers was retained in the preparation of the composites.

When the scan rate of the cyclic voltammograms for the free polymer was altered, from 10 to 50 $mV s^{-1}$, the positions of the peaks representing the electrochemical transitions remain unchanged. This implies that the polymers themselves are thermodynamically stable and the kinetics of the redox transitions are faster than the scan speeds used in the measurements. It also indicates that there is only one method of electron transport in the free polymer.

When repeating these measurements for the fibre/polymer composites, the position of the redox peaks relating to the respective electrochemical transitions change as the scan speed is altered (Figure 4). Additionally, the transition peaks from emeraldine to pernigraniline and the reverse are not observed. This may indicate two things.[20–21] Firstly, the specific transition that yields the redox peak in the particular voltammogram is either not thermodynamically stable or the kinetics of the redox transition are slower than the scan rates. Secondly, contact between the fibres and the electrode may not be ideal. However, the first explanation is preferred as the expected colours and changes in the UV/Vis spectra for the transition from emeraldine (blue) to pernigraniline (purple) are indeed observed.

As both the substrate and the polymer are themselves thermodynamically stable, the change in peak position relating to these electrochemical transitions with changing scan speeds also implies that there is chemical bonding between the polymer and the underlying fibre with a complex electron interaction. The interaction between the substrate and the coating presumably gives rise to alternative and slower pathways for the electron transfer in the redox processes taking place in the fibre/polymer composite.

## 2.3 X-ray Photoelectron Spectrometry

The nature of the chemical bond between the cellulose-fibre substrate and polymer coating, inferred by cyclic voltammetry is further elucidated by XPS. Previous studies have suggested that the bond between polymer and cellulose substrates exists in the form of hydrogen bonding.[22,23] For cellulose composites with PAn and PPy, this implies that there is an interaction between nitrogen-bound hydrogen atoms (NH) on the polymer chain backbone and the lone pairs of electrons of the surface hydroxy (OH) groups of cellulose. This bonding may be in conjunction with, or may be substituted by, bonding between the hydrogen (H) of the surface OH groups of cellulose and the free electron pair of nitrogen (N) atoms in the polymer backbone.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

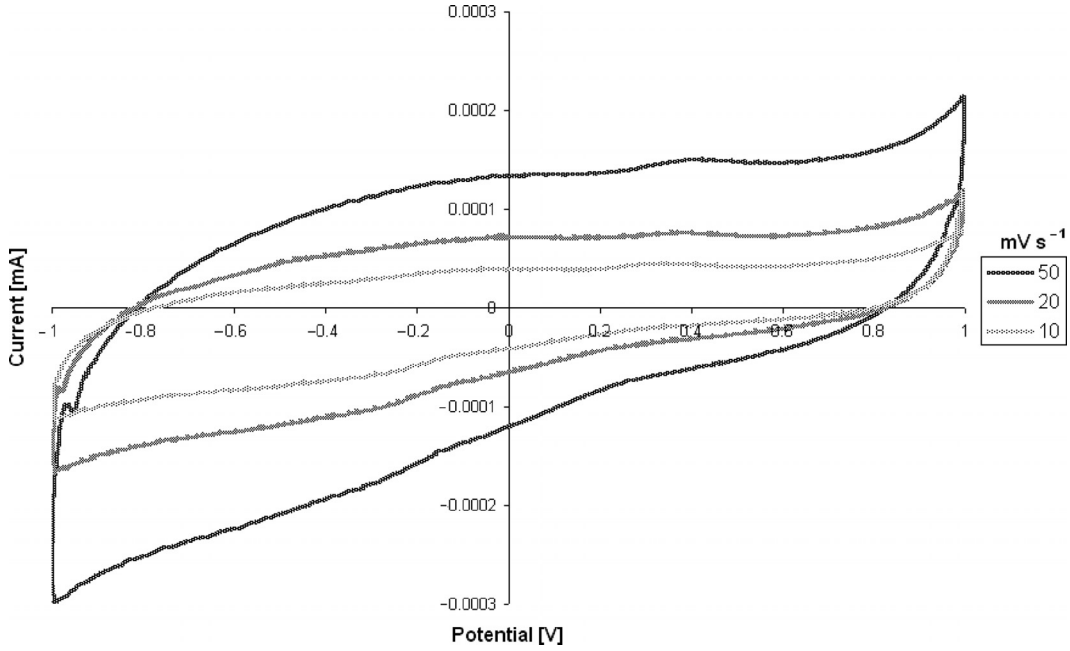

Figure 4. Cyclic voltammograms of paper/polyaniline composite ($FeCl_3$ as the oxidant) at different scan speeds.

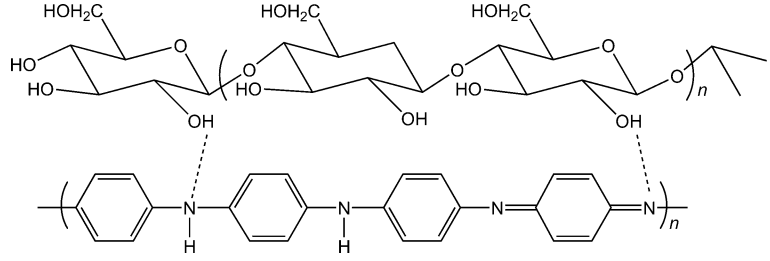

Figure 5. Possible bonding of cellulose to polyaniline.

XPS analyses carried out reinforce the suggestion that the chemical bonding is, in fact, hydrogen bonding between the nitrogen lone pairs of the polymer coating with the OH groups of the underlying cellulose substrate (Figure 5). This is shown by the oxygen XPS spectrum for the cellulose/PAn composite (Figure 6, b), in which there are distinct changes when compared to the same spectra for free cellulose fibres (Figure 6, a).

Of specific importance, is the appearance of a shoulder associated directly with C–OH bonding to N in the O 1s spectrum for the cellulose/PAn composite (Figure 6, b). The shift in the primary O 1s peak relating to C–OH bonds, from 533.3 to 530.6 eV for cellulose and the PAn-coated analogue, respectively, further indicates the presence of a chemical interaction between OH and N. The binding of the hydroxyl groups of cellulose to nitrogen lone pairs of PAn would result in lowering the binding energy of the oxygen from which the attached hydrogen atoms are being delocalised. This is supported by studies on oxygen binding for cellulose published by Wagner et al.[24]

The XPS spectrum for nitrogen for the cellulose/PAn composite was poorly resolved. However, the position and line width of the peak is comparable to that provided by Rodrigues et al.[25] for the N 1s spectrum of PAn bound to

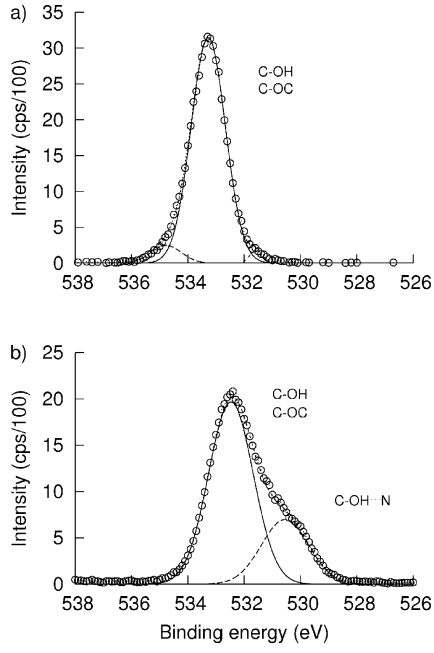

Figure 6. XPS spectra for (a) O 1s for cellulose; (b) O 1s for cellulose/polyaniline composite.

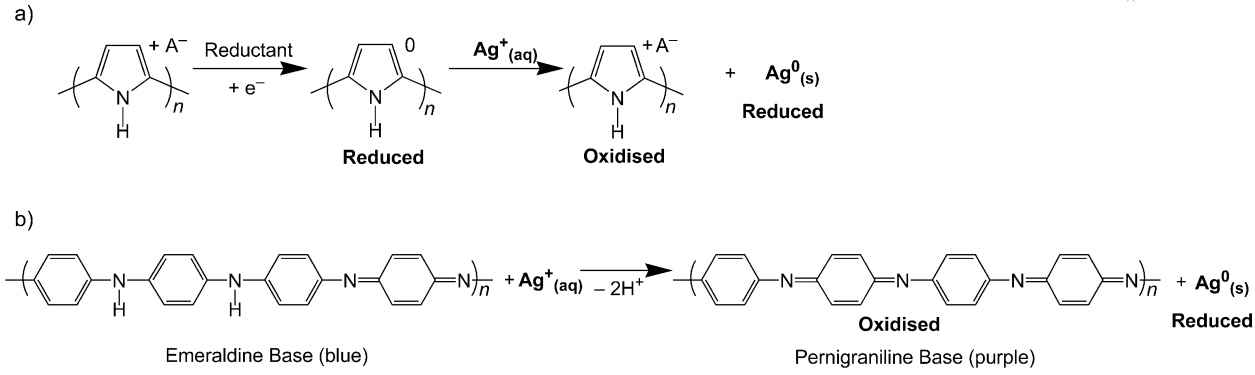

Figure 7. Chemical reduction of $Ag^+$ to $Ag^0$ by polypyrrole (a) and polyaniline (b).

lignin. On this basis it can be assumed that both imine and amine groups are present on the composite surface and that the mode of bonding is similar, whereby PAn binds from the nitrogen lone pairs through to the OH groups of cellulose rather than OH groups of lignin.

### 2.4 Fibre/Conducting Polymer/Silver Composites

A scheme of the reduction processes of silver ions by PPy and PAn, respectively, is shown in Figure 7. Under ambient conditions, PPy exists in an oxidised form due to atmospheric oxygen. Thus, PPy composites were first reduced by treatment with the reducing agent sodium borohydride. Upon addition of silver nitrate PPy is re-oxidised, therefore chemically reducing ionic silver to silver metal, which is deposited on the surface of the polymer.

Under ambient conditions PAn exists in its half-oxidised, emeraldine, form. Thus, by placing emeraldine base PAn/fibre composites directly into a silver nitrate solution, the polymer surface is oxidised to pernigraniline base, effectively reducing silver ions on the polymer surface to metallic silver. The redox reaction was noted by a colour change of the fibres from blue (emeraldine base) to purple (pernigraniline base).

Energy dispersive spectroscopy (EDS) was employed to determine the chemical composition of the surface of the fibre/polymer/silver composites. Figure 8 presents a secondary electron SEM image together with EDS representative of silver (lower levels of silver denoted with black, high levels of silver denoted with grey) for fibre/PAn/silver composites. As indicated by these images, a uniform coating of silver exists across the surface of the fibre polymer composites. The same is observed for the fibre/PPy composites.

SEM imaging of silver composites at higher magnifications shows the silver is present as individual nanoparticles (Figure 9). The greater spatial resolution of the SEM images shows that, although silver metal is distributed evenly across the polymer surface, the coating is not complete as implied by the lesser resolution of the EDS elemental maps.

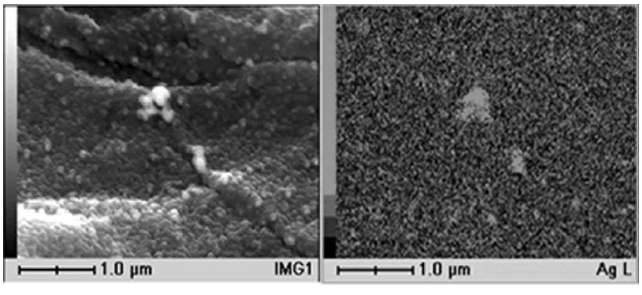

Figure 8. EDS overlay of C and Ag for cellulose fibre/polypyrrole/silver composite.

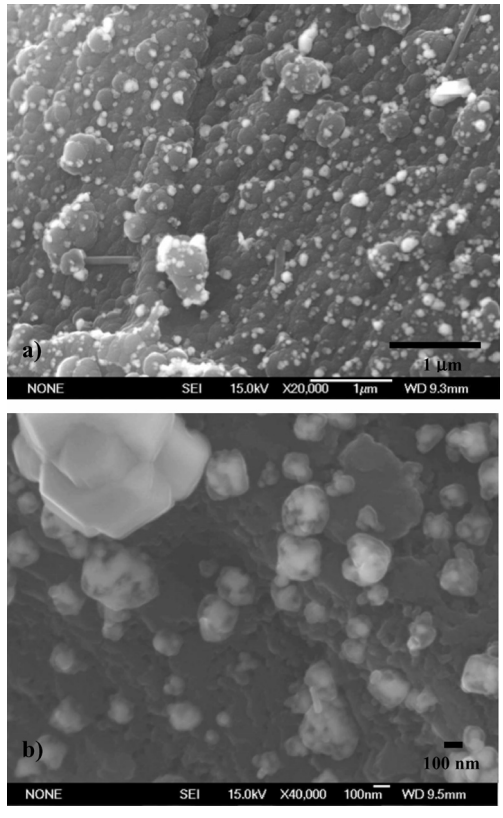

Figure 9. a)–b) Individual particulates of silver on the surface of a cellulose fibre/polypyrrole/silver composite at increasing magnification.

### 2.5 Electrical Conductivity

The Van der Pauw method was used to measure the electrical conductivities of the cellulose fibre/polymer hybrids

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

produced. The calculated conductivities ranged from $5.6 \times 10^{-4}$ S cm$^{-1}$ to $6.0 \times 10^{-4}$ S cm$^{-1}$ for PAn composites and $2.1 \times 10^{-3}$ S cm$^{-1}$ to $2.6 \times 10^{-1}$ S cm$^{-1}$ for PPy composites. The conductivity of single cellulose fibres has been measured as $0.1 \times 10^{-6}$ S cm$^{-1}$ at 50% relative room humidity.[26] Thus, this considerable increase in electrical conductivity from insulating to weak semiconductivity is indeed significant. Therefore, substantial opportunities exist for the development and application of conducting papers and packaging products from these materials. By incorporation into plastic materials the electrical conductivity (antistatic), redox properties (chemical sensing) and tensile strength can be imparted to the host plastic.

Interestingly, an increase in conductivity was not observed for the silver-coated composites. This may be attributed to silver being deposited on the surface in the form of individual nanoparticles (Figure 9) with poor electrical contact between particles. Conductivities were in fact seen to be lower for silver-coated composites compared to their polymer counterparts (Table 1). Contributing to the apparent decrease in conductivity may be the removal of the $Cl^-$ dopant and/or the lesser conductivity of the oxidised form of the underlying polymer due to a reduction in the electron transfer along the polymer backbone due to the chemical reduction of silver onto its surface.

Table 1. Electrical conductivities of merino cellulose fibre/polymer composites.

| Description | Conductivity [S cm$^{-1}$] | Potential oxidation state of polymer |
|---|---|---|
| PPy/Cellulose | $2.6 \times 10^{-1}$ | reduced |
| PPy/Cellulose/Ag | $3.8 \times 10^{-4}$ | oxidised |
| PAn/Cellulose | $6.0 \times 10^{-4}$ | emeraldine |
| PAn/Cellulose/Ag | $3.6 \times 10^{-9}$ | pernigraniline |

### 2.6 Antimicrobial Testing

For all samples, the silver-coated composites actively inhibited the growth of *Staphylococcus aureus* microbes and hence tested positive for their antimicrobial activity. White, hazy areas indicate bacterial growth, whereas the more transparent circles surrounding the fibre/polymer/silver composites, in the agar, indicate bacterial-free regions, i.e. zones of inhibition (Figure 10).

Silver is thought to migrate from the surface of the fibre composite inhibiting the growth of microbes in its path. The extent of silver-induced antimicrobial activity is directly proportional to ionic silver concentration.[27] Hence, the greater the silver ion concentration, the greater the antimicrobial efficacy will be. The release rate of unbound, free silver ions may therefore be correlated with the antimicrobial activity of the composite materials. As the zone of inhibition is similar for the fibre/PAn/silver and fibre/PPy/silver composites it can be assumed that the concentrations of silver across the surface of the composites are relatively similar. The release mechanism, which is deemed to be the same for all composites investigated, will theoretically be the limiting factor. This will also determine the effective lifetime of the antimicrobial activity. As the silver is strongly tethered to the polymer/fibre surface, this activity period will be desirably long.

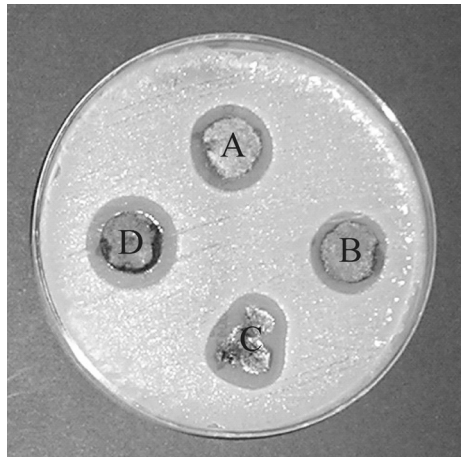

Figure 10. Zones of inhibition of *Staphlococcus aureus* microbial growth; cellulose fibre/polypyrrole/silver composites (A and B), cellulose fibre/polyaniline/silver composites (C and D).

## 3. Conclusions

New hybrid materials of cellulose fibres with conducting polymers have been successfully produced, in which individual Kraft fibres have been fully encapsulated by PPy and PAn spheres fused together in a continuous sheet to coat the fibres in their entirety. The bond between the fibre substrate and polymer coating is believed to be hydrogen bonding between the respective polymer (NH, N) and the OH groups of the cellulose on the fibre surface. The electrical conductivity of the prepared hybrid materials increased substantially from that of Kraft paper pulp, with conductivities as high as $2.6 \times 10^{-1}$ S cm$^{-1}$. Fibre/conducting polymer/silver composites were also successfully produced by utilising the redox capability of the polymer surface. The conductivities for the silver analogues decreased compared with the fibre/polymer hybrids. This is likely due to poor electrical contact between adjacent silver nanoparticles, as indicated by findings from scanning electron microscopy, and the lesser conductivity of the underlying oxidised polymer. Silver composites tested positive in their antimicrobial activity against *Staphylococcus aureus*. The conducting polymer/cellulose fibre composite products and their silver analogues can be used in plastics and packaging materials, whereby the unique properties of the composites, such as redox, electrical conductivity and antimicrobial properties, can be imparted to these materials thereby adding important functionality to them.

## 4. Experimental Section

### 4.1. Reagents and Equipment

Kraft paper pulp, produced from bleached *P. radiata*, was obtained from Carter Holt Harvey NZ. All chemicals employed were of ana-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

lytical grade and used as received unless otherwise stated. Pyrrole (Pyr, 97%) and aniline (Ani, 99%) monomer were purchased from Aldrich Chemicals, as were *p*-dodecyl benzyl sulfonate and ferric chloride. Aniline and pyrrole were distilled twice prior to use. Ammonium persulfate was obtained from Koch-Light Laboratories Ltd.

The morphology of the fibre/polymer/silver hybrids were characterised utilising a JEOL 6500 F field-emission gun scanning electron microscope. The redox properties of the conducting polymer/fibre composites were measured by cyclic voltammetry, comprising an Amel 7050 potentiostat and Junior Assist software. Fibre composites were attached to the electrode using Parafilm®. After soaking in the degassed conductive potassium perchlorate/perchloric acid (pH = 2) solution for 30 min the connection was tightened, ensuring ample contact between the sample and the electrode, and measurements were carried out. X-ray photoelectron spectroscopy (XPS) measurements were carried out using a Kratos Axis Ultra system with an aluminium filament operating at 10 mA and 15 kV using the $K_\alpha$ line. The pass energy for the survey scans was 160 eV and 10 eV for the narrow scans, and the sample area 300 × 700 μm. The binding energies were calibrated using the C–C 1s photoelectron peak at 285.0 eV. Conducting polymer-coated cellulose fibres were pressed into discs, using IR pellet-making apparatus, and their direct current (DC) electrical conductivity analysed by the Van der Pauw method for determining the conductivity for pressed discs and irregularly shaped samples.

### 4.2 Preparation of Conducting Polymer/Cellulose Fibre Hybrid Materials

Conducting polymer/cellulose fibre hybrids, using individual fibres of Kraft pulp, were prepared by the following method: Kraft pulp (0.5 g of 1 $cm^2$ pieces) was mixed with distilled water (100 $cm^3$) in a blender to give a fully dispersed suspension of individual pulp fibres. The resultant suspension was filtered by Büchner filtration and the fibres re-dispersed, with stirring, in a solution of pyrrole or aniline monomer (0.5 M) and *p*-dodecylbenzyl sulfonate (0.05 M) in water (200 $cm^3$). Stirring for approximately 1 h allowed for the monomer to be absorbed onto the surface of individual cellulose fibres. Then the fibres were filtered and washed with further monomer solution (0.5 M, 100 $cm^3$) and added to the oxidant, ferric chloride or ammonium persulfate (0.5 M, 100 $cm^3$). Polymerisation ensued, noted by a change in colour from orange to dark green to black, over a time period of approximately 5 min. However, the solution was left for a further 3 h to ensure complete polymerisation.

The resultant conducting polymer-coated cellulose fibres were filtered and washed on a 100 μm sieves with water and then subjected to repeated sonication with ethanol. This procedure was repeated several times in order to remove any excess and unbound polymer. Then the hybrid fibres were washed with hydrochloric acid (1.0 M) to effect doping with $Cl^-$ ions, followed by further washing with water. The resulting fibres were air-dried to give individual conducting polymer-coated cellulose fibres, which were black in colour.

### 4.3. Preparation of Fibre/Conducting Polymer/Silver Composites

A silver coating was deposited on the surface of the polymer-coated fibres by chemical reduction of $Ag^+$ to $Ag^0$. In the case of PPy/fibre composites, the polymer coating was first reduced in the presence of excess reducing agent ($NaBH_4$, 2.0 M in triethylene glycol dimethyl ether), and the resulting fibres filtered and washed quickly with water to remove residual reductant. Then the reduced polymer fibres were suspended in $AgNO_3$ (0.1 M, 100 $cm^3$), allowed to react with the $Ag^+$ ions and then washed, filtered and sonicated in ethanol to remove excess $Ag^+$ and $Ag^0$.

A reducing agent was unnecessary for the reduction of silver on the surface of PAn/fibre composites. PAn composites in the form of emeraldine base were added directly to $AgNO_3$ (0.1 M, 100 $cm^3$). The redox reaction ensued in which emeraldine base was oxidised to pernigraniline, thus simultaneously reducing $Ag^+$ to $Ag^0$ at the surface of the coated fibre (see part b of Figure 7, section 2.4). The oxidation reaction was noted by a colour change from blue (emeraldine base) to purple (pernigraniline base). The resultant fibres were similarly washed with distilled water, filtered and then sonicated in ethanol to remove excess silver.

# Ruthenium-Based NHC-Arene Systems as Ring-Opening Metathesis Polymerisation Catalysts

Nele Ledoux,*[a] Bart Allaert,[a] and Francis Verpoort[a]

**Keywords:** Carbene ligands / Homogeneous catalysis / Olefin polymerisation / Ruthenium

The availability of starting materials, the complexity of the preparative routes and the cost to make the catalyst are key in the development of industrially relevant olefin metathesis catalysts. With this in mind, new synthetic routes, which lead to alternatives for the classic ruthenium benzylidene complexes and circumvent the need for patented Grubbs intermediates were explored. The research presented herein focuses on the coordination of "saturated" N-heterocyclic carbene (NHC) ligands to Ru dimer [(*p*-cymene)$RuCl_2$]$_2$. As the coordination of the standard NHC ligand $H_2$IMes (1,3-dimesityl-4,5-dihydroimidazol-2-ylidene) was found to be unattainable, bidentate NHC analogues were synthesized instead. These are *O*-hydroxyaryl-substituted NHCs, capable of binding with the metal centre through the oxygen atom as well as through the carbene carbon atom. Their chelating properties improved the stability of the corresponding ruthenium arene complexes, which allowed more successful isolation.

## Introduction

Olefin metathesis is a fundamental catalytic process and stands among the most prominent ways to build carbon–carbon bonds.[1–6] The reaction consists of the cleavage and reformation of alkene double bonds with a simultaneous exchange of substituents. Cross metathesis (CM),[7,8] ring-closing metathesis (RCM),[9] ring-opening metathesis polymerisation (ROMP)[10] and acyclic diene metathesis polymerisation (ADMET),[11] illustrate the versatility of the olefin metathesis reaction. Thanks to the continuous improvement of its initiators and a sharpened comprehension of its reaction mechanism,[12–30] the olefin metathesis transformation has been upgraded to a very practical, efficient and flexible synthetic methodology. Olefin metathesis now allows cleaner, more efficient and less expensive industrial production of polymers, fine chemicals, pesticides and pharmaceutical intermediates. Despite the recent advances, the search for commercially relevant catalyst systems remains challenging. When thinking of commercial applications, one should not only focus on catalyst activity, selectivity or stability, as highly developed initiators are sometimes too expensive for applications on an industrial scale. Other important aspects are the availability of the starting materials, the complexity of the preparative routes and the cost to make the catalyst. In addition, it is often relevant to search for patent-free synthetic strategies. Up to now, most synthetic pathways toward Grubbs 2nd generation complexes, of which catalyst **1** is the most popular, proceed through bis(phosphane) benzylidene systems.[31,32] A more direct pathway with the use of moderate reaction conditions and readily available starting materials is quite desirable. This also involves the need for alternative means to introduce the alkylidene moiety, which avoid the quite cumbersome preparative routes by diazo compounds.[33] In this context, the Ru dimer [(*p*-cymene)$RuCl_2$]$_2$ (**2**) is air and moisture stable, and it is an easy to handle precursor that is an ideal starting material for the synthesis of allenylidene or vinylidene catalysts to be used for metathesis.[34–44] In order to find a resembling alternative for the classic Grubbs catalyst **1**, it would be necessary to coordinate $H_2$IMes (1,3-dimesityl-4,5-dihydroimidazol-2-ylidene) to Ru dimer **2**. Whereas several groups claim to have synthesized [(*p*-cy-

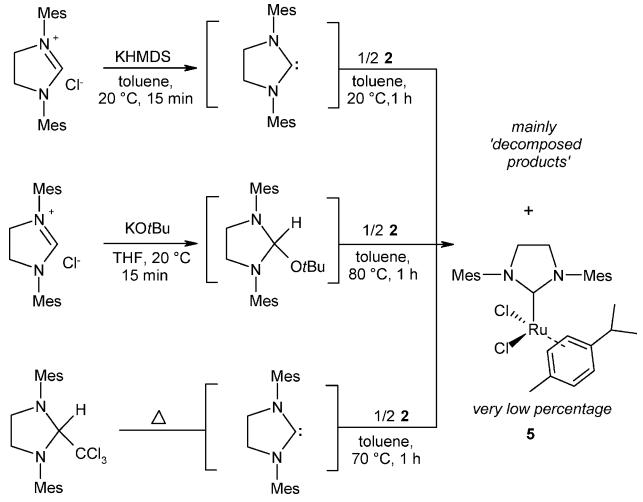
mene)($H_2$IMes)Ru$Cl_2$] in situ, it was never isolated, nor fully characterized.[45,46] Driven by the fascinating challenge to find alternative synthetic strategies, we herein describe the endeavour we undertook to contribute to this quest.

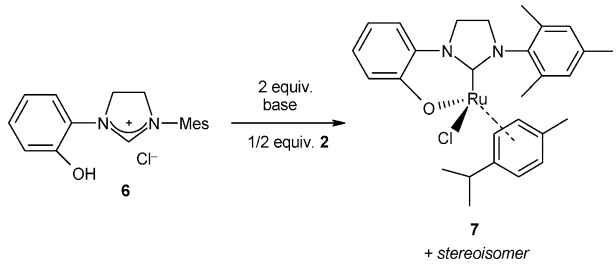
## Results and Discussion

Whereas the coordination of IMes (1,3-dimesitylimidazol-2-ylidene) to Ru dimer **2** proceeds readily by standard synthetic strategies (complex **4**),[38,47] analogous binding of $H_2$IMes was found to be more problematic. Regardless of the reaction conditions applied, a mixture of Ru complexes was obtained (Scheme 1). Only when the chloroform adduct $H_2$IMes(H)($CCl_3$) was used as a carbene precursor could a small rate of N-heterocyclic carbene (NHC) coordination be evidenced through $^{13}$C NMR spectroscopy. A $^{13}$C NMR resonance was found at $\delta$ = 202.5 ppm, which is characteristic for the carbene carbon atom coordinated to the metal centre. However, $^1$H NMR spectroscopic analysis of the reaction products revealed that desired complex **5** was only formed as a minor product together with undefined hydridic species. $^1$H NMR spectroscopic resonances were found at $\delta$ = –3.64, –3.98, –5.09 and –5.62 ppm.



Scheme 1. Synthesis of [(*p*-cymene)($H_2$IMes)Ru$Cl_2$].

Because the failure in our efforts to isolate **5** was assigned to a lack of stability of the complex, a bidentate analogue of the NHC ligand was synthesized. The chelating properties of a bidentate NHC were expected to ameliorate the complex stability through a "chelate effect". The synthesis of 1-(mesityl)-3-(2-hydroxyphenyl)-4,5-dihydroimidazolium chloride salt (**6**) was straightforward following a procedure outlined by Grubbs et al.[48] In order to effectuate ligand coordination, the NHC precursor was treated with 2 equiv. of base; that is, 1 equiv. to liberate the free carbene and 1 equiv. to deprotonate the phenolic group. After 15 min of reaction time, Ru dimer **2** was added to the reaction mixture. As expected, the ligand bound to the metal centre in a chelating manner (Scheme 2). Because of the pseudotetrahedral arrangement of the ligands, a stereogenic centre was created at the Ru centre, leading to the existence of two stereoisomers. Complex **7** shows high stability and can be handled in air without any sign of decomposition. To explore its thermal stability, a solution of **7** (16.5 mg, 0.030 mmol) and coronene (internal standard, 9.0 mg, 0.030 mmol) in deuterated chlorobenzene ($C_6D_5Cl$, 0.50 mL) was followed over time at 100 °C by using $^1$H NMR spectroscopy. After 48 h, no sign of decomposition was observed. At 120 °C, the complex fully decomposed within 4 h.



Scheme 2. Synthesis of NHC-arene complex **7**.

Dark-red crystals of **7** suitable for X-ray structure analysis were grown by slow evaporation of a toluene/$CH_2Cl_2$ solution, and its molecular structure is represented in Figure 1. The molecular species consists of a *p*-cymene ligand showing $\eta^6$-bonding, an anionic chloride ligand and a bidentate (C,O) chelating NHC ligand. The isopropyl group on the arene ligand is a little distorted away from the metal centre as a result of steric factors.

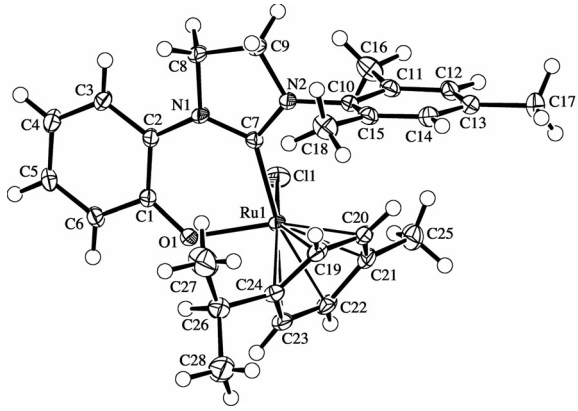


Figure 1. The molecular structure of **7**; ellipsoids show 50% probability.

The catalytic activity of **7** was evaluated in the ROMP of the highly strained monomer norbornene and compared to the activity of Ru dimer **2**, complex **3** and **4** (Table 1). Our results reveal that **7** displays very poor activity in metathesis reactions; only 20% of norbornene polymerised during a reaction time of 3 h at 85 °C (Table 1, Entry 4). It has been described in the literature that for this catalyst type decomplexation of the arene ligand is the prior requirement for the generation of catalytic activity.[49–52] The complex must be coordinatively unsaturated for a substrate to enter the coordination sphere of the metal. In other words, for the catalyst to become active, a ligand has to dissociate to generate a vacant site. However, the high stability of complex **7** indicates that arene ligand dissociation is greatly restrained.

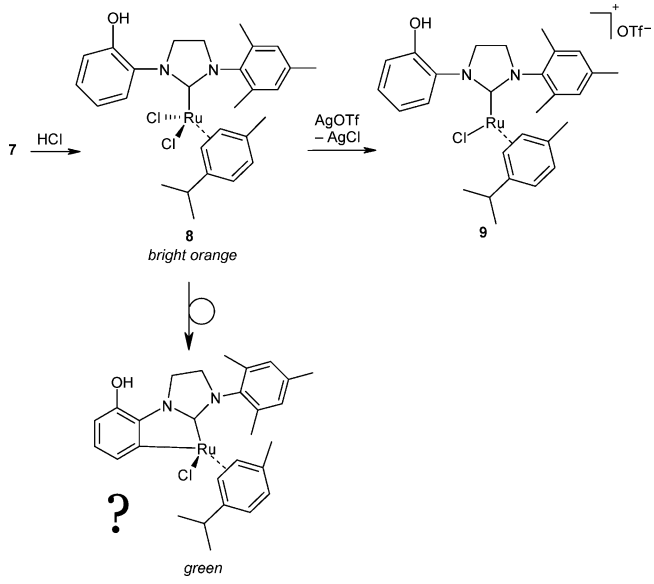
| 8 | **9** | 16 | 1112 | 2.6 | 78 |
| 9 | **10** | 4 | – | – | – |
| 10 | **10** + phenylacetylene | 7 | 32 | 3.1 | 42 |
| 11 | **10** + TMSD | 10 | 65 | 4.5 | 65 |
| 12 | **11** | 14 | 932 | 2.1 | 61 |

[a] Catalyst/norbornene, 1:2500, cat. conc. = 0.41 mM, 85 °C, solvent = 0.5 mL of $CH_2Cl_2$ to dissolve the catalyst + 10 mL of toluene, reaction time = 3 h. A correction factor of 0.5*Mn was applied for characterizing the PNBs by gel permeation chromatography.[53] The *cis* fraction was determined by $^1$H NMR spectroscopy: $\delta$ = 5.36 CH=CH *trans*, 5.22 CH=CH *cis*.

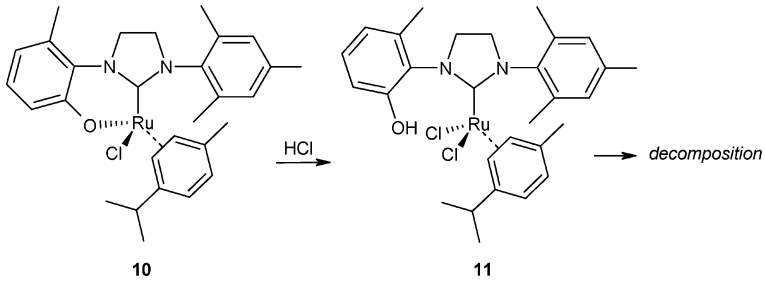
With the aim to generate the vinylidene moiety in situ, an excess amount of phenylacetylene (20 equiv.) was added to the catalyst (Table 1, Entry 5). Only a minor activity enhancement was observed. Also, the addition of (trimethylsilyl)diazomethane (TMSD), which is known to activate [(*p*-cymene)($PCy_3$)$RuCl_2$] (**3**) with the in situ formation of [$RuCl_2$(=$CHSiMe_3$)($PCy_3$)][49,54] did not significantly enhance the catalytic activity (Table 1, Entry 6). In a dissociative ligand substitution pathway, dissociation of the *p*-cymene moiety is a prerequisite for the generation of an empty coordination site where the alkylidene moiety can be introduced. As a result of the exceptional stability of the complex, which is accompanied by a low dissociation tendency of the arene ligand, the addition of a terminal alkyne or a diazo compound was found to have only a minor effect. Furthermore, we observed that in contrast to complexes of type **3** or **4**, which become more active towards metathesis upon UV irradiation,[35,51,55] the ROMP-catalyzed by **7** is not photoinduced, as no change in the outcome was seen when reactions were carried out in the dark or under constant irradiation with UV light (shortwave UV: 254 nm, longwave UV: 365 nm).

The addition of an excess amount of ethereal HCl to **7** caused protonation of the phenolic oxygen atom, therefrom affording complex **8** as a bright orange solid (Scheme 3). The OH proton was found at $\delta$ = 10.08 ppm as a broad $^1$H NMR ($C_6D_6$) spectroscopic signal. Through breaking of the chelate, the complex was expected to lose part of its extreme stability and become more reactive. Entry 7 in Table 1 shows that a loss of catalytic activity was observed instead! Also, cationic counterpart **9** exhibited poor ROMP activity (Table 1, Entry 8). As expected, losing the chelate effect induced a significantly decreased stability of complex **8**. The complex was found to decompose rapidly in solution. Even as a solid stored under inert atmosphere the complex was unstable and slowly changed colour from orange to green (time course of two weeks). NMR spectroscopic analysis of the decomposition product indicated that both NHC and *p*-cymene ligand were still coordinated to the Ru centre. Therefore, we suggest that **8** suffers from a tendency to undergo *ortho* metallation with the 2-hydroxyphenyl amino side group.[46,56–58]



Scheme 3. Losing the chelate effect.

Anticipating that this *ortho* metallation might be avoided by a small modification in the NHC framework, a methyl unit was introduced at the carbon atom in the *ortho* position of the 2-hydroxyphenyl group. Coordination of the new bidentate NHC afforded air- and moisture-stable complex **10**. Also, this complex is a poor initiator for metathesis and the addition of a terminal alkyne or TMSD group only slightly increases the polymer yield (Table 1, Entries 9–11).



Scheme 4. Modified complexes **10** and **11**.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Again, HCl was added to "break" the chelate to afford complex **11**. Thereupon the catalytic activity in the ROMP of 2-norbornene was slightly enhanced (Table 1, Entry 12). In spite of the small ligand modification (*ortho* methylation), also this complex was found to slowly decompose. A solution of **11** in $CH_2Cl_2$ changed colour from orange to dark green during a time course of 1 h. Unfortunately, a complex mixture of products was obtained, and we were not able to identify the decomposition products (Scheme 4).

## Conclusions

From these results, it is clear that complexes of the type [(*p*-cymene)(L)$RuCl_2$] (with L = $H_2$IMes or resembling NHC) are not very reactive, and they too unstable for practical use. Likely due to stability problems, we were unable to isolate complex [(*p*-cymene)($H_2$IMes)$RuCl_2$] (**5**). Similar complexes **8** and **11** were successfully isolated, but only when an uncommon synthetic strategy was followed. The NHCs were first introduced as bidentate ligands, which greatly enhanced the stability of the complex through the chelate effect. Subsequent treatment with hydrochloric acid caused a breaking of the chelate O–Ru bond and formation of complexes [(*p*-cymene)(NHC)$RuCl_2$] bearing monodentate NHCs. Upon loss of the chelate effect, a dramatic decrease in the stability of the complex was observed; as a result, complexes **8** and **11** could not be kept for more than a few days even when stored as a solid under an inert atmosphere. In solution, both complexes decomposed very rapidly, which drastically restricted their catalytic value. To adequately compete with the Grubbs catalysts, it is unquestionable that better activity and stability levels have to be reached. Therefore, our attention has now been drawn to other synthetic methods that first introduce an alkylidene moiety and then, in a second reaction step, realize the coordination of an NHC ligand. We hope to be able to report on these results in the near future.

## Experimental Section

**General:** All reactions and manipulations involving organometallic compounds were conducted in oven-dried glassware under an argon atmosphere by using standard Schlenk techniques. Solvents were dried with appropriate drying agents and distilled prior to use. $^1$H and $^{13}$C NMR spectroscopic measurements were performed with a Varian Unity-300 spectrometer. Ru dimer **2**,[59] $H_2$IMes(H)($CCl_3$),[60] the bidentate NHC salts[47] and complex **3**[35] were prepared according to literature procedures. (Trimethylsilyl)diazomethane (TMSD) was purchased from Aldrich as a solution in hexane. We were unable to do elemental analysis on complexes **9** and **11** because of the lack of stability of these compounds. For these two complexes, we hope that characterisation through $^1$H NMR and $^{13}$C NMR spectroscopy is sufficient.

**Synthesis of the Complexed**

**[(*p*-cymene)$RuCl_2$(IMes)] (4):** The synthesis of complex **4** was previously reported by Nolan et al. to result from the reaction of Ru dimer with free IMes carbene.[38] We herein describe a slightly altered synthetic strategy, which avoids the isolation and handling of the air- and moisture-sensitive free carbene. To a dry Schlenk flask charged with 1,3-bis(2,4,6-trimethylphenyl)imidazolium chloride (0.490 g, 1.44 mmol) and dry toluene (5 mL) was added LiHMDS (0.5 M in toluene, 2.88 mL, 1 equiv.). The resulting suspension was stirred at room temperature for 15 min. Ru dimer **2** (0.43 g, 0.70 mmol) was then added as a solid, and the mixture was stirred at room temperature for an additional 45 min. The solution was filtered to remove residual salts, and the filtrate was concentrated under vacuum. The residue was dissolved in a small amount of $CH_2Cl_2$ (1 mL) and precipitated upon addition of hexane (25 mL). The orange solid was filtered off and vacuum dried. Yield: 0.67 g, 78%. NMR spectroscopic data are similar to those reported by Nolan et al.: $^1$H NMR (300 MHz, $CDCl_3$): $\delta$ = 6.95 (s, 4 H, Mes-3,5-H), 6.90 (s, 2 H, NC*H*C*H*N), 5.03 (d, $J$ = 5.5 Hz, 2 H, *p*-cymene aryl-H), 4.63 (d, $J$ = 5.5 Hz, 2 H, *p*-cymene aryl-H), 2.51 (m, 1 H, *p*-cymene C*H*($CH_3$)$_2$), 2.35 (s, 6 H, mesityl *p*-C$H_3$), 2.23 (s, 6 H, mesityl *o*-C$H_3$), 1.79 (s, 3 H, *p*-cymene C$H_3$), 1.07 [d, $J$ = 6.8 Hz, 6 H, *p*-cymene CH(C$H_3$)$_2$] ppm. $^{13}$C NMR (75 MHz, $CDCl_3$): $\delta$ = 6.95 172.0 (N*C*N), 139.0, 138.9, 130.1, 128.9, 125.4, 103.1, 96.0, 87.0, 85.9, 30.4 [*p*-cymene *C*H($CH_3$)$_2$], 22.9, 22.7, 21.4, 19.3, 18.24, 18.0 ppm.

**NHC-Arene Complex 7:** The NHC precursor 1-mesityl-3-(2-hydroxyphenyl)-4,5-dihydroimidazolium chloride (0.765 g, 2.41 mmol) was treated with a solution of potassium hexamethyldisilazide (KHMDS; 0.5 M in toluene, 9.66 mL, 4.83 mmol, 2 equiv.) over 15 min at room temperature. A suspension of Ru dimer **2** (0.70 g, 1.14 mmol) in toluene was added, and the resulting mixture was stirred for an additional 1.5 h at room temperature. The toluene solution was filtered and washed with $CH_2Cl_2$ (2 × 10 mL). After evaporation of the filtrate, cold acetone was added while stirring. Subsequent filtration allowed the isolation of the pure red-pink catalyst, which was thoroughly dried. Yield: 0.58 g, 46%. $^1$H NMR (300 MHz, $CDCl_3$): $\delta$ = 6.93–7.02 (m, 3 H, aryl CH), 6.79 (t, $^3J_{H,H}$ = 7.3 Hz, 1 H, aryl CH), 6.71 (d, $^3J_{H,H}$ = 7.9 Hz, 1 H, aryl CH), 6.43 (t, $^3J_{H,H}$ = 7.3 Hz, 1 H, aryl CH), 5.52 (d, $J$ = 4.6 Hz, 1 H, *p*-cymene aryl-H), 5.26 (d, $J$ = 4.6 Hz, 1 H, *p*-cymene aryl-H), 5.09 (d, $J$ = 3.4 Hz, 1 H, *p*-cymene aryl-H), 4.43 (pseudo q, $J_{app}$ = ca. 10.5 Hz, 1 H, NC$H_2$C$H_2$N), 4.18 (pseudo q, $J_{app}$ = ca. 10.5 Hz, 1 H, NC$H_2$C$H_2$N), 4.02 (pseudo q, $J_{app}$ = ca. 10.5 Hz, 1 H, NC$H_2$C$H_2$N), 3.92 (pseudo q, $J_{app}$ = ca. 10.5 Hz, 1 H, NC$H_2$C$H_2$N), 3.69 (d, $J$ = 3.2 Hz, 1 H, *p*-cymene aryl-H), 2.50 (s, 3 H, mesityl C$H_3$), 2.42 (s, 3 H, mesityl C$H_3$), 2.41 [m, 1 H, *p*-cymene C*H*($CH_3$)$_2$], 2.33 (s, 3 H, mesityl C$H_3$), 1.58 (s, 3 H, *p*-cymene C$H_3$), 0.96 [d, $^3J_{H,H}$ = 6.7 Hz, 3 H, *p*-cymene CH(C$H_3$)$_2$], 0.83 [d, $^3J_{H,H}$ = 6.7 Hz, 3 H, *p*-cymene CH(C$H_3$)$_2$] ppm. $^{13}$C NMR (75 MHz, $CDCl_3$): $\delta$ = 202.7 (N*C*N), 157.4 (*C*-O), 139.7 (NHC aryl-C), 139.0 (NHC aryl-C), 138.0 (NHC aryl-C), 136.2 (NHC aryl-C), 130.9 (NHC aryl-C), 130.5 and 130.3 (NHC aryl-C), 128.9 and 128.8 (NHC aryl-C), 124.92 and 124.86 (NHC aryl-C), 121.3 and 121.2 (NHC aryl-C), 116.3 and 116.2 (NHC aryl-C), 113.9 and 113.8 (NHC aryl-C), 101.1 (*p*-cymene aryl-C), 95.2 (*p*-cymene aryl-C), 94.7 (*p*-cymene aryl-C), 93.1 (*p*-cymene aryl-C), 83.8 (*p*-cymene aryl-C), 79.4 (*p*-cymene aryl-C), 51.1 (*C*$H_2$C$H_2$), 48.7 (CH$_2$*C*H$_2$), 30.2 and 30.1 [p-cymene *C*H($CH_3$)$_2$], 23.3 (*C*$H_3$), 21.3 and 21.1 (*C*$H_3$), 20.0 and 19.8 (*C*$H_3$), 18.6 and 18.5 (*C*$H_3$), 18.3 and 18.1 (*C*$H_3$) ppm. *Some carbon atoms have a double peak in the spectrum, which indicates the presence of two diastereomers in roughly an equal ratio.* $C_{28}H_{33}ClN_2ORu$ (550.11): C 61.14, H 6.05, N 5.09; found C 61.39, H 6.08, N 5.12.

**NHC-Arene Complex 8:** Complex **7** (0.125 g, 0.227 mmol) was dissolved in $CH_2Cl_2$ (5 mL). An excess amount of HCl (1 N in $Et_2O$, 1 mL) was added, and the resulting mixture was stirred at room temperature for 5 min. Solvents were evaporated and hexane

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

(25 mL) was added to precipitate complex **8** as a bright orange solid. Yield: 0.12 g, 93%. $^1$H NMR (300 MHz, $CDCl_3$): $\delta$ = 8.02 (d, $J$ = 7.5 Hz, 1 H, aryl C*H*), 7.10 (s, 1 H, aryl C*H*), 7.03 (s, 1 H, aryl C*H*), 6.96 (m, 1 H, aryl C*H*), 6.89 (m, 2 H, aryl C*H*), 5.70 (br. s, 2 H, *p*-cymene aryl-*H*), 5.32 (br. s, 2 H, *p*-cymene aryl-*H*), 4.34 (m, 2 H, NC$H_2$C$H_2$N), 4.10 (m, 1 H, NC$H_2$C$H_2$N), 3.98 (m, 1 H, NC$H_2$C$H_2$N), 2.86 [sept, $J$ = 5.5 Hz, 1 H, *p*-cymene C*H*($CH_3$)$_2$], 2.58 (s, 3 H, mesityl C$H_3$), 2.38 (s, 3 H, mesityl C$H_3$), 2.35 (s, 3 H, mesityl C$H_3$), 1.75 (s, 3 H, *p*-cymene $CH_3$), 1.02 [m, 6 H, *p*-cymene CH(C$H_3$)$_2$] ppm. *Signals of the aromatic p-cymene protons appear as broad signals due to internal rotation of the ligand.* $^1$H NMR (300 MHz, $C_6D_6$): $\delta$ = 10.08 (br. s, 1 H, O*H*) ppm. $^{13}$C NMR (75 MHz, $CDCl_3$): $\delta$ = 203.0 (N*C*N), 146.1 (*C*-OH), 139.8 (NHC aryl-C), 138.8 (NHC aryl-C), 137.4 (NHC aryl-C), 135.5 (NHC aryl-C), 130.4 (NHC aryl-C), 129.5 (NHC aryl-C), 129.2 (NHC aryl-C), 125.1 (NHC aryl-C), 121.7 (NHC aryl-C), 118.9 (NHC aryl-C), 117.7 (NHC aryl-C), 105.0 (br., *p*-cymene aryl-C), 97.3 (br., *p*-cymene aryl-C), 92.1 (br., *p*-cymene aryl-C), 82.3 (br., *p*-cymene aryl-C), 52.0 (N*C*$H_2$C$H_2$N), 49.7 (N*C*$H_2$C$H_2$N), 30.4 [*p*-cymene *C*H($CH_3$)$_2$], 23.6 (*C*$H_3$), 21.3 (*C*$H_3$), 21.2 (*C*$H_3$), 19.8 (*C*$H_3$), 18.9 (*C*$H_3$), 18.5 (*C*$H_3$) ppm. $C_{28}H_{34}Cl_2N_2ORu$ (586.57): calcd. C 57.34, H 5.84, N 4.78; found C 56.62, H 5.79, N 4.54.

**Cationic NHC-arene Complex 9:** Silver triflate (0.049 g, 0.19 mmol) was added to a solution of **8** (0.109 g, 0.19 mmol) in $CH_2Cl_2$ (5 mL). The reaction mixture was stirred for 15 min at room temperature. The solution was filtered to remove AgCl, and the solvent was evaporated to almost complete dryness. The addition of hexane (10 mL) led to precipitation of the desired cationic complex as a bright orange solid, which was filtered off and dried in vacuo. Yield: 0.13 g, 96%. $^1$H NMR (300 MHz, $CDCl_3$): $\delta$ = 7.51 (d, $J$ = 5.1 Hz, 1 H, aryl C*H*), 7.08 (s, 1 H, aryl C*H*), 7.02 (m, 4 H), 5.75 (br. s, 2 H, *p*-cymene aryl-*H*), 5.43 (br. s, 2 H, *p*-cymene aryl-*H*), 4.53 (m, 1 H, NC$H_2$C$H_2$N), 4.28 (m, 1 H, NC$H_2$C$H_2$N), 4.09 (m, 2 H, NC$H_2$C$H_2$N), 2.59 (s, 3 H, mesityl C$H_3$), 2.47 [m, 1 H, *p*-cymene C*H*($CH_3$)$_2$], 2.36 (s, 3 H, mesityl C$H_3$), 2.33 (s, 3 H, mesityl C$H_3$), 1.63 (s, 3 H, *p*-cymene $CH_3$), 0.95 [m, 6 H, *p*-cymene CH(C$H_3$)$_2$] ppm. $^{13}$C NMR (75 MHz, $CDCl_3$): $\delta$ = 204.4 (N*C*N), 144.2 (*C*-OH), 139.9 (NHC aryl-C),138.8 (NHC aryl-C), 136.8 (NHC aryl-C), 135.5 (NHC aryl-C), 130.6 (NHC aryl-C), 129.4 (NHC aryl-C), 129.0 (NHC aryl-C), 125.7 (NHC aryl-C), 123.5 (NHC aryl-C), 118.4 (NHC aryl-C), 117.8 (NHC aryl-C), 91.8 (br., *p*-cymene aryl-C), 83.2 (br., *p*-cymene aryl-C), 52.1 (N*C*$H_2$C$H_2$N), 49.6 (N*C*$H_2$C$H_2$N), 30.6 [*p*-cymene *C*H($CH_3$)$_2$], 23.0 (*C*$H_3$), 21.2 (*C*$H_3$), 21.1 (*C*$H_3$), 19.9 (*C*$H_3$), 18.7 (*C*$H_3$), 18.2 (*C*$H_3$) ppm.

**NHC-Arene Complex 10:** In an analogous procedure as for complex **7**, 1-mesityl-3-(2-hydroxy-6-methylphenyl)-4,5-dihydroimidazolium chloride (0.284 g, 0.86 mmol), KHMDS (0.5 M in toluene, 3.43 mL) and Ru dimer **2** (0.25 g, 0.41 mmol) afforded complex **10** as an orange-red solid. Yield: 0.15 g, 32%. $^1$H NMR (300 MHz, $CDCl_3$): $\delta$ = 7.02 (m, 2 H, aryl C*H*), 6.84 (t, $J$ = 6.9 Hz, 1 H, aryl C*H*), 6.73 (d, $J$ = 7.3 Hz, 1 H, aryl C*H*), 6.46 (m, 1 H, aryl C*H*), 5.56 (d, $J$ = 6.3 Hz, 1 H, *p*-cymene aryl-*H*), 5.29 (br. s, 1 H, *p*-cymene aryl-*H*), 5.11 (d, $J$ = 5.0 Hz, 1 H, *p*-cymene aryl-*H*), 4.43 (pseudo q, $J$ = 10.5 Hz, 1 H, NC$H_2$C$H_2$N), 4.18 (pseudo q, $J$ = 10.1 Hz, 1 H, NC$H_2$C$H_2$N), 4.04–3.92 (m, 2 H, NC$H_2$C$H_2$N), 3.71 (br. s, 1 H, *p*-cymene aryl-*H*), 2.53 (s, 3 H, mesityl C$H_3$), 2.45 (s, 6 H, 2-hydroxy-6-methylphenyl and mesityl C$H_3$), 2.41 [m, 1 H, *p*-cymene C*H*($CH_3$)$_2$], 2.36 (s, 3 H, mesityl C$H_3$), 1.61 (s, 3 H, *p*-cymene $CH_3$), 0.98 [d, $J$ = 7.0 Hz, 3 H, *p*-cymene CH(C$H_3$)$_2$], 0.85 [d, $J$ = 6.8 Hz, 3 H, *p*-cymene CH(C$H_3$)$_2$] ppm. $^{13}$C NMR (75 MHz, $CDCl_3$): $\delta$ = 201.5 (N*C*N), 156.1 (*C*-OH), 138.6 (NHC aryl-C), 137.8 (NHC aryl-C), 136.8 (NHC aryl-C), 134.9 (NHC aryl-C), 129.5 (NHC aryl-C), 129.2 (NHC aryl-C), 127.5 (NHC aryl-C), 123.8 (NHC aryl-C), 120.0 (NHC aryl-C), 114.9 (NHC aryl-C), 112.6 (NHC aryl-C), 99.5 (br., *p*-cymene aryl-C), 97.6 (*p*-cymene aryl-C), 93.9 (br., *p*-cymene aryl-C), 91.9 (*p*-cymene aryl-C), 82.4 (br., *p*-cymene aryl-C), 78.0 (*p*-cymene aryl-C), 49.8 (N*C*$H_2$C$H_2$N), 47.4 (N*C*$H_2$C$H_2$N), 28.9 [*p*-cymene *C*H($CH_3$)$_2$], 22.1 (*C*$H_3$), 20.0 (*C*$H_3$), 19.8 (*C*$H_3$), 18.6 (*C*$H_3$), 17.3 (*C*$H_3$), 16.9 (*C*$H_3$) ppm. $C_{29}H_{35}ClN_2ORu$ (564.14): calcd. C 61.74, H 6.25, N 4.97; found C 61.48, H 6.12, N 4.56.

**NHC-Arene Complex 11:** Analogous to **8**, complex **11** was obtained as an orange solid in good yield (83%). Characterisation through $^1$H NMR spectroscopy was troublesome as the aromatic *p*-cymene protons and the backbone protons on the NHC appeared as very broad signals due to internal rotation of the ligands. $^1$H NMR (300 MHz, $CDCl_3$): $\delta$ = 7.19 (m, 1 H, aryl C*H*), 7.07 (br. s, 1 H, aryl C*H*), 7.03 (s, 1 H, aryl C*H*), 6.88 (m, 1 H, aryl C*H*), 6.58 (m, 2 H, aryl C*H*), 5.49–5.36 and 5.19 (br. signals, 4 H, *p*-cymene aryl-*H*), 4.26–3.92 (br. m, 4 H, NC$H_2$C$H_2$N), 2.69–0.88 (several signals) ppm. $^1$H NMR (300 MHz, $C_6D_6$): $\delta$ = 10.14 (br. s, 1 H, O*H*) ppm. $^{13}$C NMR (75 MHz, $CDCl_3$): $\delta$ = 202.2 (N*C*N), 151.2 (*C*-OH), 138.2 (NHC aryl-C), 136.5 (NHC aryl-C), 134.9 (NHC aryl-C), 131.1 (NHC aryl-C), 129.4 (NHC aryl-C), 128.2 (NHC aryl-C), 124.3 (NHC aryl-C), 119.4 (NHC aryl-C), 118.1 (NHC aryl-C), 116.9 (NHC aryl-C), 98.1 (br., *p*-cymene aryl-C), 95.0 (br., *p*-cymene aryl-C), 93.4 (br., *p*-cymene aryl-C), 80.9 (br., *p*-cymene aryl-C), 53.8 (br., N*C*$H_2$C$H_2$N), 29.3 [*p*-cymene *C*H($CH_3$)$_2$], 22.4 (*C*$H_3$), 21.7 (*C*$H_3$), 21.0 (*C*$H_3$), 20.4 (*C*$H_3$), 19.6 (*C*$H_3$), 19.1 (*C*$H_3$) ppm.

**Catalytic Reactions**

**ROMP of 2-Norbornene:** In a typical ROMP experiment (see Table 1), the catalyst (0.004248 mmol) in $CH_2Cl_2$ (0.5 mL) was transferred into a 15-mL vessel followed by the addition of 2-norbornene (1 g, 2500 equiv.) and toluene (10 mL). The reaction was then stirred at 85 °C for 3 h. To stop the polymerisation, a 2-ethyl vinyl ether/BHT(2,6-di-*tert*-butyl-4-methylphenol) solution in $CHCl_3$ was added. The reaction mixture was then poured into MeOH (50 mL) to precipitate the polymer. The polymer was isolated upon filtration and analysed gravimetrically by $^1$H NMR spectroscopy and GPC (gel permeation chromatography).

CCDC-652147 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

## Acknowledgments

The authors gratefully acknowledge the FWO-Flanders and the research Fund of Ghent University for generous financial support during the preparation of this manuscript. We wish to thank Olivier F. Grenelle and Dr. Marc G. Proot of Chevron Technology, Ghent, for elemental analyses and *dr* determination and Anthony Linden of the Institute of Organic Chemistry, University of Zürich, for collecting the crystallographic data set.

# 2-Arylimino-9-phenyl-1,10-phenanthrolinyl-iron, -cobalt and -nickel Complexes: Synthesis, Characterization and Ethylene Oligomerization Behavior

Suyun Jie,[a] Shu Zhang,[a] and Wen-Hua Sun*[a]

**Keywords:** Nitrogen ligands / Late transition metals / Iron / Ethylene / Oligomerization

A series of 2-imino-9-phenyl-1,10-phenanthrolines **1**–**6** has been prepared and investigated as new tridentate N3 ligands in coordination with metal chlorides. Their iron(II) (**1a**–**6a**), cobalt(II) (**1b**–**6b**), and nickel(II) (**1c**–**6c**) complexes have been synthesized and characterized by elemental and spectroscopic analysis in conjunction with single-crystal X-ray diffraction studies. Some of the iron complexes show good activities in the selective dimerization of ethylene upon treatment with MAO or MMAO, while the cobalt complexes show higher activities than their iron analogues and lead to the formation of $C_6$ and $C_8$ oligomers. The nickel complexes display high catalytic activities toward ethylene oligomerization in the presence of $Et_2AlCl$ and an auxiliary ligand ($PPh_3$).

## Introduction

Ethylene oligomerization is an important catalytic process for the production of linear α-olefins as basic chemicals.[1] The catalysts currently used in industrial processes include alkylaluminum compounds, a combination of alkylaluminum compounds and early transition metal complexes, nickel(II) complexes,[1a] and monoanionic [P,O] nickel-based catalysts (SHOP).[2] In the past decade, research on late transition metal complexes as catalysts for ethylene oligomerization and polymerization has attracted considerable attraction in both academic and industrial circles due to the possibility of their forming highly active and selective catalysts.[3–5] This was stimulated by the pioneering work by Brookhart's group,[6] who discovered that cationic α-diiminonickel complexes are effective catalysts for ethylene oligomerization and polymerization. Since this initial investigation of tetracoordinate nickel complexes, more attention has been paid recently to pentacoordinate complexes of nickel incorporating tridentate ligands such as N^N^O,[7] N^P^N,[8] P^N^N,[9] P^N^P,[9a] and N^N^N,[10–15] as well as their iron and cobalt analogues.

The discovery of highly active iron- and cobalt-based olefin polymerization catalysts was made possible by the design of bis(imino)pyridines as tridentate ligands by the Brookhart and Gibson groups,[16] who carried out detailed investigations of metal complexes bearing bis(imino)pyridine ligands by modifying the substituents on the aryl ring linked to the imino group and checking their influence on the catalytic activity and the resulting oligomerization or polymerization products.[4] Extensive research into alternative models of iron and cobalt complexes ligated with new types of tridentate $N_3$ ligands did not result in highly active precursors for ethylene oligomerization or polymerization.[17] Nevertheless, tridentate $N_3$ ligands are still of great interest for the preparation of late transition metal complexes as catalysts for ethylene oligomerization and polymerization[10–15,17–20] as the selective synthesis of short ethylene oligomers, particularly α-olefins, is of industrial importance.

The variation of catalyst models by designing new organic compounds that can be used as tridentate ligands has been targeted by our group for the production of highly active catalysts of iron and cobalt,[11,15,19,20] as well as nickel.[11–14] Some of these complexes have shown promising catalytic activities toward ethylene oligomerization and polymerization, such as highly active iron catalysts bearing 2-imino-1,10-phenanthrolines[19] and 2-(2-benzimidazolyl)-2-[1-(arylimino)ethyl]pyridines[15b] along with bimetallic iron complexes bearing 2-methyl-2,4-bis(6-iminopyridin-2-yl)-1*H*-1,5-benzodiazepines;[15a] their cobalt analogues also showed good activities.[15a,15b,20] Similarly to the bis(imino)pyridine catalytic systems,[4] we found that the above iron-based catalysts are generally more active than their cobalt analogues, although the exceptional cobalt complexes ligated by 2,9-bis(imino)-1,10-phenanthrolines showed better activity than their iron analogues.[11] Moreover, all the corresponding nickel complexes showed good catalytic activity for ethylene oligomerization,[11,12,14a] as did our more recent nickel complexes bearing 2-(benzimidazol-2-yl)-1,10-phenanthrolines.[13]

Along with the decisive influence of the ligands, especially the steric and electronic effects of substituents, on the

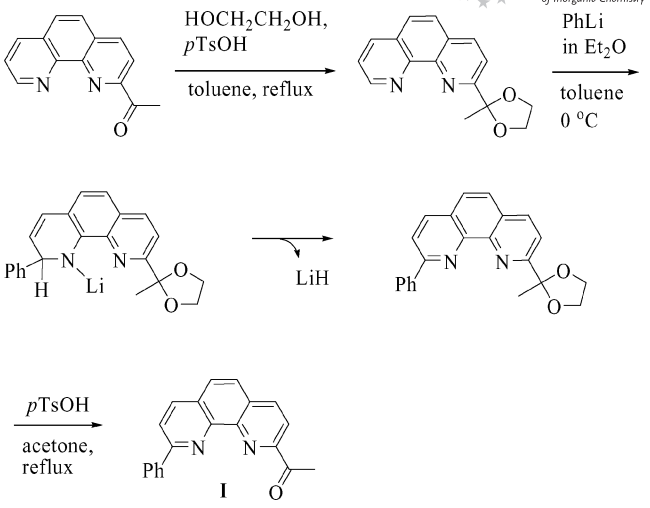
catalytic activities and products, the nature of the metal also greatly affects catalytic behavior. Metal complexes containing 2-imino-1,10-phenanthrolines generally show good to high catalytic activities for ethylene oligomerization and polymerization.[12,19,20] A high steric bulk of the ligands was recognized to be critical for a high catalytic activity of diiminonickel complexes for ethylene polymerization,[6] whereas, in comparison with 2-imino-1,10-phenanthrolinyl metal complexes,[12,19,20] the additional imino group in metal complexes bearing 2,9-diimino-1,10-phenanthrolines[11] has a negative effect as the additional imino group is assumed to coordinate to the active species, which results in a deactivated species. In order to check the effect of steric hindrance, 2-imino-9-phenyl-1,10-phenanthroline complexes have been targeted as precursors for ethylene oligomerization.

Herein we report the synthesis of 2-acetyl- and 2-benzoyl-9-phenyl-1,10-phenanthrolines and their subsequent transformation into 2-imino-9-phenyl-1,10-phenanthrolines for use as ligands. These compounds keep the same coordinative framework as 2-imino-1,10-phenanthrolines but with an additional phenyl group at the 9-position. Their late transition metal (Fe, Co, and Ni) complexes are synthesized and characterized and the catalytic properties of these complexes for ethylene oligomerization are evaluated under various reaction conditions. The effects of ligand environment and reaction conditions on the activity and the distribution of oligomers obtained are investigated systematically.

## Results and Discussion

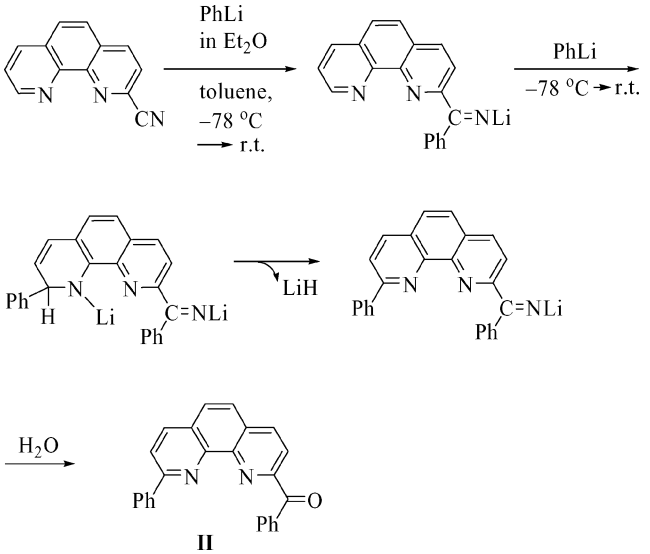
### Preparation of Ketones I and II

2-Cyano-1,10-phenanthroline and 2-acetyl-1,10-phenanthroline were prepared according to the literature procedures.[19a,21] 2-Acetyl-9-phenyl-1,10-phenanthroline (ketone I) was synthesized by attaching a phenyl group at the phenanthroline ring using 2-acetyl-1,10-phenanthroline as the starting material (Scheme 1). The carbonyl group of 2-acetyl-1,10-phenanthroline was first protected with ethylene glycol and the 2-(2-methyl-1,3-dioxolan-2-yl)-1,10-phenanthroline formed in this condensation reaction was purified on an alumina column.[22] A solution of 1.7 equivalents of phenyllithium in diethyl ether was added dropwise to a suspension of 2-(2-methyl-1,3-dioxolan-2-yl)-1,10-phenanthroline in toluene under nitrogen at low temperature (0 °C) and the reaction mixture was maintained for an additional 3 h at 0 °C.[23] This procedure gave 2-(2-methyl-1,3-dioxolan-2-yl)-9-phenyl-1,10-phenanthroline by elimination of lithium hydride.[24] 2-(2-Methyl-1,3-dioxolan-2-yl)-9-phenyl-1,10-phenanthroline was purified as a yellow oil on a silica column and then refluxed in acetone in the presence of *p*-toluenesulfonic acid to cleave the 1,3-dioxolane moiety. The desired product (2-acetyl-9-phenyl-1,10-phenanthroline) precipitated from the solution and was obtained by filtration as a pale-yellow solid.



Scheme 1. Synthesis of ketone I.

2-Benzoyl-9-phenyl-1,10-phenanthroline (ketone II) was prepared in a one-step reaction between 2-cyano-1,10-phenanthroline and three equivalents of phenyllithium (Scheme 2). Thus, a solution of phenyllithium in diethyl ether was added dropwise to a suspension of 2-cyano-1,10-phenanthroline in toluene at –78 °C, then the mixture was slowly warmed to room temperature and stirred overnight. The reaction proceeds by initial addition of phenyllithium to the nitrile group[25] followed by a Ziegler alkylation.[24] Subsequent hydrolysis gave the benzoyl-substituted product. The resultant mixture was extracted with dichloromethane and the organic phase was purified on a silica column. The desired compound (2-benzoyl-9-phenyl-1,10-phenanthroline) was obtained as a slightly yellow solid in acceptable yield.



Scheme 2. Synthesis of ketone II.

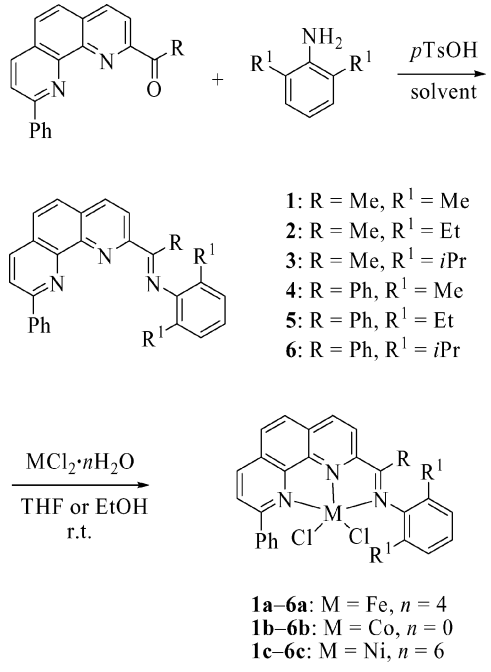
### Synthesis and Characterization of Ligands 1–6 and Complexes 1a–6a, 1b–6b, and 1c–6c

The 2-imino-9-phenyl-1,10-phenanthrolinyl ligands **1**–**6** were prepared by condensing ketones I or II with the corresponding substituted anilines in the presence of *p*-toluenesulfonic acid in toluene or tetraethyl silicate (Scheme 3). The ligands were obtained in high yield and were characterized by IR, $^1$H, and $^{13}$C NMR spectroscopy as well as elemental analysis. The iron complexes **1a**–**6a** were readily prepared by mixing the corresponding ligand with one equivalent of $FeCl_2{\cdot}4H_2O$ in thf at room temperature under nitrogen (Scheme 3). The resulting complexes precipitated from the reaction solution and were separated as air-stable green or brown solids. Similarly, the cobalt complexes **1b**–**6b** and nickel complexes **1c**–**6c** were synthesized by treating the corresponding ligand with one equivalent of $CoCl_2$ or $NiCl_2{\cdot}6H_2O$ in anhydrous ethanol at room temperature. The methyl ketimine cobalt complexes **1b**–**3b** were obtained as green powders, whereas the phenyl ketimine complexes **4b**–**6b** were red-brown. The corresponding nickel complexes **1c**–**6c** were obtained as orange or yellow powders. All complexes were well characterized by FT-IR spectroscopy and elemental analysis. A comparison of the IR spectra of the complexes and their corresponding ligands shows that the C=N stretching vibrations of the iron, cobalt, and nickel complexes are shifted to lower wavenumber and their peak intensities greatly reduced, thereby indicating a coordinative interaction between the imino nitrogen atom and the central metal. Some samples for elemental analysis were prepared as crystals, therefore the analytical results show the incorporation of solvent molecules. The structures of ligand **2**, iron complex **2a**, cobalt complexes **1b**, **4b**, and **6b**, and nickel complexes **1c** and **5c** in the solid state were confirmed by single-crystal X-ray diffraction analysis.



Scheme 3. Synthesis of ligands **1**–**6** and complexes **1a**–**6a**, **1b**–**6b**, and **1c**–**6c**.

### Crystal Structures

Single crystals of ligand **2** suitable for X-ray diffraction analysis were grown by recrystallization from a dichloromethane/hexane (1:5, v/v) solution. The molecular structure is shown in Figure 1. The imino nitrogen atom is disposed *trans* to the phenanthroline nitrogen atoms with a typical C=N double bond length of 1.270(2) Å. The phenyl ring on C1 is nearly coplanar with the plane of the phenanthroline moiety (dihedral angle: 6.2°), whereas the aryl ring on the imino nitrogen atom is approximately perpendicular to the plane of the phenanthroline moiety and the phenyl plane on C1 (dihedral angles: 92.1 and 89.6°, respectively).

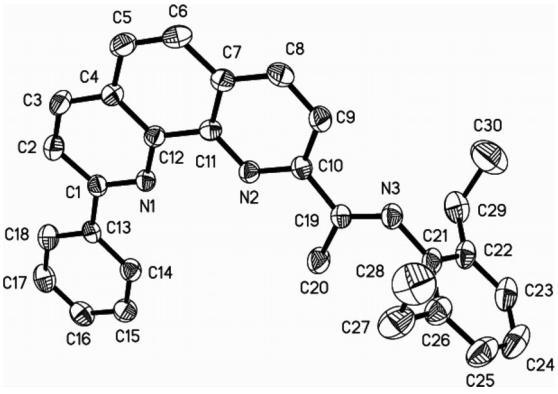


Figure 1. Molecular structure of ligand **2** with all hydrogen atoms omitted for clarity. Selected bond lengths [Å] and bond angles [°]: N1–C1 1.330(2), N1–C12 1.355(3), N2–C11 1.356(3), N2–C10 1.327(2), N3–C19 1.270(2), N3–C21 1.422(3); C19–N3–C21 121.62(2), N3–C19–C10 117.6(2), N3–C19–C20 125.0(2).

Single crystals of complex **2a** suitable for X-ray diffraction analysis were obtained by slow diffusion of diethyl ether into its methanol solution under nitrogen. The asymmetric unit of complex **2a** contains the halves of two independent molecules, as shown in Figure 2. The coordination geometry around the iron center can be described as a distorted trigonal bipyramid in which N2 of the phenanthroline group and two chlorides form the equatorial plane. The two independent molecules have slightly different bond lengths and bond angles, as shown in Table 1. The iron center deviates slightly (0.0469 Å) from the equatorial plane in both molecules, and the phenyl ring on C1 or C1A and the plane of the phenanthroline moiety make the same dihedral angle (53.5°), which is very different from that in the corresponding ligand **2** (6.2°). The plane of the phenanthroline moiety is nearly perpendicular to the equatorial plane [86.8° in (a) and 88.4° in (b)]. The dihedral angles between the phenyl ring on C1 or C1A and the equatorial plane are also the same (139.1°) for the two molecules, while the angles between the aryl ring on the imino nitrogen atom and the

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

equatorial plane are very different [56.8° in (a) and 78.9° in (b)]. The Fe–N bond in the equatorial plane in each molecule is clearly shorter than the two axial Fe–N bonds, and the axial Fe–N(phenanthroline) bond is about 0.1 Å longer than the Fe–N(imino) bond. The phenyl group on C1 results in a longer Fe–N1 bond length [av. 2.392(3) Å] than that of a related 2-acetyl-1,10-phenanthroline complex [2.271(3) Å].[19a] The two Fe–Cl bond lengths differ by about 0.1 Å. Although the two imino C=N bonds are slightly different [1.293(5) Å in (a) and 1.271(5) Å in (b)], they are both typical of an imino C=N double bond. The C=N bond length in molecule (b) is almost identical to that in ligand **2** [1.270(2) Å].

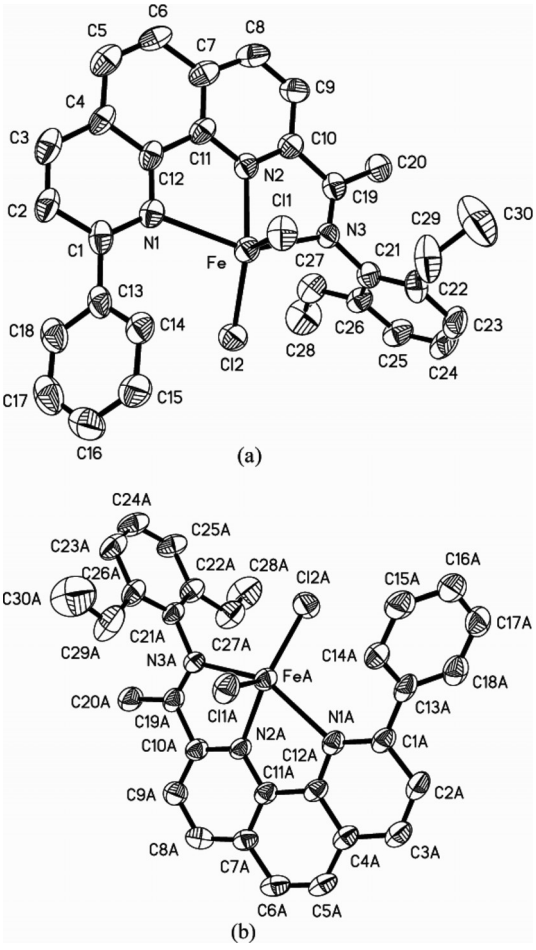

Figure 2. Molecular structure of complex **2a** showing the two crystallographically independent molecules of the asymmetric unit. Water molecules and all hydrogen atoms have been omitted for clarity.

Single crystals of cobalt complexes **1b**, **4b**, and **6b** were grown by slow diffusion of hexane into their solutions in dichloromethane. Their molecular structures are shown in Figures 3, 4, and 5, respectively, and selected bond lengths and angles are collected in Table 2. The coordination geometry around the cobalt center in these complexes can be described as a distorted trigonal bipyramid with N2 of the phenanthrolinyl group and two chlorides forming the equatorial plane.

Table 1. Selected bond lengths [Å] and angles [°] for complex **2a**.

| | | | |
|---|---|---|---|
| Fe–N1 | 2.391(3) | FeA–N1A | 2.393(3) |
| Fe–N2 | 2.101(3) | FeA–N2A | 2.104(3) |
| Fe–N3 | 2.298(3) | FeA–N3A | 2.283(3) |
| Fe–Cl1 | 2.3405(1) | FeA–Cl1A | 2.3456(1) |
| Fe–Cl2 | 2.2492(1) | FeA–Cl2A | 2.2469(1) |
| N3–C19 | 1.293(5) | N3A–C19A | 1.271(5) |
| N2–Fe–N1 | 73.77(1) | N2A–FeA–N1A | 73.18(1) |
| N2–Fe–N3 | 73.18(1) | N2A–FeA–N3A | 72.89(1) |
| N1–Fe–N3 | 145.86(1) | N1A–FeA–N3A | 144.89(1) |
| N1–Fe–Cl1 | 93.70(8) | N1A–FeA–Cl1A | 94.32(8) |
| N2–Fe–Cl1 | 98.23(9) | N2A–FeA–Cl1A | 98.71(9) |
| N3–Fe–Cl1 | 99.19(8) | N3A–FeA–Cl1A | 99.43(9) |
| N1–Fe–Cl2 | 104.73(9) | N1A–FeA–Cl2A | 105.71(9) |
| N2–Fe–Cl2 | 141.53(9) | N2A–FeA–Cl2A | 143.73(9) |
| N3–Fe–Cl2 | 95.87(9) | N3A–FeA–Cl2A | 96.35(9) |
| Cl1–Fe–Cl2 | 120.09(5) | Cl1A–FeA–Cl2A | 117.38(5) |

The cobalt atom in complex **1b** deviates slightly (–0.0517 Å) from the equatorial plane composed by N2, Cl1, and Cl2 and the axial Co–N bonds form an angle of 149.22(1)° (N1–Co–N3). The phenyl ring on C1 and the plane of the phenanthroline moiety form a dihedral angle of 41.0°, and the plane of the phenanthroline moiety is almost perpendicular to the equatorial plane (dihedral angle: 93.2°). The dihedral angles between the phenyl ring on C1 and the equatorial plane and the aryl ring on the imino nitrogen atom and the equatorial plane are 134.0° and 133.7°, respectively. The two axial Co–N distances [2.313(4) and 2.279(4) Å] are much longer than the Co–N bond [2.035(4) Å] in the equatorial plane and the two Co–Cl linkages differ by 0.06 Å. The imino N3–C19 bond length is 1.289(6) Å, which is typical of a C=N double bond.

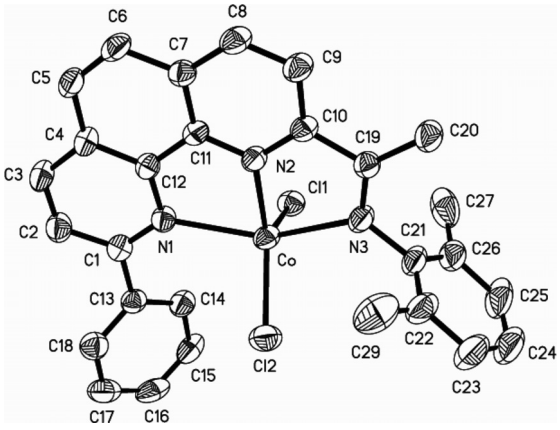

Figure 3. Molecular structure of complex **1b**. Water molecules and all hydrogen atoms have been omitted for clarity.

The central cobalt atom in the phenyl ketimine complex **4b** also deviates slightly (0.0196 Å) from the equatorial plane containing N2, Cl1, and Cl2. The bond lengths and angles around the cobalt center are very similar to those in **1b**, although the phenyl ring on C1 and the plane of the phenanthroline moiety make a dihedral angle (16.4°) that is very different from that in **1b** (41.0°). The phenyl ring on

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

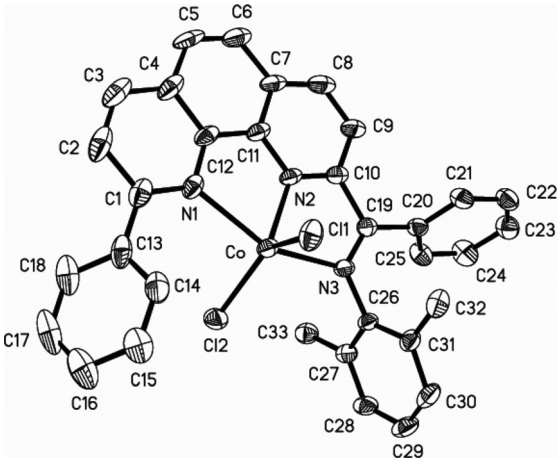

Figure 4. Molecular structure of complex **4b** showing one $CH_2Cl_2$ molecule. All hydrogen atoms have been omitted for clarity.

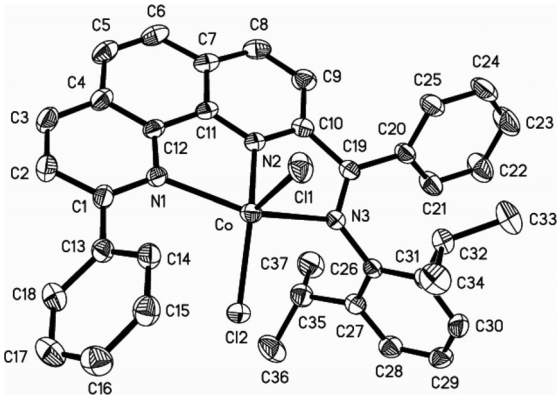

Figure 5. Molecular structure of complex **6b** showing one $CH_2Cl_2$ molecule. All hydrogen atoms have been omitted for clarity.

C1, the plane of the phenanthroline moiety, the phenyl ring on the imino carbon atom, and the aryl ring on the imino nitrogen atom are all approximately perpendicular to the equatorial plane, with dihedral angles of 80.1°, 88.9°, 91.5°, and 86.0°, respectively.

The central cobalt atom in the phenyl ketimine complex **6b**, which contains bulkier isopropyl groups at the *ortho* positions of the aryl ring at the imino nitrogen atom, deviates slightly more (0.1829 Å) from the equatorial plane containing N2, Cl1, and Cl2 than in the other complexes. This complex also has a smaller N2–Co–Cl1 bond angle [97.27(8)°] and larger N2–Co–Cl2 bond angle [140.69(8)°]. The two axial Co–N bonds also make a slightly smaller angle of 143.99(9)° (N1–Co–N3). In contrast to the other complexes, the phenyl ring on C1 is nearly coplanar to the plane of the phenanthroline moiety, with a dihedral angle of 3.3° that is much smaller than in other analogues and even smaller than in ligand **2** (6.2°). The dihedral angles between the phenyl ring on C1, the plane of the phenanthroline moiety, the phenyl ring on the imino carbon, and the aryl ring on the imino nitrogen and the equatorial plane [82.8°, 80.4°, 88.9°, and 89.2°, respectively] are similar to those in **4b**. The axial Co–N1(phenanthroline) bond in **6b** is 0.19 Å shorter than the Co–N3(imino) bond, which is very different from the situation in other cobalt analogues (about 0.04 Å in **1b** and **4b**). One possible reason for this is that the bulkier isopropyl groups at the *ortho* positions of the aryl ring bound to the imino nitrogen take up more space and lead to a shortening of the Co–N1 bond [2.180(2) Å] and a lengthening of the Co–N3 bond [2.372(2) Å]. This steric effect also leads to a shortening of the imino N3–C19 bond [1.255(4) Å].

Single crystals of nickel complexes **1c** and **5c** were obtained by layering hexane on their corresponding dichloromethane solutions. X-ray diffraction analysis revealed that they display a distorted trigonal bipyramidal geometry in which the central nickel atom is coordinated to three nitrogen atoms from the ligand and two halides. Similar to their iron and cobalt analogues, one nitrogen atom (N2) of the phenanthrolinyl group and two chlorides compose the equatorial plane; the imino nitrogen (N3) and another nitrogen (N1) of the phenanthrolinyl group occupy the two axial coordination sites. Their molecular structures are shown in Figures 6 and 7, respectively, and selected bond lengths and angles are collected in Table 2.

Table 2. Selected bond lengths [Å] and bond angles [°] in complexes **1b**, **1c**, **4b**, **5c**, and **6b**.

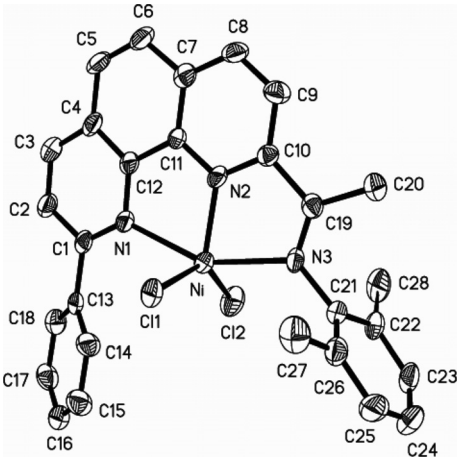

Figure 6. Molecular structure of complex **1c** showing one $CH_2Cl_2$ molecule. All hydrogen atoms have been omitted for clarity.

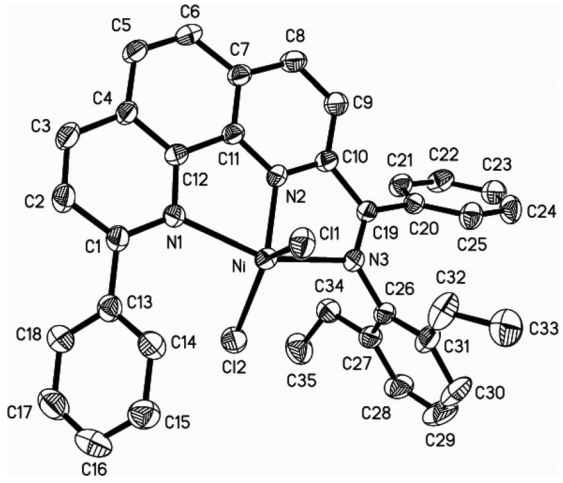

Figure 7. Molecular structure of complex **6b** showing two $CH_2Cl_2$ molecules. All hydrogen atoms have been omitted for clarity.

The central nickel atom in **1c** deviates by 0.0128 Å from the equatorial plane containing N2, Cl1, and Cl2 and the two axial Ni–Cl bonds make an axial angle (N1–Ni–N3) of 154.1(2)°. Both the equatorial plane and the plane of the phenyl group on the imino nitrogen are almost perpendicular to the plane of the phenanthroline moiety (dihedral angles of 84.8° and 87.8°, respectively). The plane of the pendant phenyl group on C1 makes a dihedral angle of 33.6° with the plane of the phenanthroline moiety and 51.2° with the equatorial plane. Similarly to a related phenanthrolinylnickel complex, the Ni–N bond in the equatorial plane is clearly shorter than the axial Ni–N bonds, although the presence of a phenyl group on C1 leads to an elongation of the Ni–N1 bond [2.300(7) Å vs. 2.157(3) Å];[12] the two Ni–Cl bond lengths are essentially identical. Despite showing typical character of a C=N double bond, the imino N3–C19 bond [1.275(9) Å] is slightly shorter than that in a related phenanthrolinylnickel complex [1.284(4) Å],[12] whereas much larger Cl1–Ni–Cl2 [137.71(1)°] and smaller N2–Ni–Cl1 [120.9(2)°] bond angles are observed after addition of a phenyl group at the 9-position of phenanthroline [110.62(4)° and 153.12(8)°, respectively, in the related nickel complex].[12]

Despite several similarities with **1c**, complex **5c** also has its own structural characteristics due to the presence of a phenyl group at the imino carbon instead of a methyl group. Thus, the central nickel atom deviates 0.0102 Å from the equatorial plane containing N2, Cl1, and Cl2, and the introduced phenyl group forms a dihedral angle of 5.7° with the plane of the phenanthroline moiety and is almost perpendicular to the equatorial plane (dihedral angle of 82.2°). The equatorial plane is still almost perpendicular to the plane of the phenanthroline moiety (dihedral angle of 87.5°), whereas the dihedral angle between the plane of the phenyl group on the imino nitrogen and the plane of the phenanthroline moiety decreases significantly to 7.2°. The plane of the pendant phenyl group on C1 makes a decreased dihedral angle of 8.0° with the plane of the phenanthroline moiety and an increased dihedral angle of 79.9° with the equatorial plane. All bond lengths and angles in **5c** are similar to those in **1c**.

## Ethylene Oligomerization

### *Ethylene Oligomerization with Iron Complexes 1a–6a*

The iron(II) complexes **1a**–**6a** were first investigated as ethylene oligomerization catalysts at 1 atm of ethylene pressure (Table 3), although the results were not satisfactory as almost no absorption of ethylene was observed with diethylaluminum chloride as co-catalyst. Activation with methylaluminoxane (MAO) gave a low catalytic activity for methyl-substituted complexes **1a** and **4a**, although ethyl-substituted complexes **2a** and **5a** were found to be less active and isopropyl-substituted complexes **3a** and **6a** completely inactive. Modified methylaluminoxane (MMAO) was found to be a more effective co-catalyst than MAO with a similar effect of the ligand environment on the catalytic activity. Thus, for complexes bearing the same substituents on the aryl ring of the imino nitrogen, phenyl ketimine (R = Ph) complexes **4a**–**6a** showed a relatively higher catalytic activity than the corresponding methyl ketimine (R = Me) complexes **1a**–**3a**. Complex **4a** exhibited the highest activity of $2.64 \times 10^5$ g mol$^{-1}$(Fe) h$^{-1}$, with 1-butene as the main product. Under the same reaction conditions, the variation of $R^1$ on the aryl ring of the imino nitrogen was found to have a strong influence on the catalytic activity. Thus, increasing the bulkiness of $R^1$ in both methyl and phenyl ketimine complexes caused the catalytic activity to decrease dramatically (methyl > ethyl > isopropyl), and in all cases essentially only dimerization was achieved, with a high selectivity for 1-butene.

The iron(II) complexes **1a**–**6a** were studied for ethylene oligomerization at 10 atm of ethylene pressure in the presence of MAO or MMAO; much higher catalytic activities were observed than those obtained at 1 atm (Table 3). With MAO as a co-catalyst the highest activity of $1.94 \times 10^6$ g mol$^{-1}$(Fe) h$^{-1}$ was obtained with complex **4a**. In general, however, under similar conditions, these complexes

[a] General conditions: cat.: 5 μmol; Al/Fe: 500; solvent (toluene): 30 mL for 1 atm and 100 mL for 10 atm; reaction time: 30 min. [b] Ethylene pressure. [c] Reaction temperature. [d] $10^4$ g mol$^{-1}$(Fe) h$^{-1}$. [e] Weight percentage determined by GC.

were found to be much less active than the corresponding 2-imino-1,10-phenanthrolinyliron complexes,[19] probably due to the presence of a phenyl group at the 9-position of the 1,10-phenanthroline ligand, which hinders the insertion of ethylene. MMAO was found to be more effective than MAO at 10 atm of ethylene pressure, and the methyl-substituted complexes **1a** [$2.69 \times 10^6$ g mol$^{-1}$(Fe) h$^{-1}$] and **4a** [$2.11 \times 10^6$ g mol$^{-1}$(Fe) h$^{-1}$] displayed the highest activity. The isopropyl-substituted complexes **3a** and **6a** always showed lower catalytic activity, probably because the bulkier isopropyl groups at the *ortho* positions of the aryl ring at the imino nitrogen affect the active species by preventing the coordination of an ethylene molecule at the metal center. A similar trend to that obtained at 1 atm as regards the effect of ligand environment on the catalytic activities and catalytic products was obtained for both the MAO and MMAO catalytic systems.

### *Ethylene Oligomerization with Cobalt Complexes 1b–6b*

Complex **5b** was studied as a model for ethylene oligomerization under varying conditions at 1 atm of ethylene pressure (Table 4). No catalytic activity was observed with diethylaluminum chloride (Al/Co = 100 or 200) as co-catalyst at 20 °C, whereas in the presence of MAO or MMAO (Al/Co = 500) the catalytic activity increased remarkable and the products mainly consisted of butene and hexene, with a high selectivity for 1-butene (>96%). The catalytic system **5b**/MAO showed a higher activity than **5b**/MMAO, although both gave a similar distribution of oligomers and a similar selectivity for 1-butene (entries 1 and 4, Table 4). MAO was therefore chosen as a co-catalyst during the subsequent investigations at 1 and 10 atm of ethylene pressure. The **5b**/MAO system showed the lowest activity, with a butene content in the oligomeric products of more than 90%, at an Al/Co molar ratio of 100 (entry 2, Table 4). Increasing the Al/Co molar ratio in the range 200–2000 led to an increase in the activity to $6.42 \times 10^5$ g mol$^{-1}$(Co) h$^{-1}$ at a Al/Co molar ratio of 500 and then a gradual decrease. The distribution of oligomers and the selectivity for 1-butene hardly changed.

The reaction temperature was found to have a remarkable influence on the catalytic activity and the distribution of oligomers. The highest activity was achieved at 20 °C and a slightly lower activity was obtained, although with a higher amount of butene produced (91.0%), at lower temperature (0 °C; entry 8, Table 4). An elevated reaction temperature also resulted in a decrease of the catalytic activity and butene content; for instance, **5b**/MAO showed an activity of $8.74 \times 10^4$ g mol$^{-1}$(Co) h$^{-1}$ with a 72.5% butene content at 80 °C (entry 11, Table 4). No significant difference was observed between methyl- and ethyl-substituted complexes for both methyl and phenyl ketimine complexes. However, the isopropyl-substituted complexes **3b** and **6b** displayed lower catalytic activities and gave a smaller amount of butene and higher amount of hexene than the corresponding methyl- or ethyl-substituted complexes. In contrast to bis(imino)pyridine,[4] 2-benzimidazolyl-6-iminopyridine,[15b] 2-quinoxalinyl-6-iminopyridine,[15c] and 2-imino-1,10-phenanthroline systems,[19,20] these cobalt complexes display much higher catalytic activities than their corresponding iron analogues under similar reaction conditions.

[a] General conditions: cat.: 5 μmol; co-cat.: MAO; solvent (toluene): 30 mL for 1 atm and 100 mL for 10 atm; reaction time: 30 min. [b] Ethylene pressure. [c] Reaction temperature. [d] $10^5$ g mol$^{-1}$(Co) h$^{-1}$. [e] Weight percentage determined by GC. [f] Co-cat.: MMAO.

When the ethylene pressure was increased from 1 to 10 atm the catalytic activity of each complex increased greatly, with a very high selectivity for 1-butene. Complex **5b** was found to have the highest activity [$7.33 \times 10^6$ g mol$^{-1}$(Co) h$^{-1}$; entry 21, Table 4]. For methyl ketimine complexes, methyl-substituted **1b** and ethyl-substituted **2b** showed comparable catalytic activities and a similar distribution of oligomers, whereas isopropyl-substituted **3b** showed a higher activity and gave a larger amount of hexene than **1b** or **2b**. A slightly higher amount of hexene was obtained for the corresponding phenyl ketimine complexes than with the methyl ketimine complexes. Complex **6b**, which contains bulkier isopropyl groups on the aryl ring of the imino nitrogen, was found to be slightly less active and produce a wider distribution of oligomers ($C_4$ to $C_{22}$, along with a small amount of polyethylene waxes) than **4b** or **5b** (entry 22, Table 4).

### *Ethylene Oligomerization with Nickel Complexes 1c–6c*

Complex **5c** was investigated for ethylene oligomerization in the presence of different co-catalysts at 1 atm of ethylene pressure. Unlike the nickel complexes ligated by other 1,10-phenanthroline derivatives,[11–13] almost no catalytic activity was observed with **5c** in the presence of MAO. When MMAO was used as a co-catalyst, however, slightly better activity was obtained and only butene was generated, with a high selectivity for 1-butene (entry 3, Table 5). However, $Et_2AlCl$ was found to be more effective as a co-catalyst for nickel complexes, although the selectivity for 1-butene was slightly lower. For example, at an Al/Ni molar ratio of 300, **5c**/$Et_2AlCl$ showed an activity of $1.43 \times 10^4$ g mol$^{-1}$(Ni) h$^{-1}$, with a selectivity of 78.5% for 1-butene, at 1 atm of ethylene pressure (entry 5, Table 5).

The addition of $PPh_3$ as an auxiliary ligand to nickel-based catalytic systems has been demonstrated to improve catalytic activity and prolong catalyst lifetime,[7a,12,26] although the mechanism is still not clear. However, in the presence of MAO, the addition of $PPh_3$ had no effect and the system still had no activity. For the catalytic system **5c**/MMAO, the addition of 10 equiv. of $PPh_3$ resulted in an increase in catalytic activity but a drastic decrease in the selectivity for 1-butene (entry 4, Table 5).

The effect of varying the amount of $PPh_3$ added on the catalytic activity and the selectivity for 1-butene was investigated with the catalytic system **5c**/$Et_2AlCl$ at 1 atm of ethylene pressure. Addition of two equivalents of $PPh_3$ improved the catalytic activity to $9.63 \times 10^4$ g mol$^{-1}$(Ni) h$^{-1}$, with a small amount of hexene generated, whereas the selectivity for 1-butene decreased from 78.5% to 27.1% (entry 6, Table 5). Increasing the amount of $PPh_3$ ($\leq$20) led to a further enhancement of catalytic activity and a further decrease of selectivity for 1-butene. The addition of 20 equivalents of $PPh_3$ gave the highest activity [$6.82 \times 10^5$ g mol$^{-1}$(Ni) h$^{-1}$] and the lowest selectivity (8.5%; entry 10, Table 5). Further increasing the amount of $PPh_3$ to 30 equivalents reduced the catalytic activity and increased the selectivity for 1-butene.

The effect of reaction temperature on the catalytic activity was also studied in the presence of 10 equivalents of $PPh_3$. When keeping the other conditions constant, the optimum catalytic activity was obtained at 20 °C; both increasing and decreasing the reaction temperature led to a lower catalytic activity and higher selectivity for 1-butene.

[a] General conditions: cat.: 5 μmol; co-cat.: $Et_2AlCl$; Al/Ni: 300; solvent (toluene): 30 mL for 1 atm and 100 mL for 10 atm. [b] $PPh_3$ was added as an auxiliary ligand. [c] Ethylene pressure. [d] Reaction temperature. [e] Reaction time. [f] $10^5\ g\,mol^{-1}(Ni)\,h^{-1}$. [g] Weight percentage determined by GC. [h] Co-cat.: MAO; Al/Ni: 500. [i] Co-cat.: MMAO; Al/Ni: 500.

In general, an induction time of 10–20 min is observed after the addition of $PPh_3$, and a lower temperature led to a longer induction time and catalyst lifetime. For instance, the catalytic activity of **5c** at 0 or 20 °C after 60 min was found to be higher than that after 30 min, although a lower selectivity for 1-butene was obtained with a slightly larger amount of hexene produced after 60 min, which indicates that the isomerization reaction of 1-butene to 2-butene takes place at the same time as the oligomerization reaction. Generally, phenyl ketimine complexes display slightly higher activities than methyl ketimine complexes bearing the same substituents on the aryl ring of the imino nitrogen. The catalytic properties of methyl ketimine complexes after 30 min were found to be not greatly affected by the substituents on the aryl ring of the imino nitrogen, and complexes **1c**–**3c** showed comparable catalytic activity and similar selectivity for 1-butene. However, when the reaction time was prolonged to 60 min a higher catalytic activity and slightly higher selectivity for 1-butene were achieved with ethyl-substituted **2c** than with methyl-substituted **1c** and isopropyl-substituted **3c**. For phenyl ketimine complexes, isopropyl-substituted **6c** showed the highest activity of $5.88\times10^5\ g\,mol^{-1}(Ni)\,h^{-1}$ after 30 min and methyl-substituted **4c** showed the highest activity of $4.71\times10^5\ g\,mol^{-1}(Ni)\,h^{-1}$ after 60 min (entry 23 and 24, Table 5).

The catalytic activity and selectivity for 1-butene of **5c** increased to $2.26\times10^5\ g\,mol^{-1}(Ni)\,h^{-1}$ and 97.1%, respectively (entry 26, Table 5) at 10 atm of ethylene pressure without $PPh_3$, whereas at 1 atm the catalytic activity and the selectivity for 1-butene did not change greatly when 10 equivalents of $PPh_3$ was introduced into the catalytic system (entry 27, Table 5), which means that both the $PPh_3$/Ni molar ratio and the concentration of $PPh_3$ in the reaction solution affect the catalytic properties. When the amount of $PPh_3$ was increased to 20 equivalents the catalytic activity of **5c** increased to $5.17\times10^6\ g\,mol^{-1}(Ni)\ h^{-1}$, with a lower selectivity for 1-butene (36.5%; entry 28, Table 5). Five other nickel complexes were therefore also investigated in the presence of 20 equivalents of $PPh_3$ at 10 atm of ethylene pressure. A higher catalytic activity and selectivity for 1-butene was obtained for each complex than at 1 atm, and the highest activity of $6.15\times10^6\ g\,mol^{-1}(Ni)\,h^{-1}$ was achieved with **2c**, with a selectivity of 50.2% for 1-butene.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

In general, the selectivity for 1-butene increases with increasing ethylene pressure, probably due to a competition between chain transfer and chain isomerization, and a higher ethylene concentration thus favors the formation of 1-butene due to rapid chain transfer rather than chain isomerization.[27]

## Conclusions

A series of iron, cobalt, and nickel complexes bearing 2-imino-9-phenyl-1,10-phenanthroline ligands have been synthesized, characterized, and evaluated as catalyst precursors in ethylene oligomerization. Some iron complexes show good catalytic activities, with high selectivity for ethylene oligomerization [**1a**/MMAO: $2.69 \times 10^6$ g mol$^{-1}$(Fe) h$^{-1}$], upon treatment with MAO or MMAO. Unexpectedly, in contrast to previous results with other tridentate $N_3$ catalytic systems, the cobalt complexes generally show much higher activities and broader oligomer distributions than the corresponding iron analogues. The ligand environment and the reaction parameters play an important role in influencing both the catalytic activity and the oligomer distributions for iron and cobalt complexes. The highest activity of up to $7.33 \times 10^6$ g mol$^{-1}$(Co) h$^{-1}$ for ethylene oligomerization has been obtained with the catalytic system **5b**/MAO at 10 atm of ethylene pressure. $Et_2AlCl$ is a more effective co-catalyst for nickel complexes, and the addition of $PPh_3$ significantly improves the catalytic activity and prolong the catalyst lifetime. The addition of 20 equiv. of $PPh_3$ leads to higher catalytic activities at 10 atm of ethylene pressure.

## Experimental Section

**General:** All manipulations of air- and moisture-sensitive compounds were carried out under an atmosphere of nitrogen using standard Schlenk techniques. Melting points were measured with a digital electrothermal apparatus without calibration. IR spectra were recorded with a Perkin–Elmer FT-IR 2000 spectrometer for KBr discs in the range 4000–400 cm$^{-1}$. $^1$H and $^{13}$C NMR spectra were recorded with a Bruker DMX-300 or DMX-400 instrument with TMS as the internal standard. Elemental analyses were performed with a Flash EA1112 microanalyzer. GC analyses were performed with a Varian CP-3800 gas chromatograph equipped with a flame ionization detector and a 30-m (0.2-mm i.d., 0.25-μm film thickness) CP-Sil 5 CB capillary column. The yield of oligomers was calculated by referencing to the mass of solvent on the basis of the prerequisite that the mass of each fraction is approximately proportional to its integrated area in the GC trace.

Toluene, diethyl ether and thf were refluxed over sodium-benzophenone and distilled under nitrogen prior to use. Diethylaluminum chloride was purchased from Acros Chemicals. Methylaluminoxane (MAO, 1.46 M in toluene) and modified methylaluminoxane (MMAO-3A, 7% aluminum in heptane solution) were purchased from Akzo Corp (USA). All other chemicals were obtained commercially and used without further purification unless otherwise stated.

**Synthesis of 2-Acetyl-9-phenyl-1,10-phenanthroline (I)**

**2-(2-Methyl-1,3-dioxolan-2-yl)-1,10-phenanthroline:** A mixture of 2-acetyl-1,10-phenanthroline (2.230 g, 10.0 mmol), glycol (3.254 g, 52.4 mmol) and *p*-toluenesulfonic acid (206 mg) was refluxed in toluene (100 mL) for 18 h until no further formation of water was observed in a Dean–Stark trap. The solvent was then removed under reduced pressure and the residue was eluted with petroleum ether/ethyl acetate (1:2, v/v) on an alumina column. The second eluting fraction was collected and concentrated to give a slightly yellow solid in 50.0% yield (1.333 g). M.p. 119–121 °C. FT-IR (KBr disc): $\tilde{\nu}$ = 3054, 2993, 2980, 2938, 2900, 1619, 1589, 1552, 1505, 1490, 1476, 1445, 1391, 1376, 1256, 1232, 1204, 1147, 1129, 1106, 1029, 1009, 953, 855, 789, 752, 675 cm$^{-1}$. $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 9.24 (d, $J$ = 4.4 Hz, 1 H, phen), 8.25 (d, $J$ = 8.4 Hz, 1 H, phen), 8.22 (d, $J$ = 8.4 Hz, 1 H, phen), 7.93 (d, $J$ = 8.4 Hz, 1 H, phen), 7.77 (s, 2 H, phen), 7.61 (dd, $J_1$ = 8.0 Hz, $J_2$ = 4.4 Hz, 1 H, phen), 4.18 (t, $J$ = 6.4 Hz, 2 H, $CH_2$), 4.01 (t, $J$ = 6.4 Hz, 2 H, $CH_2$), 1.98 (s, 3 H, $CH_3$) ppm. $^{13}$C NMR (100 MHz, $CDCl_3$): $\delta$ = 161.5, 150.5, 146.4, 145.8, 136.8, 136.0, 129.0, 128.1, 126.7, 126.3, 122.9, 119.5, 109.2, 65.2, 25.6 ppm. $C_{16}H_{14}N_2O_2$ (266.29): calcd. C 72.16, H 5.30, N 10.52; found C 72.18, H 5.23, N 11.00.

**2-Acetyl-9-phenyl-1,10-phenanthroline (I):** A phenyllithium solution was prepared by slowly adding a solution of bromobenzene (0.9 mL, 8.50 mmol) in diethyl ether (20 mL) to two equiv. of lithium (118 mg, 17.0 mmol) in diethyl ether (30 mL) at room temperature under nitrogen. The phenyllithium solution was then added dropwise to a suspension of 2-(2-methyl-1,3-dioxolan-2-yl)-1,10-phenanthroline (1.333 g, 5.00 mmol) in toluene (40 mL) at 0 °C and the initial yellow suspension turned dark brown. The resultant solution was stirred under nitrogen at 0 °C for an additional 3 h, then the reaction was quenched by slow addition of water (100 mL) and the mixture stirred. The yellow organic layer was separated and the aqueous layer was extracted several times with $CH_2Cl_2$. The organic phases were combined and dried with anhydrous sodium sulfate. After evaporation of the solvent the residue was purified on a silica column to give the pure product as a yellow oil. This oil was dissolved in 50 mL of acetone containing *p*-toluenesulfonic acid (170 mg) as a catalyst and refluxed for 15 h. The desired product was precipitated from the solution and collected by filtration as a pale-yellow solid in 47.5% yield (710 mg). M.p. 184–186 °C. FT-IR (KBr disc): $\tilde{\nu}$ = 3103, 3026, 2916, 1694, 1633, 1620, 1597, 1565, 1537, 1495, 1367, 1285, 1219, 1190, 1120, 1034, 1011, 888, 817, 766, 741, 678, 566 cm$^{-1}$. $^1$H NMR (300 MHz, $CDCl_3$): $\delta$ = 8.44 (d, $J$ = 7.2 Hz, 2 H, Ph), 8.34 (d, $J$ = 3.0 Hz, 2 H, phen), 8.30 (d, $J$ = 8.4 Hz, 1 H, phen), 8.17 (d, $J$ = 8.4 Hz, 1 H, phen), 7.88 (d, $J$ = 8.7 Hz, 1 H, phen), 7.78 (d, $J$ = 8.7 Hz, 1 H, phen), 7.59 (t, $J$ = 7.2 Hz, 2 H, Ph), 7.50 (t, $J$ = 7.2 Hz, 1 H, Ph), 3.14 (s, 3 H, $COCH_3$) ppm. $^{13}$C NMR (75 MHz, $CDCl_3$): $\delta$ = 200.3, 156.6, 152.3, 145.4, 144.8, 138.5, 136.5, 130.4, 129.3, 128.4, 128.1, 127.3, 127.0, 125.3, 119.7, 119.6, 25.2 ppm. $C_{20}H_{14}N_2O$ (298.34): calcd. C 80.52, H 4.73, N 9.39; found C 80.00, H 4.77, N 9.36.

**Synthesis of 2-Benzoyl-9-phenyl-1,10-phenanthroline (II):** A phenyllithium solution was prepared by slowly adding a solution of bromobenzene (3.2 mL, 30.5 mmol) in diethyl ether (20 mL) to two equiv. of lithium (439 mg, 63.2 mmol) in diethyl ether (30 mL) at room temperature under nitrogen. This phenyllithium solution was then added dropwise to a suspension of 2-cyano-1,10-phenanthroline (2.053 g, 10.0 mmol) in toluene (50 mL) at –78 °C and the mixture was slowly warmed to room temperature. After stirring for 12 h at room temperature, the reaction was quenched by slow addition of water (100 mL) and the mixture stirred. The red organic layer was separated and the aqueous layer was extracted several times with $CH_2Cl_2$. The organic phases were combined and dried with anhydrous sodium sulfate. After evaporation of the solvent the residue was purified on a silica column to give the pure product

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

as a yellow solid in 21.3% yield (1.245 g). M.p. 162–164 °C. FT-IR (KBr disc): $\tilde{\nu}$ = 3060, 3034, 1645, 1616, 1595, 1575, 1545, 1505, 1486, 1446, 1420, 1364, 1319, 1288, 1183, 1152, 1093, 1023, 944, 878, 865, 768, 716, 692 $cm^{-1}$. $^1H$ NMR (300 MHz, $CDCl_3$): $\delta$ = 8.93 (d, $J$ = 7.2 Hz, 2 H, Ph), 8.55–8.39 (m, 4 H), 8.30 (d, $J$ = 8.4 Hz, 1 H, phen), 8.16 (d, $J$ = 8.4 Hz, 1 H, phen), 7.89 (d, $J$ = 8.7 Hz, 1 H, phen), 7.81 (d, $J$ = 8.7 Hz, 1 H, phen), 7.72–7.62 (m, 3 H, Ph), 7.56–7.49 (m, 3 H, Ph) ppm. $^{13}C$ NMR (100 MHz, $CDCl_3$): $\delta$ = 191.4, 156.5, 153.4, 145.9, 144.6, 138.8, 136.7, 136.6, 132.7, 132.5, 129.8, 129.6, 128.6, 128.3, 127.8, 127.5, 127.3, 125.4, 122.6, 119.6 ppm. $C_{25}H_{16}N_2O$ (360.41): calcd. C 83.31, H 4.47, N 7.77; found C 82.94, H 4.45, N 7.73.

**Synthesis of Ligand 1:** A mixture of 2-acetyl-9-phenyl-1,10-phenanthroline (225 mg, 0.75 mmol), 2,6-dimethylaniline (184 mg, 1.50 mmol), and *p*-toluenesulfonic acid (80 mg) in toluene (20 mL) was refluxed for 24 h under $N_2$. The solvent was then evaporated under reduced pressure and the residue was eluted with petroleum ether/ethyl acetate (20:1, v/v) on an alumina column. The second fraction was collected and concentrated to give a yellow solid in 34.6% yield (105 mg). M.p. 190–192 °C. FT-IR (KBr disc): $\tilde{\nu}$ = 3041, 3018, 2914, 1635, 1605, 1590, 1546, 1506, 1485, 1467, 1362, 1293, 1204, 1118, 1091, 855, 761, 739, 687 $cm^{-1}$. $^1H$ NMR (300 MHz, $CDCl_3$): $\delta$ = 8.80 (d, $J$ = 8.4 Hz, 1 H, phen), 8.45 (d, $J$ = 7.5 Hz, 2 H, Ph), 8.34 (d, $J$ = 8.7 Hz, 2 H, phen), 8.18 (d, $J$ = 8.4 Hz, 1 H, phen), 7.85 (d, $J$ = 3.9 Hz, 2 H, phen), 7.56 (t, $J$ = 7.5 Hz, 2 H, Ph), 7.47 (t, $J$ = 7.5 Hz, 1 H, Ph), 7.11 (d, $J$ = 7.5 Hz, 2 H, Ar), 6.97 (t, $J$ = 7.5 Hz, 1 H, Ar), 2.62 (s, 3 H, $COCH_3$), 2.09 (s, 6 H, 2 Me) ppm. $^{13}C$ NMR (75 MHz, $CDCl_3$): $\delta$ = 168.0, 156.9, 155.8, 149.0, 146.0, 145.1, 139.2, 137.1, 136.5, 129.8, 129.6, 128.9, 127.9, 127.8, 127.5, 127.3, 126.1, 125.3, 123.1, 120.6, 119.9, 18.0, 16.7 ppm. $C_{28}H_{23}N_3$ (401.50): calcd. C 83.76, H 5.77, N 10.47; found C 83.69, H 5.76, N 10.40.

**Synthesis of Ligand 2:** Ligand **2** was prepared from 2-acetyl-9-phenyl-1,10-phenanthroline (446 mg, 1.50 mmol) and 2,6-diethylaniline (491 mg, 3.20 mmol) as a yellow solid in 44.2% yield (284 mg) in a similar manner to that described for ligand **1**. M.p. 181–183 °C. FT-IR (KBr disc): $\tilde{\nu}$ = 3060, 3037, 2960, 2929, 2868, 1639, 1608, 1589, 1546, 1507, 1486, 1452, 1418, 1369, 1296, 1258, 1194, 1119, 1099, 862, 828, 762, 740, 686 $cm^{-1}$. $^1H$ NMR (300 MHz, $CDCl_3$): $\delta$ = 8.80 (d, $J$ = 8.4 Hz, 1 H, phen), 8.45 (d, $J$ = 7.5 Hz, 2 H, Ph), 8.33 (d, $J$ = 8.4 Hz, 2 H, phen), 8.17 (d, $J$ = 8.4 Hz, 1 H, phen), 7.80 (d, $J$ = 3.9 Hz, 2 H, phen), 7.56 (t, $J$ = 7.5 Hz, 2 H, Ph), 7.47 (t, $J$ = 7.5 Hz, 1 H, Ph), 7.16 (d, $J$ = 7.2 Hz, 2 H, Ar), 7.07 (t, $J$ = 7.2 Hz, 1 H, Ar), 2.64 (s, 3 H, $COCH_3$), 2.42 (q, $J$ = 7.2 Hz, 4 H, 2 Et), 1.16 (t, $J$ = 7.2 Hz, 6 H, 2 Et) ppm. $^{13}C$ NMR (75 MHz, $CDCl_3$): $\delta$ = 167.7, 156.9, 155.9, 148.0, 146.0, 145.1, 139.2, 137.1, 136.5, 131.1, 129.8, 129.6, 128.9, 127.8, 127.5, 127.3, 126.1, 126.0, 123.4, 120.5, 119.8, 24.7, 17.0, 13.8 ppm. $C_{30}H_{27}N_3$ (429.56): calcd. C 83.88, H 6.34, N 9.78; found C 83.66, H 6.40, N 9.60.

**Synthesis of Ligand 3:** Ligand **3** was prepared from 2-acetyl-9-phenyl-1,10-phenanthroline (298 mg, 1.00 mmol) and 2,6-diisopropylaniline (448 mg, 2.50 mmol) as a yellow solid in 53.1% yield (243 mg) in a similar manner to that described for ligand **1**. M.p. 256–258 °C. FT-IR (KBr disc): $\tilde{\nu}$ = 3061, 2962, 2924, 2865, 1635, 1607, 1589, 1579, 1546, 1507, 1486, 1462, 1436, 1420, 1381, 1366, 1294, 1247, 1189, 1117, 1097, 860, 780, 761, 741, 685 $cm^{-1}$. $^1H$ NMR (400 MHz, $CDCl_3$): $\delta$ = 8.82 (d, $J$ = 8.4 Hz, 1 H, phen), 8.45 (d, $J$ = 7.6 Hz, 2 H, Ph), 8.33 (dd, $J_1$ = 8.4 Hz, $J_2$ = 4.7 Hz, 2 H, phen), 8.17 (d, $J$ = 8.4 Hz, 1 H, phen), 7.88 (d, $J$ = 4.0 Hz, 2 H, phen), 7.56 (t, $J$ = 7.6 Hz, 2 H, Ph), 7.47 (t, $J$ = 7.6 Hz, 1 H, Ph), 7.21 (d, $J$ = 7.6 Hz, 2 H, Ar), 7.13 (t, $J$ = 7.6 Hz, 1 H, Ar), 2.86 (sept, $J$ = 6.8 Hz, 2 H, 2 *i*Pr), 2.66 (s, 3 H, $COCH_3$), 1.19 (d, $J$ = 6.6 Hz, 6 H, *i*Pr), 1.17 (d, $J$ = 6.5 Hz, 6 H, *i*Pr) ppm. $^{13}C$ NMR (75 MHz, $CDCl_3$): $\delta$ = 167.7, 156.9, 155.8, 146.7, 146.0, 145.2, 139.2, 137.1, 136.5, 135.8, 129.9, 129.7, 129.0, 127.8, 127.5, 127.3, 126.1, 123.7, 123.1, 120.6, 119.9, 28.3, 23.3, 23.0, 17.3 ppm. $C_{32}H_{31}N_3$ (457.61): calcd. C 83.99, H 6.83, N 9.18; found C 84.00, H 6.84, N 8.98.

**Synthesis of Ligand 4:** 2-Benzoyl-9-phenyl-1,10-phenanthroline (760 mg, 2.10 mmol), 2,6-dimethylaniline (585 mg, 4.80 mmol), and *p*-toluenesulfonic acid (100 mg) were combined with tetraethyl silicate (5 mL) in a flask. The flask was equipped with a condenser and a Dean–Stark trap and the mixture was heated at about 130 °C for 36 h under $N_2$. Tetraethyl silicate was then removed under reduced pressure and the residue was eluted with petroleum ether/ethyl acetate (6:1, v/v) on an alumina column. The second fraction was collected and concentrated to give a yellow solid in 38.4% yield (376 mg). M.p. 142–144 °C. FT-IR (KBr disc): $\tilde{\nu}$ = 3055, 2943, 1616, 1589, 1577, 1544, 1505, 1484, 1441, 1368, 1319, 1290, 1207, 1088, 1024, 969, 858, 773, 765, 740, 716, 694 $cm^{-1}$. $^1H$ NMR (400 MHz, $CDCl_3$): $\delta$ = 8.87 (d, $J$ = 8.4 Hz, 1 H, phen), 8.37 (d, $J$ = 8.4 Hz, 1 H, phen), 8.26–8.24 (m, 3 H), 8.11 (d, $J$ = 8.4 Hz, 1 H, phen), 7.82 (s, 2 H, phen), 7.57 (d, $J$ = 8.0 Hz, 2 H, Ph), 7.46 (m, 4 H, Ph), 7.38 (t, $J$ = 7.2 Hz, 2 H, Ph), 6.96 (d, $J$ = 7.2 Hz, 2 H, Ar), 6.86 (t, $J$ = 7.2 Hz, 1 H, Ar), 2.12 (s, 6 H, 2 Me) ppm. $^{13}C$ NMR (100 MHz, $CDCl_3$): $\delta$ = 166.1, 155.9, 155.7, 148.2, 145.7, 144.7, 138.5, 136.3, 136.0, 135.4, 129.6, 129.2, 129.1, 128.9, 128.3, 127.9, 127.3, 127.0, 126.8, 126.7, 125.5, 125.2, 122.7, 121.7, 118.9, 18.2 ppm. $C_{33}H_{25}N_3$ (463.57): calcd. C 85.50, H 5.44, N 9.06; found C 85.14, H 5.47, N 8.94.

**Synthesis of Ligand 5:** Ligand **5** was prepared from 2-benzoyl-9-phenyl-1,10-phenanthroline (570 mg, 1.58 mmol) and 2,6-diethylaniline (498 mg, 3.27 mmol) as a yellow solid in 72.8% yield (556 mg) in a similar manner to that described for ligand **4**. M.p. 187–189 °C. FT-IR (KBr disc): $\tilde{\nu}$ = 3060, 3034, 2962, 2918, 1618, 1586, 1542, 1504, 1485, 1440, 1363, 1294, 1200, 1090, 965, 869, 763, 697 $cm^{-1}$. $^1H$ NMR (400 MHz, $CDCl_3$): $\delta$ = 8.85 (d, $J$ = 8.0 Hz, 1 H, phen), 8.37–8.22 (m, 4 H), 8.09 (d, $J$ = 8.0 Hz, 1 H, phen), 7.80 (s, 2 H, phen), 7.58 (s, 2 H, Ph), 7.45–7.36 (m, 6 H, Ph), 7.01–6.97 (m, 3 H, Ar), 2.61 (q, $J$ = 7.2 Hz, 2 H, Et), 2.34 (q, $J$ = 7.2 Hz, 2 H, Et), 1.16 (t, $J$ = 7.2 Hz, 6 H, 2 Et) ppm. $^{13}C$ NMR (100 MHz, $CDCl_3$): $\delta$ = 165.7, 156.2, 156.1, 147.6, 146.1, 145.1, 138.9, 136.7, 136.4, 135.4, 131.1, 130.3, 129.6, 129.2, 128.7, 128.5, 127.7, 127.5, 127.3, 127.2, 125.8, 125.5, 123.4, 122.1, 119.2, 24.5, 13.5 ppm. $C_{35}H_{29}N_3$ (491.62): calcd. C 85.51, H 5.95, N 8.55; found C 85.03, H 5.94, N 8.48.

**Synthesis of Ligand 6:** Ligand **6** was prepared from 2-benzoyl-9-phenyl-1,10-phenanthroline (394 mg, 1.09 mmol) and 2,6-diisopropylaniline (433 mg, 2.44 mmol) as a yellow solid in 74.0% yield (420 mg) in a similar manner to that described for ligand **4**. M.p. 170–171 °C. FT-IR (KBr disc): $\tilde{\nu}$ = 3063, 2958, 2860, 1611, 1588, 1544, 1506, 1487, 1463, 1430, 1358, 1291, 1194, 1091, 966, 858, 777, 757, 701 $cm^{-1}$. $^1H$ NMR (300 MHz, $CDCl_3$): $\delta$ = 8.84 (d, $J$ = 8.4 Hz, 1 H, phen), 8.38–8.24 (m, 4 H), 8.11 (d, $J$ = 8.4 Hz, 1 H, phen), 7.82 (s, 2 H, phen), 7.62 (m, 2 H, Ph), 7.49–7.39 (m, 6 H, Ph), 7.04 (m, 3 H, Ar), 3.00 (sept, $J$ = 6.8 Hz, 2 H, 2 *i*Pr), 1.19 (d, $J$ = 6.8 Hz, 6 H, *i*Pr), 0.97 (d, $J$ = 6.8 Hz, 6 H, *i*Pr) ppm. $^{13}C$ NMR (100 MHz, $CDCl_3$): $\delta$ = 164.9, 155.9, 145.7, 144.6, 138.5, 136.3, 136.0, 135.2, 134.5, 130.3, 129.1, 128.7, 128.4, 128.2, 128.1, 127.2, 127.1, 126.9, 126.7, 125.4, 123.2, 122.4, 121.8, 111.8, 28.1, 23.7, 21.6 ppm. $C_{37}H_{33}N_3$ (519.68): calcd. C 85.51, H 6.40, N 8.09; found C 84.91, H 6.36, N 7.84.

**Synthesis of Iron Complexes 1a–6a. General Procedure:** The ligand (0.20 mmol) and one equiv. of $FeCl_2{\cdot}4H_2O$ (0.20 mmol) were

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

placed in a Schlenk tube, which was purged three times with nitrogen and then charged with thf. The reaction mixture was then stirred at room temperature for 9 h. The resulting precipitate was filtered, washed with diethyl ether, and dried in vacuo. All the iron(II) complexes were isolated in high yield.

**Complex 1a:** Isolated as a green powder in 98.4% yield (104 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3059, 2953, 2918, 2867, 1615, 1590, 1555, 1504, 1491, 1468, 1451, 1435, 1374, 1299, 1205, 865, 792, 772, 745, 702 $cm^{-1}$. $C_{28}H_{23}Cl_2FeN_3 \cdot 1/2CH_2Cl_2$ (570.72): calcd. C 59.98, H 4.24, N 7.36; found C 59.61, H 4.34, N 7.28.

**Complex 2a:** Isolated as a green powder in 95.9% yield (107 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3063, 2966, 2929, 2872, 1617, 1584, 1558, 1504, 1490, 1442, 1374, 1289, 1243, 1205, 1193, 1152, 1141, 1060, 859, 786, 759, 744, 701 $cm^{-1}$. $C_{30}H_{27}Cl_2FeN_3$ (556.31): calcd. C 64.77, H 4.89, N 7.55; found C 64.26, H 4.59, N 7.50.

**Complex 3a:** Isolated as a green powder in 66.2% yield (78 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3062, 2969, 2926, 2865, 1611, 1590, 1557, 1501, 1490, 1463, 1440, 1374, 1330, 1286, 1247, 1185, 1152, 1138, 870, 786, 748, 701 $cm^{-1}$. $C_{32}H_{31}Cl_2FeN_3$ (584.36): calcd. C 65.77, H 5.35, N 7.19; found C 65.15, H 5.32, N 6.95.

**Complex 4a:** Isolated as a gray-green powder in 86.9% yield (103 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3056, 2922, 1620, 1588, 1549, 1489, 1445, 1368, 1300, 1212, 1155, 1001, 863, 774, 744, 703 $cm^{-1}$. $C_{33}H_{25}Cl_2FeN_3 \cdot H_2O$ (608.34): calcd. C 65.15, H 4.47, N 6.91; found C 65.12, H 4.11, N 6.85.

**Complex 5a:** Isolated as a brown powder in 79.8% yield (99 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3061, 2966, 2874, 1594, 1553, 1490, 1444, 1368, 1291, 1261, 1107, 1059, 1000, 868, 781, 702 $cm^{-1}$. $C_{35}H_{29}Cl_2FeN_3$ (618.38): calcd. C 67.98, H 4.73, N 6.80; found C 67.94, H 4.78, N 6.57.

**Complex 6a:** Isolated as a green powder in 86.6% yield (112 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3031, 2959, 2866, 1620, 1587, 1550, 1488, 1459, 1436, 1364, 1319, 1274, 1206, 995, 872, 850, 704 $cm^{-1}$. $C_{37}H_{33}Cl_2FeN_3$ (646.43): calcd. C 68.75, H 5.15, N 6.50; found C 68.42, H 5.23, N 6.59.

**Synthesis of Cobalt Complexes 1b–6b and Nickel Complexes 1c–6c. General Procedure:** The ligand (0.20 mmol) and one equiv. of $CoCl_2$ or $NiCl_2 \cdot 6H_2O$ (0.20 mmol) were placed in a Schlenk tube along with anhydrous ethanol. The reaction mixture was then stirred at room temperature for 9 h. The resulting precipitate was filtered, washed with diethyl ether, and dried in vacuo. All the complexes were isolated in high yield.

**Complex 1b:** Isolated as a green powder in 65.6% yield (70 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3063, 2945, 2914, 1619, 1585, 1557, 1504, 1490, 1451, 1437, 1374, 1290, 1256, 1206, 1142, 989, 919, 865, 791, 772, 745, 700, 653, 609 $cm^{-1}$. $C_{28}H_{23}Cl_2CoN_3 \cdot H_2O$ (549.36): calcd. C 61.22, H 4.59, N 7.65; found C 61.46, H 4.34, N 7.24.

**Complex 2b:** Isolated as a green powder in 80.3% yield (91 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3061, 2969, 2924, 2865, 1613, 1582, 1557, 1501, 1489, 1463, 1441, 1375, 1330, 1288, 1185, 1153, 869, 786, 749, 700 $cm^{-1}$. $C_{30}H_{27}Cl_2CoN_3$ (559.39): calcd. C 64.41, H 4.86, N 7.51; found C 64.25, H 4.92, N 7.27.

**Complex 3b:** Isolated as a green powder in 85.6% yield (103 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3450, 3062, 2964, 2932, 2875, 1618, 1585, 1558, 1504, 1490, 1441, 1375, 1290, 1193, 859, 787, 760, 745, 701 $cm^{-1}$. $C_{32}H_{31}Cl_2CoN_3$ (587.45): calcd. C 65.43, H 5.32, N 7.15; found C 64.48, H 5.55, N 6.61.

**Complex 4b:** Isolated as a red-brown powder in 80.2% yield (95 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3057, 2919, 1612, 1597, 1555, 1490, 1445, 1371, 1317, 1289, 1213, 999, 863, 774, 748, 721, 703 $cm^{-1}$. $C_{33}H_{25}Cl_2CoN_3 \cdot CH_2Cl_2$ (678.34): calcd. C 60.20, H 4.01, N 6.19; found C 60.25, H 4.02, N 6.28.

**Complex 5b:** Isolated as a red-brown powder in 77.6% yield (84 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3063, 2963, 2934, 2875, 1613, 1596, 1552, 1498, 1490, 1442, 1371, 1319, 1288, 1108, 995, 872, 782, 751, 720, 701 $cm^{-1}$. $C_{35}H_{29}Cl_2CoN_3 \cdot CH_2Cl_2$ (706.40): calcd. C 61.21, H 4.42, N 5.95; found C 60.68, H 4.28, N 5.63.

**Complex 6b:** Isolated as a red-brown powder in 78.4% yield (103 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3058, 3032, 2959, 2924, 2865, 1619, 1599, 1552, 1489, 1437, 1370, 1319, 1274, 1207, 1100, 995, 873, 850, 759, 718, 652 $cm^{-1}$. $C_{37}H_{33}Cl_2CoN_3 \cdot CH_2Cl_2$ (734.45): calcd. C 62.14, H 4.80, N 5.72; found C 62.17, H 4.82, N 5.54.

**Complex 1c:** Isolated as an orange powder in 89.3% yield (95 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3445, 3056, 1611, 1587, 1556, 1503, 1489, 1453, 1376, 1294, 1204, 1148, 862, 793, 773, 745, 702 $cm^{-1}$. $C_{28}H_{23}Cl_2N_3Ni \cdot 1/2CH_2Cl_2$ (573.57): calcd. C 59.68, H 4.22, N 7.33; found C 59.89, H 4.44, N 7.20.

**Complex 2c:** Isolated as an orange powder in 89.7% yield (100 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3442, 3062, 2958, 2871, 1616, 1584, 1559, 1502, 1489, 1442, 1377, 1302, 1292, 1192, 1060, 859, 787, 762, 744, 701 $cm^{-1}$. $C_{30}H_{27}Cl_2N_3Ni \cdot 1/2CH_2Cl_2$ (601.62): calcd. C 60.89, H 4.69, N 6.98; found C 60.46, H 4.96, N 6.67.

**Complex 3c:** Isolated as an orange powder in 76.5% yield (90 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3426, 3060, 2967, 2865, 1609, 1586, 1558, 1489, 1443, 1378, 1330, 1293, 1185, 1151, 869, 787, 761, 749, 702 $cm^{-1}$. $C_{32}H_{31}Cl_2N_3Ni \cdot CH_2Cl_2$ (672.14): calcd. C 58.97, H 4.95, N 6.25; found C 58.44, H 5.02, N 6.20.

**Complex 4c:** Isolated as a yellow powder in 96.0% yield (114 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3388, 1618, 1592, 1554, 1486, 1445, 1378, 1290, 1212, 1057, 1038, 1004, 868, 778, 754, 723, 703 $cm^{-1}$. $C_{33}H_{25}Cl_2N_3Ni \cdot H_2O$ (611.19): calcd. C 64.85, H 4.45, N 6.88; found C 65.09, H 4.16, N 6.82.

**Complex 5c:** Isolated as a orange powder in 90.6% yield (113 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3061, 2963, 1597, 1558, 1489, 1443, 1377, 1291, 1209, 1148, 1108, 1065, 1040, 1004, 867, 784, 706 $cm^{-1}$. $C_{35}H_{29}Cl_2N_3Ni \cdot 1/2CH_2Cl_2$ (663.69): calcd. C 64.24, H 4.56, N 6.33; found C 64.50, H 4.75, N 6.60.

**Complex 6c:** Isolated as an orange powder in 75.1% yield (98 mg). FT-IR (KBr disc): $\tilde{\nu}$ = 3440, 3057, 2962, 2866, 1621, 1595, 1554, 1490, 1439, 1377, 1322, 1293, 1207, 1151, 1101, 1024, 872, 784, 763, 707 $cm^{-1}$. $C_{37}H_{33}Cl_2N_3Ni \cdot 1/2CH_2Cl_2$ (691.75): calcd. C 65.11, H 4.95, N 6.07; found C 65.01, H 5.04, N 5.85.

**General Procedure for Ethylene Oligomerization at 1 atm of Ethylene Pressure:** A flame-dried, three-necked flask was loaded with the catalyst precursor and purged three times with nitrogen. Ethylene was then charged in the flask along with freshly distilled toluene and the mixture stirred for 10 min under 1 atm of ethylene pressure. The reaction temperature was controlled with a water bath and the required amount of co-catalyst was then injected with a syringe. The reaction mixture was stirred for the required time and then the reaction was quenched by addition of 5% aqueous hydrogen chloride. The contents and distributions of oligomers were determined by GC.

**General Procedure for Ethylene Oligomerization at 10 Atm of Ethylene Pressure:** A 250-mL stainless steel reactor equipped with a mechanical stirrer and a temperature controller was heated in vacuo for at least 2 h at above 80 °C, then cooled to the required reaction temperature under ethylene atmosphere and charged with toluene, the desired amount of co-catalyst, and a toluene solution of the

catalyst precursor; the total volume was 100 mL. The reactor was sealed and pressurized to 10 atm of ethylene pressure at the required reaction temperature, and the ethylene pressure was maintained with a feed of ethylene. After the required time the pressure was released. A small amount of the reaction solution was collected and the reaction quenched by addition of 5% aqueous hydrogen chloride. The organic layer was analyzed by GC to determine the composition and mass distribution of the oligomers obtained. Finally, the remaining reaction solution was quenched with 5% hydrochloric acid in ethanol.

**X-ray Crystallography:** Single-crystal X-ray diffraction studies for **1b**, **1c**, **2a**, and **5c** were carried out with a Bruker P4 diffractometer with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å) at 293(2) K. Intensity data for crystals of **2**, **4b** and **6b** were collected with a Bruker SMART 1000 CCD diffractometer with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). Cell parameters were obtained by global refinement of the positions of all collected reflections. Intensities were corrected for Lorentz and polarization effects and empirical absorption. The structures were solved by direct methods and refined by full-matrix least-squares on $F^2$. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were placed in calculated positions. Structure solution and refinement were performed with the SHELXL-97 package.[28] Crystallographic data and processing parameters for **1b**, **1c**, **2**, **2a**, **4b**, **5c**, and **6b** are summarized in Tables 6 and 7.

CCDC-650185 to -650191 contain the supplementary crystallographic data for this paper, which could be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# Orientation and Arrangement of Octaruthenium Supramolecules with Alkyl Chains on Graphite

**Dong-Lin Shieh,[a] Yi-Shiue Lin,[a] Kom-Bei Shiu,[a] and Jong-Liang Lin*[a]**

**Keywords:** Supramolecular chemistry / Scanning tunneling microscopy / Ruthenium

The self-assemblies of octaruthenium grid-type supramolecules, $\{[Ru_2(CO)_4(NH_2C_{16}H_{33})_2](\mu\text{-}O_2CCO_2)\}_4$, on highly oriented pyrolytic graphite (HOPG) in air and in 1-phenyloctane were studied by scanning tunneling microscopy (STM). The surface supramolecules are arranged into rows in which the metal cores are linearly packed and the alkyl chains are parallel to the surface. With the aid of theoretical calculations in the framework of density functional theory, the electronic origin of the tunneling in the measured STM images is discussed.

## Introduction

Nanoscience and nanotechnology have great potential for making a significant impact on our society. The design and fabrication of nanoscaled structures with functional properties have attracted considerable attention recently. A host of devices can be miniaturized by shrinking them in size (top-down approach). An alternative is a bottom-up approach based on assembly of building units at the molecular level. Self-organization and self-assembly are a well-established phenomenon and are critically important in living organisms as well as chemistry and material science.[1] Supramolecules formed through coordination chemistry exhibit versatile structures (square, triangle, cage, etc.) and ample metal-based or ligand-based functionality.[2,3] The incorporated electronic, magnetic, photochemical, photophysical, redox, and/or catalytic properties can lead to applications in molecular recognition, electrochemical sensing, information storage, catalysis, and so on. In addition, the well-defined cavities of the supramolecules create the possibilities of host–guest and inclusion chemistries.[4] As particle or device size diminishes, the ratio of surface area to volume increases and surface properties play a crucial role. Recently, ordered assemblies of supramolecules with transition-metal cyclic structures on surfaces were reported, such as grid-type Co, Zn, and Fe complexes on HOPG,[5] octaruthenium and tetraruthenium complexes on HOPG,[6] Pt complexes with shapes of rectangle, square, and cage on Au(111),[7] and square Pt complexes on chloride-covered Cu(100).[8] From a technological point of view, several key parameters need to be precisely controlled for these complexes, including physical and chemical properties, surface distribution, and molecular orientation of adsorbates.[4] A monolayer film structure is a combined result of the interactions between adsorbed molecules and the substrate and between adsorbed molecules themselves, which can be controlled by hydrogen bonding, dipole–dipole coupling, steric effects, and so on. $Cu^{II}$ salicyclic aldehyde complexes and aldimine derivative complexes show different adsorption layer lattices on HOPG,[9] that is, a film structure is modified by ligand substitution. Ligand substitution or only introduction of specific functional groups at given positions in the ligand moieties opens a pathway to control not only two-dimensional film structure but also the molecular orientation in the films.[5a] Recently, we reported that $\{[Ru_2(CO)_4(PMe_3)_2](\mu\text{-}O_2CCO_2)\}_4$, an octaruthenium supramolecule with a square shape (Figure 1, structure **1**), forms two kinds of two-dimensional, well-ordered assemblies on HOPG in air. One of the assemblies is composed of supramolecules containing Ru–Ru bonds perpendicular to the surface and the $PMe_3$ groups as outermost parts. In the other assembly, the supramolecules adopt an orientation with the Ru–Ru bonds parallel to the surface and the CO groups as outermost parts. The identification of the layer structure was based on the direct comparison of the dimensions of the octaruthenium supramolecule with the size of the bright lobes observed in the STM images. In the present study, we demonstrate the formation of a two-dimensional assembly of $\{[Ru_2(CO)_4(NH_2(CH_2)_{15}CH_3)_2](\mu\text{-}O_2CCO_2)\}_4$ on HOPG (Figure 1, structure **2**), in which the supramolecules are arranged in rows and the Ru–Ru bonds are parallel to the substrate surface. The possible tunneling origin for the observed images of the octaruthenium molecules is discussed with the aid of density functional theory calculations.

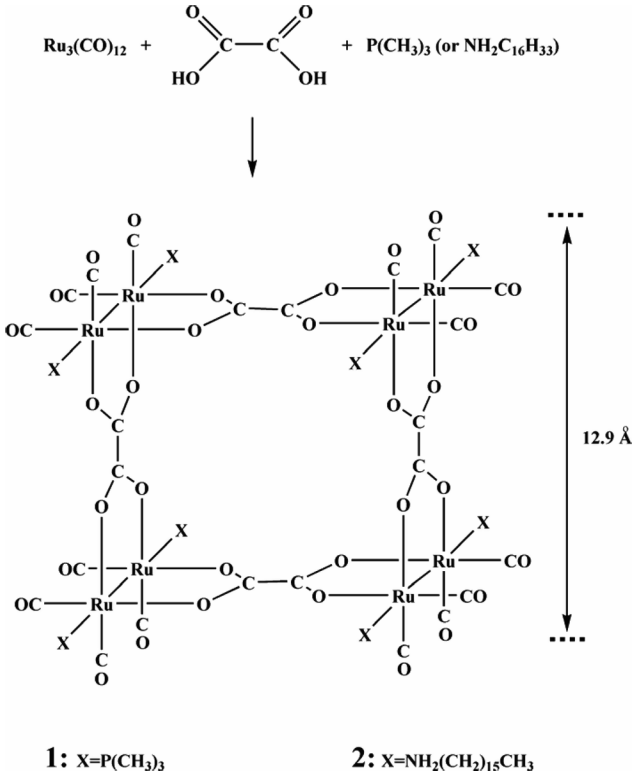

Figure 1. Formation of the grid-type octaruthenium complexes.

## Results and Discussion

Figure 2a presents a $15.0 \times 15.0$ nm$^2$ STM image of **2** on HOPG, assembled in $CH_2Cl_2$ and measured in air with a positive sample bias of 0.25 V in constant current mode (0.098 nA). This image shows a structure constituted by parallel rows. The width of each row is approximately 49.0 Å, with a linear bright region in the center area. The row width is close to the length (48 Å) of **2** calculated from one $CH_3$ end group to the other one on the opposite side across the metal cores on the basis of the theoretically optimized structure of **2** with zig–zag hydrocarbon chains. Figure 2b compares the *I–V* curve measured at the bright area in Figure 2a to the typical *I–V* curve of the pure HOPG plane. In the former case, the flat *I–V* feature about the zero bias voltage shows the presence of a bandgap. The measurements of the tunneling current at every bias were made three times and averaged to improve the signal-to-noise ratio. In some areas of **2**-covered HOPG, edges of islands formed by the ordered arrangement of the supramolecules can be observed. Figure 3a is a $600 \times 600$ nm$^2$ STM image, measured with a sample bias of –0.07 V and a tunneling current of 0.049 nA in air; it shows a step separating two terraces. On the basis of the tunneling image and the *I–V* spectrum measured around point A in the lower area (not shown), the dark terrace is attributed to a clean graphite surface. The row-like feature of Figure 2a is also observed in the high-resolution STM images taken in the bright terrace of Figure 3a, as shown in Figure S1 (Supporting Information). The line profile across the step (from point A to B) shows that the height difference between the two terraces is approximately 17 Å (Figure 3b), which is close to the height of the molecule, ca. 15.9 Å [sum of the oxygen nucleus-to-nucleus distance (12.9 Å, as indicated in Figure 1) and the van der Waals radii of two oxygen atoms (ca. 3 Å)]. These geometric similarities, the row width corresponding to the molecular length and the island height corresponding to the molecular height, indicate that the adsorbed supramolecules adopt an orientation with their long hydrocarbon chains and Ru–Ru bonds parallel to the surface. For an adsorbed molecule of **2** with this orientation, there are four coordinated CO molecules in contact with the surface.

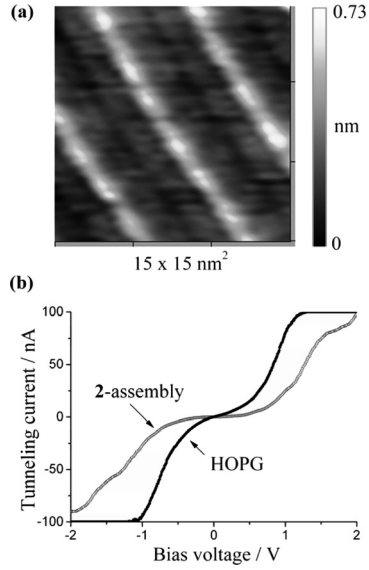

Figure 2. (a) STM image measured with a positive sample bias voltage of 0.25 V and a tunneling current of 0.098 nA in air of the assembly of **2** on HOPG. The width of the rows corresponds to the length of the molecule; (b) comparison of the *I–V* curves of clean and **2**-covered HOPG surfaces.

Because the formation of the layer structure of **2** on HOPG must depend on the interactions between **2** and the HOPG surface as well as on the interactions between molecules of **2**, a model compound, $\{[Ru_2(CO)_4(NH_3)(NH_2\text{-}C_8H_{17})](\mu\text{-}O_2CCO_2)\}_4$, on HOPG was calculated to address the bonding nature of **2**. In these calculations, the HOPG surface is represented by a sheet of carbon atoms fixed at the graphite lattice positions, with the edge carbon atoms coordinately saturated with H atoms. The total atom number (500 atoms) was confined by the software package in computation; therefore, only the model compound was studied instead of **2**. For the two adsorption systems of Figure 4a, b in which the adsorbed molecules have a 10° directional difference, the energy discrepancy is only 3 kcal mol$^{-1}$. This small difference in energy can be attributed to the weak van der Waals interaction between the molecule and the surface, which is not strongly dependent on the adsorption sites. The optimized 2.9 Å distance between the graphite surface and the O atom of the terminal CO (Figure 4a) is consistent with the sum of the van der Walls radii of C and O.

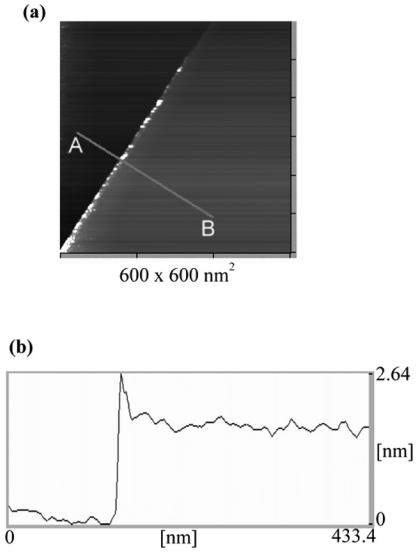

Figure 3. (a) A $600 \times 600$ nm$^2$ STM image measured in air with a sample bias voltage of –0.07 V and a tunneling current of 0.049 nA of a step separating a bright terrace representing a **2**-covered area and a dark terrace representing an uncovered area of HOPG; (b) the line profile from A to B shows that the height between the two terraces is ca. 17 Å.

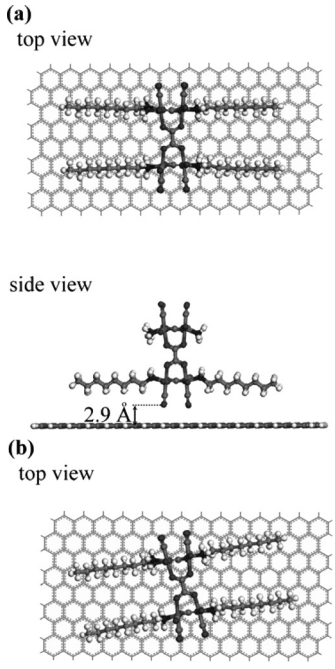

Figure 4. Optimized adsorption structures of a $\{[Ru_2(CO)_4(NH_3)(NH_2C_8H_{17})][\mu\text{-}O_2CCO_2]\}_4$ model compound in different directions (10° difference); structure (b) has an energy that is only 3 kcal mol$^{-1}$ higher.

To check the effect of the presence of solvent molecules on the adsorption structure and 2D array of **2** on HOPG, the assembly of **2** on HOPG was assembled and probed by STM in 1-phenyloctane. In a recent STM study of hexadehydrotribenzo[12]annulene derivatives (DBA) on HOPG, it was found that the structure of the DBA networks on HOPG is dramatically influenced by the presence of different solvent molecules.[10] The STM image of the ordered layer structure of **2** on HOPG measured in 1-phenyloctane with a +1.9 V sample bias voltage and a tunneling current of 0.049 nA is presented in Figure 5a. The molecules of **2** are packed into rows with a width of ca. 46.5 Å, similar to that observed in air. Figure 5b is a magnified image of the center region of Figure 5a, with a superimposed structure of **2** to show the matched length.

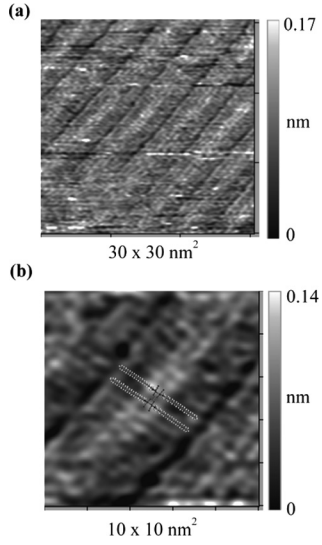

Figure 5. (a) A 30 nm × 30 nm STM image measured with a sample bias voltage of 1.9 V and a tunneling current of 0.049 nA in 1-phenyloctane of the assembly of **2** on HOPG; (b) magnified graph of the center region of (a) with a superimposed molecule of **2**.

To further address the origin of the tunneling, the molecular orbitals from the HOMO to HOMO-10 and from the LUMO to LUMO+9 of **2** were calculated in the framework of density functional theory (LDA-PWC). HOMO-*n* denotes the orbital below the HOMO by n energy levels; LUMO+*n* denotes the orbital above the LUMO by n energy levels. The wavefunctions from the HOMO to HOMO-3 of **2** and their relative energies are shown in Figure 6. The orbitals from the HOMO-4 to HOMO-10 are displayed in Figure S2 (Supporting Information). The orbitals from the HOMO to HOMO-3 mainly comprise Ru $4d_{z^2}$, N $2p_z$, and C $2p_z$ of the CO group and O $2p_z$ of the CO and $O_2CCO_2$ groups. The orbitals from the HOMO-4 to HOMO-7 contain the components of Ru 4d, N 2p, and O 2p of the CO and $O_2CCO_2$ groups. Ru 4d and O 2p of the CO and $O_2CCO_2$ groups contribute to the orbitals from HOMO-8 to HOMO-10. Figure 7 and Figure S3 (Supporting Information) show that the predominant contributions of the orbitals from the LUMO to LUMO+4 are C 2p and O 2p of the bridging $O_2CCO_2$ group. The orbitals from the LUMO+5 to LUMO+9 mainly consist of Ru 4d, C 2p, and O 2p of the terminal CO group. Our DFT calculations (LDA-PWC and GGA-PBE) show that the HOMO–LUMO gap of **2** is ca. 1.2 V. The self-assembled layer of **2** on HOPG in air was imaged at a small bias voltage of +0.25 V (Figure 1a). Different mechanisms were proposed for STM images of adsorbed molecules measured at low

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

bias voltages, in the gap between the HOMO and LUMO states, including work function modulation, resonant tunneling, and weak mixing of states of the molecule and substrate through molecule–substrate interaction.[11] In the case of the STM image of **2** assembled and measured in 1-phenyloctane, a +1.9 V sample bias was used. With an assigned HOMO–LUMO energy gap of 1.2 V and the assumption that the substrate Fermi level is located at the midpoint in the gap, the calculated energy levels from the LUMO to LUMO+9 are all below the Fermi level at a positive bias of 1.9 V, that is, these states become accessible for electron tunneling from HOPG to the molecules.

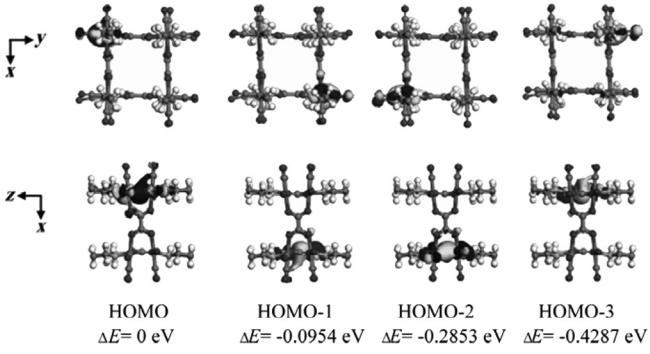

Figure 6. Individual molecular orbitals of **2** from the HOMO to HOMO-3 and their relative energies. $NH_2C_2H_5$ is used to replace $NH_2C_{16}H_{33}$ to save space.

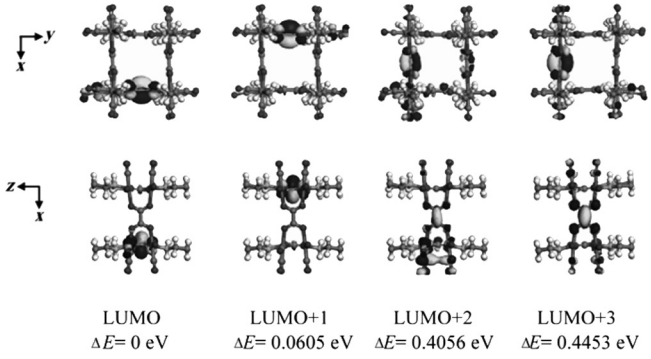

Figure 7. Individual molecular orbitals of **2** from the LUMO to LUMO+3 and their relative energies. $NH_2C_2H_5$ is used to replace $NH_2C_{16}H_{33}$ to save space.

## Conclusions

Grid-type octaruthenium complex **2** consisting of CO and $NH_2C_{16}H_{33}$ terminal ligands and a $O_2CCO_2$ bridging ligand was designed, synthesized, and studied with STM. Molecules of **2** on HOPG form an ordered assembly in which the molecules are arranged into rows, and they adopt an orientation with their Ru–Ru bonds and hydrocarbon chains parallel to the surface.

## Experimental Section

**Synthesis of $[Ru_2(CO)_4(NH_2C_{16}H_{33})_2](\mu\text{-}O_2CCO_2)_4$:** Freshly prepared $[Ru_3(CO)_{12}]$, oxalic acid·$2H_2O$, and THF were added in a pressure Schlenk tube. The mixture was heated to 120 °C while magnetically stirred for 6 h. To avoid the back-reaction, the gases evolved were drawn off from time to time. *n*-Hexadecylamine was then added. The solution was stirred for 2 h more, and then the solvents were removed under vacuum to afford a solid residue. Recrystallization from $CH_2Cl_2$/MeOH gave $[Ru_2(CO)_4(NH_2C_{16}H_{33})_2](\mu\text{-}O_2CCO_2)_4$. Yield: 83%. $^1H$ NMR (300 MHz, $CD_2Cl_2$): $\delta$ = 0.86 (t, $J$ = 6.4 Hz, 24 H, terminal $CH_3$), 1.54 (m, 16 H, $CH_2CH_3$), 2.32 (s, $NH_2$), 2.91 (t, $J$ = 7.1 Hz, 16 H, $CH_2NH_2$), 1.25 (m, 208 H, $104 \times CH_2$). IR ($CH_2Cl_2$): $\tilde{\nu}$ = 1591 (CO), 1979 (CO), 2030 (CO) $cm^{-1}$. $C_{152}H_{280}N_8O_{32}Ru_8$ (3540.47): calcd. C 51.6, H 8.0, N 3.2; found C 51.4, H 8.0, N 3.2.

**$[Ru_2(CO)_4(NH_2C_{16}H_{33})_2](\mu\text{-}O_2CCO_2)_4$ Film Preparation for STM Investigation:** The 2D layer structure of $[Ru_2(CO)_4(NH_2C_{16}H_{33})_2](\mu\text{-}O_2CCO_2)_4$ on HOPG was investigated in air and in 1-phenyloctane. The film formation procedures for these two STM studies were different. In the former case, a drop of $[Ru_2(CO)_4(NH_2C_{16}H_{33})_2](\mu\text{-}O_2CCO_2)_4$ in $CH_2Cl_2$ (0.01 M) was deposited on a freshly cleaved surface of HOPG (ZYB quality), which was placed in the middle of a glass container with a small amount of $CH_2Cl_2$ left on the bottom, and then the container was sealed immediately. After 6 h, the HOPG was taken out of the container and the $CH_2Cl_2$ was allowed to vaporize before STM images were recorded. It was found that **2** with the long alkyl chains $[-(CH_2)_{15}CH_3]$ needed much more time, relative to molecules of **1** reported previously, to pack into an ordered assembly by diffusion and adjustment of their relative positions in the interface of the solvent ($CH_2Cl_2$) and HOPG. In the case of **2** in 1-phenyloctane, a drop of 1-phenyloctane solution saturated with $[Ru_2(CO)_4(NH_2C_{16}H_{33})_2](\mu\text{-}O_2CCO_2)_4$ was placed on a freshly cleaved HOPG surface, which allowed the formation of an assembly of **2**. After 6 h, the surface was scanned by STM. Electrochemically etched W tips were used for the STM studies (Seiko Instruments, SPA 400) at constant current mode. All the STM images were collected with $256 \times 256$ data points.

**Molecular Orbital Calculations:** The optimized molecular structure as well as the orbitals and energies of $[Ru_2(CO)_4(NH_2C_{16}H_{33})_2](\mu\text{-}O_2CCO_2)_4$ were calculated in the framework of density functional theory by using the DMol$^3$ package, in which the Perdew–Wang local exchange and correlation function (LDA-PWC) and double-numerical basis set were employed. The calculations were spin-unrestricted and did not include a relativistic effect for the core electrons. In addition, another method, the generalized gradient approximation of Perdew, Burke, and Ernzerhof to the exchange and correlation functional (GGA-PBE), was also employed to calculate the supramolecular orbitals and their corresponding energies. A consistent HOMO–LUMO energy gap was obtained with both methods.

**Supporting Information** (see footnote on the first page of this article): Additional STM image and the HOMO- and LUMO-related orbitals of **2**.

## Acknowledgments

# Removal: "Ultra-Simple Synthesis of Ordered Mesoporous γ-Alumina: High Thermal Stability and Catalytic Activity"

**Le-Yue Li,[a] Quan Yuan,[b] Lei Liao,*[a] Chun-Hua Yan,[b] and Jun Chen[a]**

**Removal of Article from Wiley InterScience:** The article "Ultra-Simple Synthesis of Ordered Mesoporous γ-Alumina: High Thermal Stability and Catalytic Activity", published online on September 4, 2007 in Wiley InterScience (www.interscience.wiley.com) (DOI: 10.1002/ejic.200700645), has been removed.

The article was fraudulently submitted to the *European Journal of Inorganic Chemistry* without the approval of the authors named on the article, using false authorship details. The article was stolen in draft form from the computer network of the authors Chun-Hua Yan and Quan Yuan. No person at Wuhan University was involved in any way in the incident.

The Editor of the *European Journal of Inorganic Chemistry*, Dr. Karen Hindson, the authors and Wuhan University are satisfied with the severity of the punitive measures imposed upon the perpetrator of this fraud by the Ethics Commission of the College of Chemistry and Molecular Engineering of Peking University.

*The Authors/The Editor*

**The EUChemSoc Societies have taken the significant step into the future by merging their traditional journals, to form two leading chemistry journals, the *European Journal of Inorganic Chemistry* and the *European Journal of Organic Chemistry.* Three further EUChemSoc Societies (Austria, Czech Republic and Sweden) are Associates of the two journals.**

## COVER PICTURE

**The cover picture shows** the insertion of a $Pt^0$ complex fragment into the S−S bond of a 1,2,4-trithiolane 1-*S*-oxide. Reactions of $Pt^0$ complexes with small sulfur-containing heterocycles have become more and more popular in order to generate and stabilize reactive sulfur-containing species. The reaction presented leads to three- and four-membered platinacycles by ring contraction with expulsion of the reactive thiocarbonyl derivatives. The postulated mechanism for the fragmentation of 1,2,4-trithiolane 1-*S*-oxide, as well as the molecular structures, give a reasonable explanation for the observed selectivity. Details are discussed in the article by W. Weigand, G. Mloston et al. on p. 5627 ff. We thank Dr. Jaroslaw Romanski for decorating our Christmas tree (background) for this year and designing the cover picture.

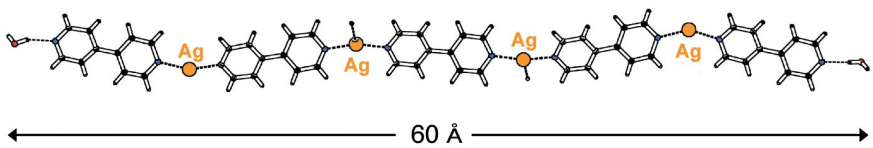
## SHORT COMMUNICATION

### Silver Coordination Oligomer

**Y. Wang, U. Englert* ..... 5623–5625**

The First Linear Coordination Oligomer Linked by 4,4′-Bipyridine

**Keywords:** Coordination polymers / Chain structures / Polycations / Oligomers / X-ray diffraction



Quite long, but no polymers yet! Coordination oligomers $[Ag_4(bipy)_5]^{4+}$ and $[Ag_2(bipy)_3]^{2+}$ were trapped in the same salt. A change in the counteranion was sufficient to induce polymerization.

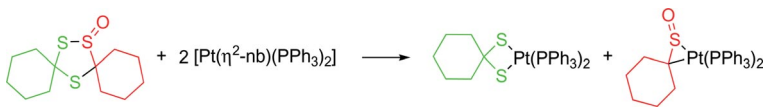
## FULL PAPERS

### Pt Chemistry

**H. Petzold, S. Bräutigam, H. Görls, W. Weigand,* J. Romanski, G. Mloston* ..... 5627–5632**

Oxidation of Spirocyclohexyl-1,2,4-trithiolane and Complexation Reaction with $[Pt(\eta^2\text{-nb})(PPh_3)_2]$

**Keywords:** Insertion reactions / 1,2,4-Trithiolanes / Platinum / S ligands / Thioketone complexes



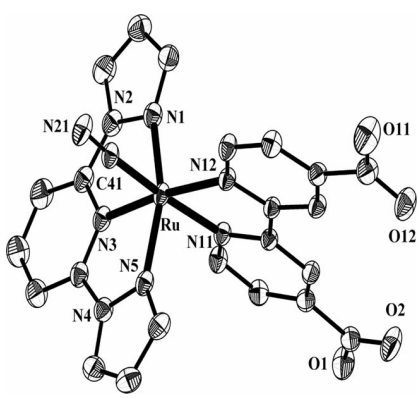
Insertion of a $Pt^0$ complex fragment into the S–S bond of a 1,2,4-trithiolane as well as into that of its 1-*S* and 4-*S*-oxide is presented. Subsequent ring contraction with expulsion of reactive thiocarbonyl derivatives leads to three- and four-membered platinacycles that include thiolato and sulfenato structures. The postulated mechanism and the molecular structures give a reasonable explanation for the observed selectivity.

### Heteroleptic Ruthenium(II) Complexes

**A. I. Philippopoulos,* A. Terzis, C. P. Raptopoulou, V. J. Catalano, P. Falaras ..... 5633–5644**

Synthesis, Characterization, and Sensitizing Properties of Heteroleptic $Ru^{II}$ Complexes Based on 2,6-Bis(1-pyrazolyl)pyridine and 2,2′-Bipyridine-4,4′-dicarboxylic Acid Ligands

**Keywords:** 2,6-Bis(1-pyrazolyl)pyridine / Heteroleptic $Ru^{II}$ complexes / Dye-sensitized solar cells / Ruthenium / Protonation



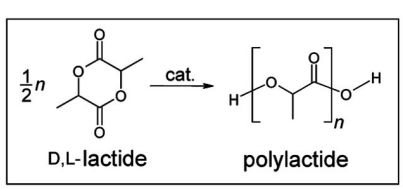
The synthesis and characterization of a series of novel heteroleptic ruthenium(II) complexes bearing the 2,6-bis(1-pyrazolyl)-pyridine (bpp) and 2,2′-bipyridine-4,4′-dicarboxylic acid ($dcbpyH_2$) ligands, as well as their performance as dye sensitizers in nanocrystalline solar cells for the conversion of visible light into electricity, is presented. These complexes efficiently sensitize nanostructured $TiO_2$ films and the resulting photoelectrodes incorporated in solid-state DSSCs show enhanced overall power conversion efficiency, which strongly depends on their molecular structure and their degree of protonation.

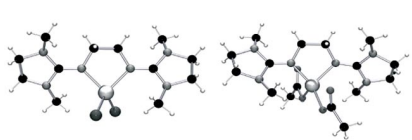
### (Guanidine)zinc Catalysts

**J. Börner, S. Herres-Pawlis,* U. Flörke, K. Huber ..... 5645–5651**

[Bis(guanidine)]zinc Complexes and Their Application in Lactide Polymerisation

**Keywords:** Guanidine / D,L-Lactide / N ligands / Ring-opening polymerization / Zinc





The first examples of aliphatic [bis(guanidine)]zinc complexes $[Zn(DMEG_2e)Cl_2]$, $[Zn(DMEG_2e)(CH_3COO)_2]$ and $[Zn(DMEG_2e)_2](CF_3SO_3)_2$ containing $N^1,N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine have been synthesised and fully characterised. These compounds are able to catalyse the polymerisation of D,L-lactide. PLAs with molecular weights ($M_w$) up to 59000 g/mol could be obtained.

## Ca-Mediated Styrene Polymerization

Increase of the steric bulk in the 2- and 7-positions of the fluorenyl ligands in several new organocalcium initiators led to a considerable improvement in the stereoselectivity for styrene polymerization. Syntheses, structures and polymerization results are discussed.

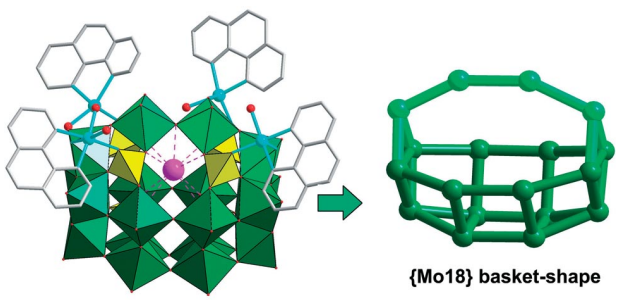
## Modified Polyoxoanions



A basket-like mixed-valent polyoxoanion $[Sr⊂P_6Mo_4^{V}Mo_{14}^{VI}O_{73}]^{10-}$ modified with $\{Cu(phen)(H_2O)_x\}$ ($x = 1-3$) fragments was hydrothermally synthesized and structurally characterized. The compound shows good electrocatalytic activity to reduce hydrogen peroxide.

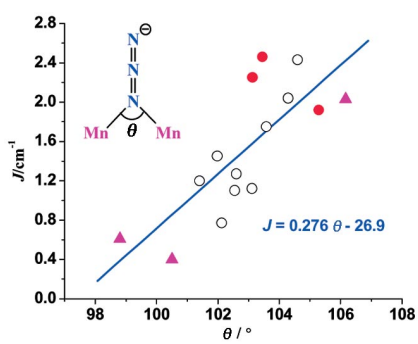
**K. Yu, Y.-G. Li,* B.-B. Zhou,* Z.-H. Su, Z.-F. Zhao, Y.-N. Zhang ..... 5662–5669**

A Basket-Like $[Sr⊂P_6Mo^{V}_4Mo^{VI}_{14}O_{73}]^{10-}$ Polyoxoanion Modified with $\{Cu(phen)(H_2O)_x\}$ ($x = 1-3$) Fragments: Synthesis, Structure, Magnetic, and Electrochemical Properties

**Keywords:** Polyoxometalate / Organic–inorganic hybrid / Basket-like / Electrocatalysis

## Magnetostructural Correlation

Three end-on azido dinuclear $Mn^{II}$ complexes based on tripyridyl ligands show intramolecular ferromagnetic superexchange. Clearer magnetostructural correlation for end-on azido-bridged $Mn^{II}$ complexes was obtained.

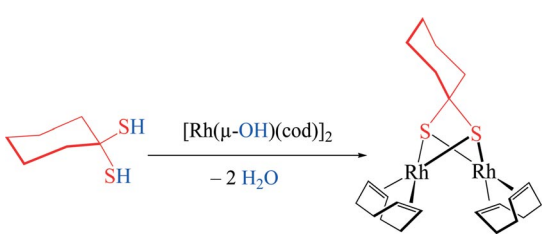


**M.-M. Yu, Z.-H. Ni, C.-C. Zhao, A.-L. Cui, H.-Z. Kou* ..... 5670–5676**

Synthesis and Magnetic Study of $\mu_{1,1}$-Azido-Bridged Dinuclear Manganese(II) Complexes Based on Tripyridyl Ligands

**Keywords:** Manganese / Dinuclear complexes / Crystal structures / Magnetic properties / Azido bridge

## Dimetallic Hydroformylation Catalysts



The *gem*-dithiolato-bridged dinuclear compound $[Rh_2(\mu\text{-}S_2Chxn)(cod)_2]$ was obtained in a straightforward manner from 1,1-dimercaptocyclohexane and $[Rh(\mu\text{-}OH)(cod)]_2$. This compound is an efficient catalyst precursor in the presence of P-donor ligands for the hydroformylation of oct-1-ene under mild conditions. The *trans*-dinuclear species $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PPh_3)_2]$ was isolated from the catalytic solutions

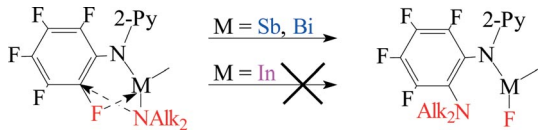
## Fluoride/Amide Exchange

**P. L. Shutov, S. S. Karlov,* K. Harms, M. V. Zabalov, J. Sundermeyer,* J. Lorberth, G. S. Zaitseva .... 5684–5692**

*ortho*-Directed Metathetical Fluoride/Amide Exchange in (Pentafluorophenyl)-amides

**Keywords:** Fluorinated ligands / Amides / Nucleophilic substitution / Density functional calculations



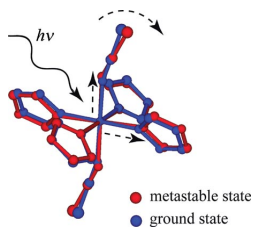
Metathetical fluoride/amide exchange has been examined in pentafluoro(2-pyridyl)-anilides of Sb, Bi, and In by synthetic and X-ray studies and density functional calculations. The tendency for this rearrangement increases with an increase of the covalent radius and decreases with an increase of the coordination number of the central atom.

## The Spin-Crossover Metastable State

**V. Legrand, S. Pillet, C. Carbonera, M. Souhassou, J.-F. Létard, P. Guionneau, C. Lecomte* .... 5693–5706**

Optical, Magnetic and Structural Properties of the Spin-Crossover Complex [Fe(btr)(NCS)]·HO in the Light-Induced and Thermally Quenched Metastable States

**Keywords:** Iron(II) / Photoswitching / Structural analysis / Photomagnetism / Spin crossover



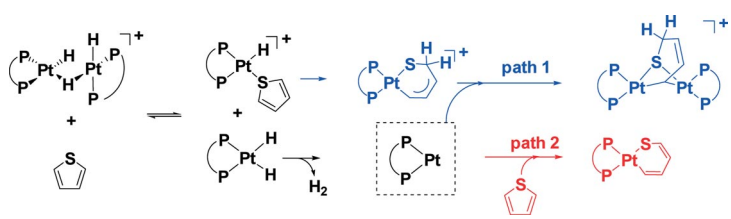
The light-induced and thermally induced structural reorganization of the spin-crossover complex $[Fe(btr)_2(NCS)_2]\cdot H_2O$ are discussed together with photomagnetic and optical reflectivity results.

## Hydrodesulfurization (HDS)

**A. Nova, F. Novio, P. González-Duarte*, A. Lledós,* R. Mas-Ballesté ..... 5707–5719**

C–S Bond Activation and Partial Hydrogenation of Thiophene by a Dinuclear Trihydride Platinum Complex

**Keywords:** C–S activation / Desulfurization / Thiophene / Hydride ligands / Platinum / Reaction mechanisms



Hydrodesulfurization reactions with transition metals: the reaction of $[(dppp)_2Pt_2H_3]$-$ClO_4$ with thiophene achieves activation of the C–S bond. The corresponding mechanism has been interpreted on the basis of DFT calculations. The reactivity of the complexes obtained in this reaction has led to the characterization of new platinum species.

## Phase Transition in $Pt(bpy)Cl_2$

Luminescence of the red form of $Pt(bpy)Cl_2$ has been measured as a function of hydrostatic pressure. The band maximum is shifted by $-147\ cm^{-1}\,kbar^{-1}$. Strong discontinuities in the optical properties at 17.7 kbar were interpreted in terms of a crystallographic phase transition from the red to a denser yellow form of $Pt(bpy)Cl_2$. First-principles calculations based on density functional theory were used to study this transformation.

## Platinum(II) Complexes with O-Donors

Acidolysis of the complexes $[Pt(CH_3)(terpy)]Y$ (Y = $PF_6$, $CH_3SO_3$, $CF_3SO_3$, $ClO_4$, $BF_4$; terpy = 2,2′:6′,2′′-terpyridine) with $CH_3SO_3$ affords the corresponding methanesulfonato derivatives $[Pt(OSO_2CH_3)(terpy)]Y$. A mixture of the methanesulfonato and nitrato complexes is obtained when Y = $NO_3$, whereas the reaction of $[Pt(CH_3)(terpy)](CF_3SO_3)$ with triflic acid gives the aqua species $[Pt(terpy)(H_2O)](SO_3CF_3)_2$. The new hydroxido-bridged dimers $[Pt_2(\mu\text{-}OH)(terpy)_2](X)$ [X = $(ClO_4)_3$, $(PF_6)_2(CF_3SO_3)$] are isolated and their X-ray crystal structures determined.

## COVER PICTURE

**The cover picture shows** the insertion of a $Pt^0$ complex fragment into the S−S bond of a 1,2,4-trithiolane 1-*S*-oxide. Reactions of $Pt^0$ complexes with small sulfur-containing heterocycles have become more and more popular in order to generate and stabilize reactive sulfur-containing species. The reaction presented leads to three- and four-membered platinacycles by ring contraction with expulsion of the reactive thiocarbonyl derivatives. The postulated mechanism for the fragmentation of 1,2,4-trithiolane 1-*S*-oxide, as well as the molecular structures, give a reasonable explanation for the observed selectivity. Details are discussed in the article by W. Weigand, G. Mloston et al. on p. 5627 ff. We thank Dr. Jaroslaw Romanski for decorating our Christmas tree (background) for this year and designing the cover picture.

# The First Linear Coordination Oligomer Linked by 4,4′-Bipyridine

Yutian Wang[a] and Ulli Englert*[a]

**Keywords:** Coordination polymers / Chain structures / Polycations / Oligomers / X-ray diffraction

A unique coordination oligomer derived from bridging 4,4′-bipyridine (bipy) ligands was synthesized and characterized. Long linear $[Ag_4(bipy)_5]^{4+}$ tetracations, shorter $[Ag_2(bipy)_3]^{2+}$ dications and 4-aminobenzoate anions represent the major constituents. When silver nitrate was added to solutions of this salt, polymerization in high yield occurred.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2007)

## Introduction

The optical, catalytic or magnetic properties of coordination polymers make them candidates for a plethora of potential applications.[1] The broad interest in this subject is reflected in an increasing number of publications during the last decade.[2] Active research is devoted to the structural chemistry of metal-containing polymers: about 11% of the structurally characterized organometallic and coordination compounds are polymeric.[3,4] 4,4′-Bipyridine (bipy) plays an important role among the organic linkers between metal cations. The relevance of this ligand for the construction of coordination polymers was recently reviewed by Biradha et al.[5] We encountered single-crystal to single-crystal reactions in surprisingly dynamic coordination polymers involving 4,4′-bipyridine.[6,7] To date, about 800 metal-containing derivatives of this organic ligand have been studied by diffraction methods; a large majority of these compounds contain bridging bipyridine molecules, but structures with a terminal bipy connected to a single metal cation through only one of the N donors have also been described.[8] Chemists intuitively associate polymers with oligomers as obvious intermediates; to the best of our knowledge, no linear coordination oligomer based on 4,4′-bipyridine, that is, no complex of finite nuclearity containing more than two metal atoms linked by this ligand, has ever been structurally characterized.[9] In this contribution, we wish to report the synthesis and characterization of the first oligocation based on bridging and terminal 4,4′-bipy ligands.

## Results and Discussion

Silver mono- or dicarboxylates and difunctional N donor ligands such as ethylendiamine,[10–12] 4,4′-bipyridine[13–21] or 1,2-diaminocyclohexane[22,23] have been reported to form polycationic $[Ag(ligand)^+]_\infty$ chains that are potentially cross-linked through weaker interactions such as argentophilic contacts or long Ag–O bonds. In contrast to this predictable behaviour, the reaction between silver 4-aminobenzoate and 4,4′-bipyridine results in the unexpected and unprecedented formation of **1**, which is a rather complex solid. Single-crystal X-ray diffraction showed that

Supporting information for this article is available on the WWW under http://www.eurjic.org/ or from the author.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

its building blocks comprise a dication $[Ag_2(bipy)_3]^{2+}$, a tetracation $[Ag_4(bipy)_5]^{4+}$, 6 4-aminobenzoate anions and 16 water molecules (Scheme 1).

The two cationic residues in the asymmetric unit are represented in Figure 1a,b: Ag–N bonds lead to the expected almost linear coordination of the $Ag^I$ centres, and deviations due to additional considerably longer and weaker interactions between the silver centres and the aqua or carboxylato oxygen atoms are also apparent. Five of the $Ag^I$ centres interact with two O donor ligands, whereas the sixth $Ag^I$ centre interacts with only one O donor ligand; the distances of these interactions fall in the range between 2.45 and 2.69 Å. Among the 16 water molecules in the asymmetric unit of **1**, 4 play a special role. Not only do they coordinate to the silver cations, but they also form hydrogen-bonding bridges with the dangling ends of the oligocations; the uncoordinated N atoms of the terminal bipy ligands act as acceptors. The long $[Ag_4(bipy)_5]^{4+}$ cations are crosslinked by bridging carboxylato oxygen atoms from two anions (Figure 1c).

The crosslinked longer residues and the discrete shorter cationic residues in **1** extend along the crystallographic *c* direction with stacking distances of approximately 3.5 Å. Matching torsion angles between the aryl rings along both polymer chains ensure a largely coplanar arrangement along the stacking direction (Figure 2).

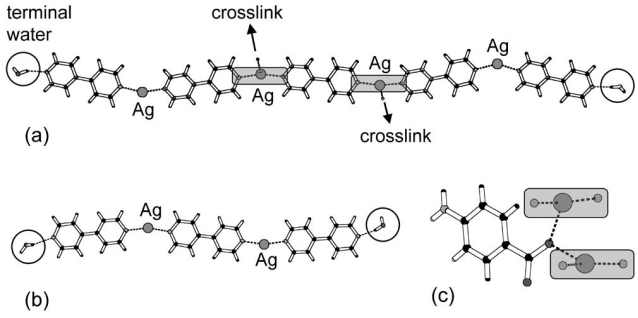

Figure 1. Tetracation $[Ag_4(bipy)_5]^{4+}$ (a) and dication $[Ag_2(bipy)_3]^{2+}$ (b) in **1**; the water molecules that are hydrogen bonded to the terminal pyridyl rings interact with metal centres in neighbouring residues through rather long coordinative bonds [Ag–O min 2.617(3), max 2.678(4) Å]; Ag···O interactions are not shown. (c) Geometry of a carboxylate crosslink between adjacent tetracations; the two symmetrically independent Ag···Ag distances are 3.2811(11) and 3.3773(11) Å.

Hydrogen bonding in **1** is limited by the number of H donors: The 16 water molecules and the 6 amino groups result in a total of 44 potential donor hydrogen atoms; the structure comprises a larger number of suitable classical acceptor sites, namely those associated with the 12 carboxylato and 16 water oxygen atoms, in addition to the 4 bipy N atoms. Of the 44 donor H atoms, 40 find an electronegative acceptor atom in reasonable geometry, and the remaining four, all of them aryl-bonded amino hydrogen atoms, point towards the centres of the aromatic rings in the adjacent anions. A detailed analysis of short interresidue contacts in **1** is provided in the Supporting Information.

As outlined above, 4 of the 16 water molecules in the asymmetric unit of **1** simultaneously participate in two different interactions with the ionic residues of the structure and both are hydrogen bonded and weakly metal coordinated. DSC and thermogravimetric studies show that the water molecules from **1** are released in two steps and in a 3:1 ratio upon heating. It is tempting to associate the second dehydration step with the loss of the more tightly bonded water molecules that terminate the oligocations.

## Conclusions

Compound **1** was obtained in high yields and should not simply be regarded as a singular novel structure. Solutions of the compound show the chemical reactivity expected for oligomers. The residues contributing to the formation of **1**, namely, 4-aminobenzoate, $Ag^I$ cations and the 4,4′-bipyridine ligand, in the additional presence of nitrate anions, take part in a different and less spectacular reaction described recently by Hong et al.[13] These authors obtained a one-dimensional coordination polymer of composition $\{[Ag(4,4'\text{-bipy})(H_2O)](aba)_{0.5}(NO_3)_{0.5}\cdot(H_2O)_{0.5}\}_\infty$ with infinite polycationic chains. The nature of the anions is decisive for the outcome of the reaction. When silver nitrate is added to a solution of oligomeric compound **1** in acetonitrile/water (Scheme 1), the above-mentioned coordination polymer precipitates almost quantitatively. The oligocations in **1** do not represent a dead end; rather, they are intermediates on the way to polymers that can be trapped under a favourable combination of counteranions.

## Experimental Section

Silver 4-aminobenzoate [Ag(aba)] was prepared from potassium benzoate and silver nitrate. Satisfactory microanalytical data were

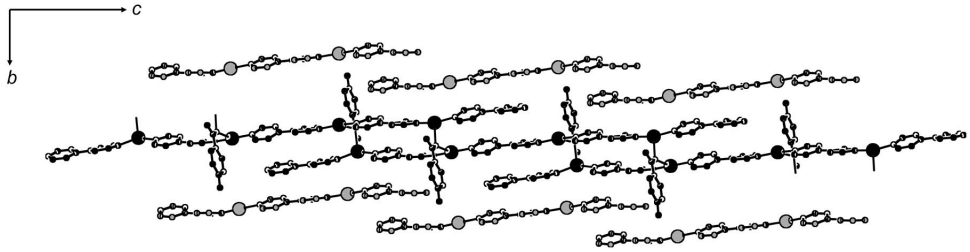

Figure 2. Arrangement of the anion-crosslinked tetracations (black) and the discrete dications (grey) in the crystal structure of **1**; the remaining four anions and the water molecules are omitted.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

obtained. The structure of this salt was determined by Amiraslanov et al.[24]

**1:** A solution of 4,4′-bipyridine (0.124 g, 0.8 mmol) in $CH_3CN$ (5 mL) was added to a solution of Ag(aba) (0.146 g, 0.6 mmol) in acetonitrile/water (1:1), and the mixture was stirred for 30 min at room temperature and then filtered. After 2 d of slow evaporation at room temperature, light-yellow crystals suitable for X-ray diffraction precipitated. Yield: 0.225 g [75%, based on Ag(aba)]. Compound **1** is stable when exposed to light. $C_{122}H_{132}Ag_6N_{22}O_{28}$ (3001.72): calcd. C 48.82, H 4.43, N 10.27; found C 48.68, H 4.46, N 10.20. $^1$H NMR (400 MHz; $CD_3CN/D_2O$, 1:1): $\delta$ = 6.72 (m, 6×2 H, 4-aminobenzoate), 7.68 (m, 6×2 H, 4-aminobenzoate), 7.81 (m, 8×4 H, 4,4′-bipyridine), 8.67 (m, 8×4 H, 4,4′-bipyridine) ppm. The spectrum confirms the composition of the bulk and the expected integration result of 24 H (6 anions) versus 64 H (8 bipyridine moieties).

Compound **1** was dehydrated in two steps, and the second step was close to decomposition. Around 100 °C, a weight loss of 7.8% (calculated for the loss of 12 $H_2O$ 7.2%) occurred and around 120 °C, a weight loss of 2.6% (calculated for the loss of 4 $H_2O$ 2.4%) occurred (Supporting Information).

The IR spectrum of **1** and that of the coordination polymer reported by Hong et al.[13] differ significantly in the region between 1420 and 1350 $cm^{-1}$. In contrast to the polymer, **1** does not contain $NO_3^-$ anions.

**Single-Crystal X-ray Structure Determination:** Data were collected with a Bruker Smart APEX CCD detector (Mo-$K_\alpha$ radiation, $\lambda$ = 0.71073 Å, graphite monochromator) with a D8 goniometer. Temperature was controlled with an Oxford Cryosystems Series 800 instrument. Intensities were integrated with SAINT[25] and corrected for absorption with SADABS.[26] Structures were solved by direct methods (SHELXS-97)[27] and refined on $F^2$ with SHELXL-97.[28]

**Crystal Data for 1:** Monoclinic space group $P2_1$, $a$ = 18.2356(11) Å, $b$ = 14.0626(8) Å, $c$ = 23.6767(14) Å, $\beta$ = 95.988(2)°, $V$ = 6038.5(6) Å$^3$, $Z$ = 2; $T$ = 130 K; refinement of 1604 parameters based on 29526 independent out of totally 70319 reflections converged at $R_1$ = 0.0506, $wR_2$ = 0.0994, $GOF$ = 1.000. In view of the inversion twinning [Flack parameter[29] 0.539(15)] encountered for the crystal documented here, intensity data on a second crystal were collected and a Flack parameter of 0.351(18) was obtained. CCDC-657268 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see footnote on the first page of this article): Crystal data and structure refinement, Ag coordination and intermolecular interactions, thermal analysis, polymerization and photographs of crystals.

# Oxidation of Spirocyclohexyl-1,2,4-trithiolane and Complexation Reaction with $[Pt(\eta^2\text{-nb})(PPh_3)_2]$

**Holm Petzold,[a] Silvio Bräutigam,[a] Helmar Görls,[a] Wolfgang Weigand,*[a] Jaroslaw Romanski,[b] and Grzegorz Mloston*[b]**

**Keywords:** Insertion reactions / 1,2,4-Trithiolanes / Platinum / S ligands / Thioketone complexes

Oxidation of spirocylcohexyl-1,2,4-trithiolane **1** yielded the 4-*S*- and 1-*S*-oxide, **2** and **3**, respectively. The complexation reactions of **1**–**3** with $[Pt(\eta^2\text{-nb})(PPh_3)_2]$ (**4**; nb = norbornene) have been studied. The formed dithiolato, thioketone, thiolatosulfenato and sulfine complexes **5**–**8** have been isolated and characterized by $^1$H-, $^{31}$P NMR and IR spectroscopy and by mass spectrometry. The mechanism of the reaction is discussed. The reaction proceeds by insertion of the $Pt^0$ complex fragment into the sulfur–sulfur bond and subsequent ring contraction by extrusion of a thioketone or sulfine. Comparison of the molecular structures of the oxidized complexes **7** and **8** with the nonoxidized complex **5** shows elongation of the sulfenato–platinum bond and elongation of the platinum–phosphorus bond in the corresponding *trans* position. The product formed suggests that, in this system, formation of thiolato–platinum bonds is energetically favoured to sulfenato–platinum bonds. The structures of **5**, **7** and **8** were established by X-ray crystallography.

## Introduction

1,2,4-Trithiolanes form a class of sulfur-rich five-membered heterocycles, which have attracted considerable attention in recent times. The parent compound as well as some 3,5-dialkyl-1,2,4-trithiolanes are naturally occurring substances.[1] On the other hand, 3,3,5,5-tetrasubstituted derivatives are easily formed as interception products of the reaction of intermediate thiocarbonyl *S*-sulfides (thiosulfines) with dipolarophilic thioketones.[2]

It is well known that the heating of these heterocycles in solution or in the gas phase (Flash Vacuum Pyrolysis, FVP) results in a cycloreversion reaction leading to thiosulfines (existing in an equilibrium with isomeric dithiiranes) and the corresponding thioketones.[3,4] In this way, 1,2,4-trithiolanes are used as a convenient source of in situ formed thiosulfines, which subsequently can be trapped by other dipolarophiles.[4] Very recently 1,2,4-trithiolanes have been used for syntheses of mimics for the active site of [Fe-only]-hydrogenase.[5,6] Along with the parent 1,2,4-trithiolane, there are also some oxidized species found in marine organisms.[7] In a recent investigation, the parent as well as the 3,3,5,5-tetramethyl-1,2,4-trithiolane were oxidized, and the diverse oxides were obtained and characterized. The study showed that the oxidation reactions with *m*-chloroperbenzoic acid (*m*-CPBA) result in the formation of a mixture of 1-*S*- and 4-*S*-oxides in comparable amounts.[8] Over the last years, reactions of cyclic disulfanes, thiosulfinates and thiosulfonates with $Pt^0$ have been described, which result in dithiolato, sulfenato thiolato, sulfinato thiolato, as well as thiosulfonato $Pt^{II}$ complexes. Except for the latter compound, all the compounds were formed by oxidative addition of $Pt^0$ complexes to the S–S(O)$_n$ moiety ($n$ = 0–2).[9–13] 1,2,4-Trithiolanes and their 1-*S*-oxides undergo reactions with $Pt^0$ complexes.[9,13]

Here we present a systematic investigation of the reactivity of the 1,2,4-trithiolane **1** and of its 4-*S*- and 1-*S*-oxide, **2** and **3**, respectively, with $[Pt(\eta^2\text{-nb})(PPh_3)_2]$ (**4**; nb = norbornene).

## Results and Discussion

The spirocyclohexyl-1,2,4-trithiolane **1** was oxidized by using *m*-CPBA. After separation by means of column chromatography, two main products were obtained as pure compounds (Scheme 1), along with some starting material and a mixture of two higher oxides.[14] The $^{13}$C NMR spectrum of the first eluted fraction shows 12 different signals. The signals at $\delta$ = 95.5 and 82.3 ppm are assigned to the quaternary C atoms C3 and C5. The second eluted fraction shows only six different signals, and for C3 and C5, only one signal at $\delta$ = 84.6 ppm is found. The elemental analysis and the found molecular peak in the mass spectra confirm

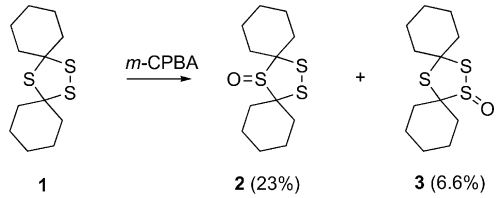
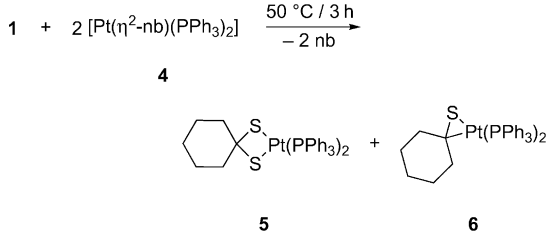
the formula $C_{12}H_{20}S_3O$; hence, the minor product is the 1-*S*-oxide **3** and the major product must be the 4-*S*-oxide **2**. The amount of the isolated 4-*S*-oxide **2** is nearly four times that of the 1-*S*-oxide **3**. Both products are crystalline; they are therefore more manageable than the tetramethyl derivatives.[8] The tendency to form the 4-*S*-oxide over the 1-*S*-oxide is well known for the unsubstituted 1,2,4-trithiolane and 3,3,5,5-tetramethyl-1,2,4-trithiolane.[7,8] In contrast, for the more bulkily substituted derivatives, such as tetraphenyl[13] and 3,5-di-*tert*-butyl-3,5-diphenyl derivatives,[15] exclusive oxidation at S1 and S2 is observed.



Scheme 1. Oxidation of spirocyclohexyl-1,2,4-trithiolane **1**.

Treatment of spirocyclohexyl-1,2,4-trithiolane **1** with 2 equiv. [Pt(η²-nb)($PPh_3$)$_2$] (**4**) in toluene at 50 °C yielded a 1:1 mixture of two complexes (Scheme 2) in the crude product according to the $^{31}$P NMR spectrum. This spectrum showed the existence of two spin systems, one $A_2$ spin system with a $^1J$(P,Pt) value of 2971 Hz and an AB spin system with a $^2J$(P,P) value of 16 Hz and $^1J$(P,Pt) values of 4600 Hz and 2838 Hz. The first spin system is typical for complexes of the type [Pt($PPh_3$)$_2$($S_2CR_2$)] and is assigned to the dithiolato complex **5**; fractional crystallization gave the pure complex **5** in 64% yield with respect to 2 equiv. **4**. The results of the X-ray analysis are shown in Figure 1. The complex has a distorted quadratic planar geometry with a small S–Pt–S angle of 75.54(2) °. The S–Pt bond lengths of 2.3123(7) and 2.3231(7) Å are slightly longer than the P–Pt bond lengths of 2.2874(7) and 2.2820(6) Å. The structure is comparable to those reported for the similar complexes.[10,16]



Scheme 2. Reaction of 1,2,4-trithiolane **1** with platinum complex **4**.

The second spin system observed in the $^{31}$P NMR spectrum is assigned to the thioketone complex **6**. An independent synthesis from cyclohexanonethione and [Pt(η²-nb)($PPh_3$)$_2$] yielded a sample whose identity was confirmed to be **6** by TLC and $^{31}$P NMR spectroscopy. The fragmentation of **1** found is similar to that reported for the reaction of bulkily substituted 1,2,4-trithiolanes with $Fe_2(CO)_9$.[5]

Similar treatment of the 4-*S*-oxide **2** with excess [Pt(η²-nb)($PPh_3$)$_2$] gave a 1:1 mixture of the thioketone complex **6**

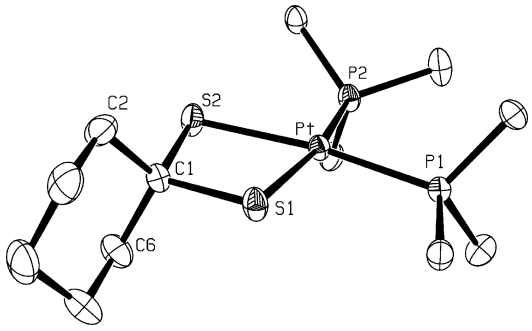


Figure 1. ORTEP[26] drawing of the molecular structure of the dithiolato complex **5** (for clarity, hydrogen atoms are omitted and the phenyl groups are represented only by their *ipso*-carbon atoms). Selected bond lengths (Å) and angles (°): Pt–P2 2.2874(7); Pt–P1 2.2820(6); Pt–S1 2.3123(7); Pt–S2 2.3231(7); S1–C1 1.847(3); S2–C1 1.836(3); P2–Pt–P1 99.89(2); S1–Pt–S2 75.54(2).

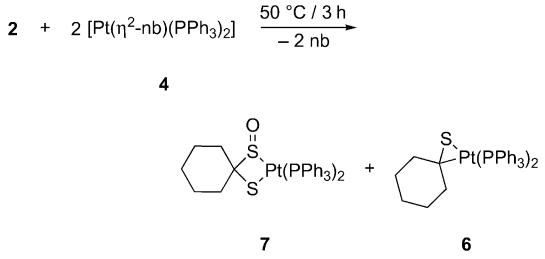
and a second complex **7** (Scheme 3). The pure complex **7** was isolated in 52% yield with respect to 2 equiv. **4** in a manner similar to that described for the dithiolato complex **5**. The $^{31}$P NMR spectrum of **7** shows an AB spin system with a $^2J$(P,P) value of 16 Hz and $^1J$(P,Pt) values of 3324 Hz and 2343 Hz. Elemental analysis and mass spectroscopy confirm the molecular formula of $C_{42}H_{40}OP_2PtS_2$. In the IR spectrum, a strong broad band is found at $\tilde{\nu}$ = 995 cm$^{-1}$, which is typical for sulfenato ligands bound to platinum(II).[11d,13] Finally, X-ray analysis unambiguously confirms the expected structure of the sulfenato thiolato complex **7**. The molecular structure of **7** is shown in Figure 2.



Scheme 3. Reaction of spirocyclohexyl-1,2,4-trithiolane 4-*S* oxide **2** with **4**.

The complex has a distorted sqare–planar geometry. The sulfur–platinum bond length (S1–Pt) is 2.3174(6) Å and is in the range of those found in the dithiolato complex **5**. A similar bond length relative to that in **5** is observed for the phosphorus–platinum bond P2–Pt [2.2944(6) Å] in the *trans* position. In contrast, the sulfur–platinum bond S2–Pt to the sulfenato ligand is slightly elongated by 0.01 Å. The higher *trans* influence of the sulfenato ligand results in an elongation the P1–Pt bond by approximately 0.04 Å. This observation is in a good agreement with the smaller value observed for the $^1J$(P,Pt) constant. The sulfur–oxygen bond in the sulfenato ligand [1.503(2) Å] is slightly longer than those reported for similar sterically crowded complexes.[12]

Complex **4** reacted with the 1-*S* oxide **3** at room temperature in a few minutes to yield a 1:1 mixture of the dithiolato complex **5** and a new product **8**, which shows an AB spin system with a $^2J$(P,P) value of 24 Hz and $^1J$(P,Pt) values of

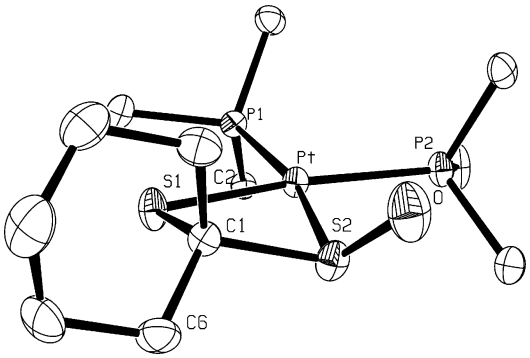

Figure 2. ORTEP[26] drawing of the molecular structure of the sulfenato thiolato complex **7** (for clarity, hydrogen atoms are omitted and the phenyl groups are represented only by their *ipso*-carbon atoms). Selected bond lengths (Å) and angles (°): Pt–P2 2.2944(6); Pt–P1 2.3193(6); Pt–S1 2.3174(6); Pt–S2 2.3336(6); S1–C1 1.837(2); S2–C1 1.858(2); S2–O 1.503(2); P2–Pt–P1 100.01(2); S1–Pt–S2 74.33(2).

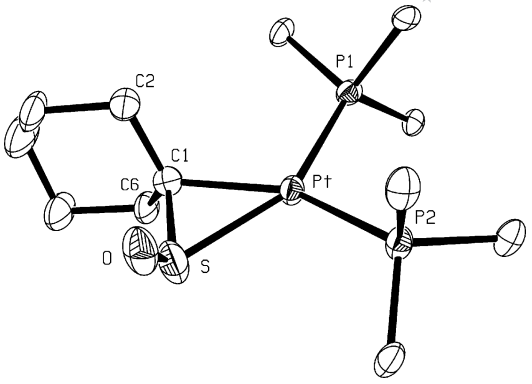

Figure 3. ORTEP[26] drawing of the molecular structure of the sulfine complex **8** [for clarity, hydrogen atoms and O1A are omitted and the phenyl groups are represented only by their *ipso*-carbon atoms]. Selected bond lengths (Å) and angles (°): Pt–P2 2.3038(16); Pt–P1 2.2867(16); Pt–S1 2.3338(18); Pt–C1 2.126(6); S1–C1 1.770(6); S1–O1 1.436(8); S1–O1A 1.321(13); P2–Pt–P1 105.29(6); S1–Pt–C1 46.48(17).

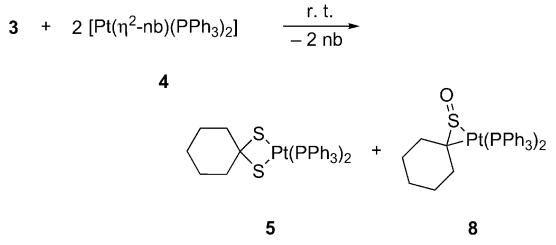
3817 Hz and 3075 Hz in the $^{31}P$ NMR spectrum (Scheme 4). In the mass spectrum, the molecular peak is found at $m/z$ = 850, and the elemental analysis confirms the molecular formula $C_{42}H_{40}OP_2PtS$. On the basis of these data, structure **8** can be assigned to the isolated complex. The result is in good agreement with that observed in the reaction between 3,3,5,5-tetraphenyl-1,2,4-trithiolane 1-*S*-oxide and $[Pt(\eta^2\text{-}C_2H_4)(PPh_3)_2]$.[13] Recrystallization from a thf/pentane mixture yielded crystals that were suitable for X-ray analysis. The results are shown in Figure 3.



Scheme 4. Reaction of spirocyclohexyl-1,2,4-trithiolane 1-*S* oxide **3** with **4**.

The sulfine fragment incorporated in complex **8** is coordinated by an $\eta^2$ mode and the complex has a distorted square-planar coordination sphere. The structure is comparable with that reported for the 9*H*-fluorene-9-thione-*S*-oxide complex.[17] The P1–Pt bond located in the *trans* position to the oxidized sulfur atom has a length of 2.2867(16) Å and the value for this bond length falls at the higher end of the range (2.25–2.30 Å) found for thioketone complexes.[9,10,18,19] In contrast to that found in the structure of **6**, the sulfur–platinum bond in **8** is remarkably longer [2.3338(18) Å] than those found in thioketone complexes (2.27–2.29 Å).[9,10,18,19] In the registered spectra of the crude product, there is no indication for the formation of **6** or **7**.

Taking this into account, the reactions of 1,2,4-trithiolane **1** and of the oxides **2** and **3** likely proceed in the first step by insertion of the $Pt^0$ complex fragment into the sulfur–sulfur bond of the 1,2,4-trithiolane ring.[9,11b,13] Ring contraction of the six-membered platinacycles formed, by expulsion of a thioketone or sulfine, leads to the four-membered platinacycles **5** and **7**, respectively. The former thioether sulfur atom is bonded to the platinum atom. In the last step, the thioketone or sulfine is complexed by a second equivalent of **4** to yield **6** or **8**, respectively. The exclusive formation of **5** and **8** in the reaction of the 1-*S*-oxide **3** with **4** suggests the favoured formation of thiolato ligands instead of sulfenato ligands in this system.

## Conclusions

In summary, the reactions of spirocylcohexyl-1,2,4-trithiolane **1** and of its 4-*S*- and 1-*S*-oxide, **2** and **3**, respectively, proceed by insertion of the $Pt^0$ complex fragment into the sulfur–sulfur bond and subsequent ring contraction by expulsion of a thioketone or sulfine. The reactions yield the thioketone complex **6** and dithiolato complex **5**, as well as their mono *S*-oxides **8** and **7**. Comparison of the molecular structures of the oxidized and nonoxidized complexes shows an elongation of the sulfenato–platinum bond as well as the elongation of the platinum–phosphorus bond in the corresponding *trans* position. Selective extrusion of a sulfine instead of the thioketone in the case of **3** suggests that the formation of thiolato–platinum bonds is energetically favoured over sulfenato–platinum bonds.

## Experimental Section

**General:** Melting points were determined with an AXIOLAB microscope with a TMHS 600 heating plate and are uncorrected. $^1H$-, $^{31}P$- and $^{13}C$ NMR spectra were determined with BRUKER DRX 400 or BRUKER DRX 200 spectrometers at 30 °C; chemical shifts are referred to the protons of the solvent or 85% $H_3PO_4$. $^{31}P$- and $^{13}C$ NMR spectra are proton decoupled. IR spectra were recorded with a PERKIN ELMER System 2000 FT-IR spectrome-

ter. Mass spectra were recorded with a FINNIGAN MAT SSQ 710 mass spectrometer. Elemental analyses were determined with a LECO CHNS-932. All reactions were performed under argon, and solvents were dried by using sodium/benzophenone. Starting materials 7,14,15-trithia-dispiro[5.1.5.2]pentadecane (**1**)[20] and the $Pt^0$ complex **4**[18] were prepared according to the literature procedures.

**Oxidation of Spirocyclohexyl-1,2,4-trithiolane 1:** *m*-CPBA (70%, 1.2 g, 5.4 mmol) dissolved in $CH_2Cl_2$ (10 mL) was added in small portions to a solution of spirocyclohexyl-1,2,4-trithiolane **1** (1 g, 3.8 mmol) in $CH_2Cl_2$ (20 mL) at 0 °C. The reaction mixture was stirred for an additional 2 h and subsequently washed with a diluted aqueous solution of $NaHCO_3$. The organic layer was separated, dried with $Na_2SO_4$, and reduced to dryness, and the residue was subjected to column chromatography to yield the 1-*S*-oxide **3** and the 4-*S*-oxide **2**, as well as a mixture of higher oxides.

**Spirocyclohexyl-1,2,4-trithiolane 1-*S*-Oxide 3:** Colourless crystals. Yield: 70 mg (6.6%). M.p. 46 °C. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 2.25–2.1 (m, 4 H), 2.1–1.9 (m, 4 H), 1.8–1.3 (m, 12 H) ppm. $^{13}$C NMR (50 MHz, $CDCl_3$): $\delta$ = 95.5 (q-C), 82.3 (q-C), 49.5, 43.6, 36.8, 32.4, 26.8, 26.1, 25.6, 25.0, 24.2, 23 ppm. IR (KBr): $\tilde{\nu}$ = 2920 (s), 1447 (s), 1098 [s, (S=O)] $cm^{-1}$. $C_{12}H_{20}OS_3$ (277.49): calcd. C 52.13, H 7.29, S 34.79; found C 52.15, H 6.59, S 35.01.

**Spirocyclohexyl-1,2,4-trithiolane 4-*S*-Oxide 2:** Colourless crystals. Yield: 240 mg (23%). M.p. 115 °C. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 2.09 (m), 1.90 (dt), 1.78 (m), 1.63 (m), 1.33 (m) ppm. $^{13}$C NMR (50 MHz, $CDCl_3$): $\delta$ = 84.6 (q-C), 33.7, 28.2, 25.2, 24.6, 23.1 ppm. IR (KBr): $\tilde{\nu}$ = 2931 (s), 1443 (s), 1067 [s, (S=O)] $cm^{-1}$. $C_{12}H_{20}OS_3$ (277.49): calcd. C 52.13, H 7.29, S 34.79; found C 52.06, H 7.21, S 34.92.

**Reaction of Spirocyclohexyl 1,2,4-Trithiolane 1 with [Pt($\eta^2$-nb)-($PPh_3$)$_2$] (4):** A portion of spirocyclohexyl-1,2,4-trithiolane **1** (30 mg, 0.11 mmol) was added to a solution of **4** (120 mg, 0.15 mmol) in toluene (10 mL). The solution immediately turned red and was stirred for an additional 3 h at 50 °C. The formation of the dithiolato complex **5** and the thioketone complex **6** in a 1:1 ratio was monitored by TLC. The solvent was reduced to dryness, and the crude product was washed with diethyl ether. The residue was dissolved in thf (10 mL) and filtered through silica gel. The solvent was reduced (to 5 mL), and the mixture was stored in a flask with pentane (10 mL). After 1 d, the dithiolato complex **5** was obtained. Yellow crystals. Yield: 40 mg (64%). M.p. 275 °C dec. $^1$H NMR (400 MHz, $CD_2Cl_2$): $\delta$ = 7.44 (m, 12 H), 7.30 (m, 6 H), 7.20 (m, 12 H), 1.86 (m, 4 H), 1.44 (m, 4 H), 1.25 (m, 2 H) ppm. $^{13}$C NMR (100 MHz, $CD_2Cl_2$): $\delta$ = 135.0 (t, $J_{C,P}$ = 5.5 Hz), 131.0 (m), 130.5, 127.9 (t, $J_{C,P}$ = 5.2 Hz), 68.1 (s, $^2J_{C,Pt}$ = 58 Hz), 50.5 (s, $^3J_{C,Pt}$ = 23 Hz), 25.9, 23.3 ppm. $^{31}$P{$^1$H} NMR (81 MHz, $CDCl_3$): $\delta$ = 24.76 (s, $^1J_{P,Pt}$ = 2971 Hz) ppm. IR (KBr): $\tilde{\nu}$ = 3073, 3052, 2925, 2850, 1967 (w), 1903 (w), 1820 (w), 1628 (s br.), 1480, 1434 (s), 1185, 1095 (s), 1028, 1014, 998, 743 (s), 693 (s), 542/525/515/497 ($PC_3$) $cm^{-1}$. MS (FAB): *m*/*z* (%) = 865 (0.5) $[M]^+$, 752 (1) $[M - (S{=}C(CH_2)_5)]^+$, 718 $[(Ph_3P)_2Pt]^+$, 307 (100). $C_{42}H_{40}P_2PtS_2$ (865.92): calcd. C 58.26, H 4.66, S 7.41; found C 58.26, H 4.74, S 7.19.

**Reaction of Spirocyclohexyl 1,2,4-trithiolane 4-*S*-Oxide 2 with [Pt($\eta^2$-nb)($PPh_3$)$_2$] (4):** The reaction was carried out in a manner similar to that with the unoxidized spirocyclohexyl 1,2,4-trithiolane **1**, except with spirocyclohexyl-1,2,4-trithiolane 4-*S*-oxide **2** (31 mg, 0.11 mmol). TLC as well as $^{31}$P NMR spectroscopy of the crude product showed the formation of a 1:1 mixture of **6** and **7**. In analogy to **5** the sulfenato thiolato complex **7** was isolated by chromatography and subsequent crystallization. Yellow crystals. Yield: 35 mg (52%). M.p. 222 °C dec. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 7.50–7.18 (m, 30 H), 1.98–1.3 (m, 10 H) ppm. $^{31}$P{$^1$H} NMR (81 MHz, $CDCl_3$): $\delta$ = 21.0 (d, $^2J_{P,P}$ = 16, $^1J_{P,Pt}$ = 3324 Hz), 19.8 (d, $^2J_{P,P}$ = 16, $^1J_{P,Pt}$ = 2343 Hz) ppm. IR (KBr): $\tilde{\nu}$ = 3054, 2927, 2852, 1969 (w), 1818 (w), 1632 (s br.), 1481, 1435 (s), 1185, 1096 (s), 1019, 998, 995 (br.)/955 (br.) (S=O), 744 (s), 693 (s), 539/523/513/497 ($PC_3$) $cm^{-1}$. MS (FAB): *m*/*z* (%) = 882 (4), 767 (24) $[M - (S{=}C(CH_2)_5)]^+$, 718 (20) $[(Ph_3P)_2Pt]^+$. $C_{42}H_{40}OP_2PtS_2$ (881.92): calcd. C 57.20, H 4.57, S 7.27; found C 56.71, H 4.61, S 7.02.

**Reaction of Spirocyclohexyl-1,2,4-trithiolane 1-*S*-Oxide 3 with [Pt($\eta^2$-nb)($PPh_3$)$_2$] (4):** A portion of spirocyclohexyl 1,2,4-trithiolane 1-*S*-oxide **3** (25 mg, 0.09 mmol) was added to a solution of **4** (120 mg, 0.15 mmol) in toluene (10 mL) at room temperature. The colour of the reaction mixture became slightly yellow, and after some minutes, a solid precipitated. The formation of the dithiolato complex **5** and the sulfine complex **8** was confirmed by TLC. The solvent was evaporated, and residue was subjected to column chromatography (THF/hexane, 1:2, $SiO_2$). The first substantial fraction was assigned to the dithiolato complex **5**, and second fraction contained the sulfine complex **8**; this fraction was collected to yield the pure sulfine complex **8**. White crystals. Yield: 25 mg (40%). M. p. 193 °C dec. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 7.33 (m, 6 H), 7.24 (m, 12 H), 7.15 (m, 12 H), 2.43 (d, $J_{H,H}$ = 13 Hz), 1.57 (m, 1 H), 1.49 (m, 3 H), 1.41 (m, 2 H), 1.09 (m, 1 H), 1.05 (m, 1 H), 0.84 (m, 1 H) ppm. $^{13}$C NMR (100 MHz, $CD_2Cl_2$): $\delta$ = 134.2 (m, *ipso*-C), 134.0 (m, Ph-C), 129.8 (s, Ph-C), 128.4 (s, Ph-C), 127.8 (m, Ph-C), 83.4 [d, $^2J$(C,P) = 53 Hz], 33.0 (s br.), 32.4 (d, $J_{C,P}$ = 6 Hz), 29.1 (d, $J_{C,P}$ = 8 Hz), 28.7, 26.6 ppm. $^{31}$P{$^1$H} NMR (81 MHz, $CDCl_3$): $\delta$ = 27.4 (d, $^2J_{P,P}$ = 24, $^1J_{P,Pt}$ = 3817 Hz), 26.4 (d, $^2J_{P,P}$ = 24, $^1J_{P,Pt}$ = 3075 Hz) ppm. IR (KBr): $\tilde{\nu}$ = 3072, 3053, 2923, 2847, 1968 (w), 1900 (w), 1816 (w), 1634 (s br.), 1480, 1434 (s), 1183, 1095 (s), 1027, 1011, 997, 983 (S=O), 743 (s), 695 (s), 538/521/510/497 (PC3) $cm^{-1}$. MS (FAB): *m*/*z* (%) = 850 (15), 719 (100) $[(Ph_3P)_2Pt]^+$. $C_{42}H_{40}OP_2PtS$ (849.86): calcd. C 59.36, H 4.74, S 3.77; found C 59.23, H 4.86, S 3.43.

**Synthesis of the Cyclohexanethione Complex 6:** Cyclohexanon diethyl ketal (1 g, 5.8 mmol) was dissolved in nonane (30 mL). A stream of hydrogen sulfide was passed through the reaction mixture, and a few drops of concentrated sulfuric acid were added. The mixture became red. After 30 min, the excess hydrogen sulfide was removed by passing a stream of argon through. Solid $NaHCO_3$ was added, and the organic layer was washed with water and dried with $Na_2SO_4$. The nonane was distilled off under reduced pressure, and cyclohexanthione was trapped in a cooling trap as a solution in nonane. Complex **4** (80 mg, 0.1 mmol) in toluene (10 mL) was added to this solution. The solvent was evaporated, and the residue was washed with diethyl ether, dissolved in thf (15 mL) and filtered over silica gel. The solvent was reduced (to 3 mL), and the mixture was stored in a flask with pentane (20 mL). After some days, pure thioketone complex **6** crystallized. White crystals. Yield: 50 mg (60%). M.p. 234 °C dec. $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 7.39–7.30 (m, 12 H), 7.24–7.11 (m, 18 H); 1.6–1.4 (m, 9 H), 0.87 (m, 1 H) ppm. $^{13}$C NMR (100 MHz, $CDCl_3$): $\delta$ = 135.4–133.4 (m), 133.8 (m), 129.2 (m), 127.3 (m), 86.3 (d, $^2J_{C,P}$ = 55 Hz), 43.8, 33.1 (d, $^3J_{C,P}$ = 8.5, $^2J_{C,Pt}$ = 45 Hz), 27.4 ppm. $^{31}$P{$^1$H} NMR (81 MHz, $CDCl_3$): $\delta$ = 28.2 (d, $^2J_{P,P}$ = 16, $^1J_{P,Pt}$ = 4600 Hz), 27.0 (d, $^2J_{P,P}$ = 16, $^1J_{P,Pt}$ = 2838 Hz) ppm. IR (KBr): $\tilde{\nu}$ = 3052, 2921, 2844, 1964 (w), 1626 (br.), 1479, 1434 (s), 1183, 1094 (s), 1027, 1014, 998, 742, 695 (s), 542/521/511/497 ($PC_3$) $cm^{-1}$. MS (FAB): *m*/*z* (%) = 719 (1) $[M - (S{=}C(CH_2)_5)]^+$. $C_{42}H_{40}P_2PtS$ (833.86): calcd. C 60.49, H 4.83, S 3.85; found C 60.19, H 4.82, S 3.67.

**Crystal Structure Determination:** The intensity data for the compounds were collected on a Nonius KappaCCD diffractometer by

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

using graphite-monochromated Mo-$K_\alpha$ radiation. Data were corrected for Lorentz and polarization effects and for absorption effects.[21–23] The structures were solved by direct methods (SHELXS[24]) and refined by full-matrix least-squares techniques against $F_o^2$ (SHELXL-97[25]). All hydrogen atoms of the structures were included at calculated positions with fixed thermal parameters. With the exception of the carbon atom C1 in compound **8**, all non-disordered, non-hydrogen atoms were refined anisotropically.[25] The oxygen atom in complex **8** had a 50:50 occupancy disorder over two positions, we therefore will not discuss the S–O bond length for the compound. Ortep-3 for Windows[26] was used for the structure representations.

**Crystal Data for 5:** $C_{42}H_{40}P_2PtS_2$, $M_r$ = 865.89 g mol$^{-1}$, colourless prism, size 0.02 × 0.02 × 0.02 mm, triclinic, space group $P\bar{1}$, $a$ = 10.4720(2), $b$ = 11.4799(3), $c$ = 16.6495(3) Å, $\alpha$ = 75.337(1), $\beta$ = 73.691(1), $\gamma$ = 82.905(1)°, $V$ = 1855.49(7) Å$^3$, $T$ = –90 °C, $Z$ = 2, $\rho_{calcd.}$ = 1.550 g cm$^{-3}$, $\mu$(Mo-$K_\alpha$) = 40.09 cm$^{-1}$, multiscan, trans$_{min}$: 0.5208, trans$_{max}$: 0.6615, $F$(000) = 864, 13452 reflections in $h$(–13/13), $k$(–14/14), $l$(–21/20), measured in the range 2.11° ≤ $\Theta$ ≤ 27.31°, completeness $\Theta_{max}$ = 98.9%, 8262 independent reflections, $R_{int}$ = 0.0189, 7656 reflections with $F_o > 4\sigma(F_o)$, 424 parameters, 0 restraints, $R_{1obs}$ = 0.0233, $wR_{2obs}$ = 0.0560, $R_{1all}$ = 0.0269, $wR_{2all}$ = 0.0579, GOOF = 1.015, largest difference peak and hole: 0.968/–1.061 e Å$^{-3}$.

**Crystal Data for 7:** $C_{42}H_{40}OP_2PtS_2$, $M_r$ = 881.89 g mol$^{-1}$, colourless prism, size 0.02 × 0.02 × 0.01 mm, triclinic, space group $P\bar{1}$, $a$ = 10.5086(2), $b$ = 11.3733(2), $c$ = 16.6699(4) Å, $\alpha$ = 76.040(1), $\beta$ = 74.247(1), $\gamma$ = 83.006(1)°, $V$ = 1857.50(7) Å$^3$, $T$ = –90 °C, $Z$ = 2, $\rho_{calcd.}$ = 1.577 g cm$^{-3}$, $\mu$ (Mo-$K_\alpha$) = 40.08 cm$^{-1}$, multiscan, trans$_{min}$: 0.6680, trans$_{max}$: 0.7621, $F$(000) = 880, 13298 reflections in $h$(–13/13), $k$(–14/14), $l$(–21/20), measured in the range 2.02° ≤ $\Theta$ ≤ 27.46°, completeness $\Theta_{max}$ = 99.4%, 8451 independent reflections, $R_{int}$ = 0.0184, 8026 reflections with $F_o > 4\sigma(F_o)$, 433 parameters, 0 restraints, $R_{1obs}$ = 0.0223, $wR_{2obs}$ = 0.0545, $R_{1all}$ = 0.0244, $wR_{2all}$ = 0.0556, GOOF = 1.023, largest difference peak and hole: 0.939/–1.383 e Å$^{-3}$.

**Crystal Data for 8:** $C_{42}H_{40}OP_2PtS$, $M_r$ = 849.83 g mol$^{-1}$, colourless prism, size 0.05 × 0.05 × 0.05 mm, orthorhombic, space group *Pbca*, $a$ = 16.0302(3), $b$ = 16.2448(4), $c$ = 27.5941(6) Å, $V$ = 7185.7(3) Å$^3$, $T$ = –90 °C, $Z$ = 8, $\rho_{calcd.}$ = 1.571 g cm$^{-3}$, $\mu$ (Mo-$K_\alpha$) = 40.85 cm$^{-1}$, multiscan, trans$_{min}$: 0.4608, trans$_{max}$: 0.5615, $F$(000) = 3392, 43387 reflections in $h$(–20/17), $k$(–17/21), $l$(–33/35), measured in the range 2.61° ≤ $\Theta$ ≤ 27.54°, completeness $\Theta_{max}$ = 99.2%, 8219 independent reflections, $R_{int}$ = 0.1025, 4772 reflections with $F_o > 4\sigma(F_o)$, 429 parameters, 0 restraints, $R_{1obs}$ = 0.0528, $wR_{2obs}$ = 0.0948, $R_{1all}$ = 0.1191, $wR_{2all}$ = 0.1134, GOOF = 0.987, largest difference peak and hole: 2.072/–3.542 e Å$^{-3}$.

CCDC-655294 (**5**), -655295 (**7**), and -655296 (**8**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see footnote on the first page of this article): The IR spectra of complexes **5**–**8** are included.

# Synthesis, Characterization, and Sensitizing Properties of Heteroleptic $Ru^{II}$ Complexes Based on 2,6-Bis(1-pyrazolyl)pyridine and 2,2′-Bipyridine-4,4′-dicarboxylic Acid Ligands

**Athanassios I. Philippopoulos,*[a][‡] Aris Terzis,[b] Catherine P. Raptopoulou,[b] Vincent J. Catalano,[c] and Polycarpos Falaras*[a]**

**Keywords:** 2,6-Bis(1-pyrazolyl)pyridine / Heteroleptic $Ru^{II}$ complexes / Dye-sensitized solar cells / Ruthenium / Protonation

Starting from the $Ru(bpp)Cl_3$ precursor (**1**), a family of novel heteroleptic $Ru^{II}$ complexes of the general formulae [Ru(bpp)(dcbpyH)(X)] [X = $Cl^-$ (**2a**), $NCS^-$, (**3**)] and Na[Ru(bpp)(dcbpy)(CN)] (**4**) with the ligands 2,6-bis(1-pyrazolyl)pyridine (bpp) and 2,2′-bipyridine-4,4′-dicarboxylic acid ($dcbpyH_2$) has been synthesized, spectroscopically characterized, and attached to nanocrystalline $TiO_2$ electrodes to be tested as solar cell sensitizers. Addition of HCl to (**2a**) led to the corresponding cationic derivative $[Ru(bpp)(dcbpyH_2)Cl]Cl$ (**2b**). All complexes were characterized by FT-IR, FT-Raman, UV/Vis, $^1H$ NMR spectroscopy, elemental analysis, and mass spectrometry. Complex **4** and the previously reported $[Ru(bdmpp)(dcbpyH_2)Cl](PF_6)$ (**5**) [bdmpp is 2,6-bis(3,5-dimethyl-1-pyrazolyl)pyridine] were characterized by single-crystal X-ray diffraction. The photo-electochemical properties of the dyes **2**–**4** were investigated and the efficiency of the corresponding dye-sensitized solar cells was compared to the sensitizing performance of the *cis*-$[Ru(dcbpyH)_2(NCS)_2](NBu_4)_2$ (**N719**) dye.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2007)

## Introduction

During the last decade, nanocrystalline titania films sensitized by transition-metal complexes have been extensively used for the conversion of light to electricity, because of their high efficiency (approximately 10%) and low cost.[1] The so-called dye-sensitized solar cells (DSSCs) consist of a photoanode, a sensitizer chemically adsorbed on the surface of a mesoporous oxide layer, and a counter electrode sandwiching an electrolyte containing the redox couple (usually the $I^-/I_3^-$ system in an organic medium).[2] Undoubtedly one of the most important parts of the cell is the sensitizer, mainly a ruthenium(II) polypyridine complex bearing suitable anchoring groups (carboxylic or phosphonic) for efficient grafting to the oxide surface via ester-type bond formation.[3] These dyes have to fulfill many other requirements like intense absorption in the visible region, efficient electron injection to the conduction band of the semiconductor, high stability of the sensitizer molecule, and reversibility of its redox chemistry.[4] Also, the electron transfer from the excited state of the dye to the semiconductor ($TiO_2$) should be very fast in comparison with decay to the ground state of the dye. Broad spectral response covering the entire visible range extending to the near-IR region is one of the most important prerequisites of a potential molecular sensitizer.

There is now a significant scientific effort for the development of efficient sensitizers with improved spectroscopic-photovoltaic characteristics for solar cell applications. Thus, a series of homoleptic $[Ru(L)_3]^{2+}$ and heteroleptic $[Ru(L^1)(L^2)(L^3)]^{2+}$, $[Ru(L^1)(L^2)(NCS)_2]$ (L = substituted bipyridyl with appropriate anchoring groups) ruthenium(II) complexes have been prepared.[5,6] So far one of the best sensitizers is *cis*-$[Ru(dcbpyH_2)_2(NCS)_2]$, known as N3, with a solar to electricity efficiency as high as 11.04%.[7] Moreover, a cell with extra pure monoprotonated *cis*-$[Ru(dcbpyH)_2(NCS)_2](NBu_4)_2$ (**N719** sensitizer), equipped with an antireflecting coating, gave an overall conversion efficiency of 11.18%. Use of modified ligands endowed with hydrophobic groups[8] and supramolecular functionalities has been proved to facilitate dye/redox couple interaction and dye regeneration.[9] On the basis of a judicious substitution of the bidentate by a tridentate ligand, a tris(isothiocyanato)-(4,4′,4′′-tricarboxy-2,2′:6,2′′-terpyridine)ruthenium(II) complex, so called black dye,[10] with a conversion efficiency of 10.4%, was proved to exhibit similar photovoltaic properties to the N3 dye. To further explore this possibility, 2,6-bis(3,5-dimethyl-1-pyrazolyl)pyridine

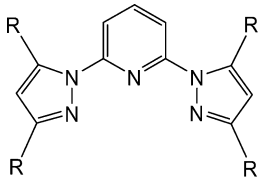
(bdmpp)[11] (Scheme 1), a tridentate analogue to the terpyridine ligand, has been introduced in a $Ru^{II}$ metal center.[12]



bpp: R = H; bdmpp: R = Me

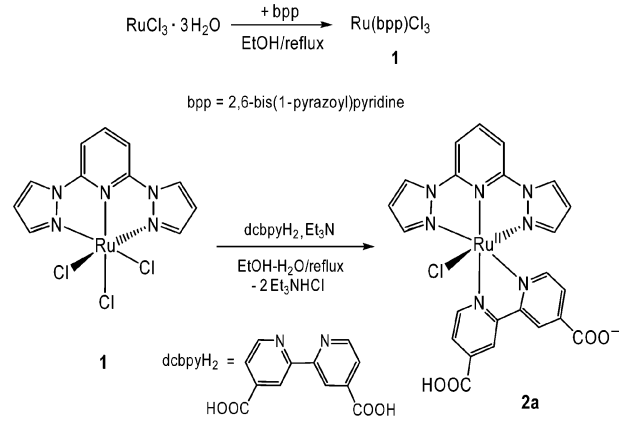
Scheme 1. Structural formula of the ligands bpp and bdmpp.

In this respect, in our laboratory, we set out to synthesize ruthenium(II) molecular sensitizers using both the bdmpp and $dcbpyH_2$ ligands. Such a synthesis allows us to study the properties of the complexes and evaluate their influence on the performance of the corresponding dye-sensitized solar cells. As a result, the heteroleptic complexes $[Ru(bdmpp)(dcbpyH_2)(X)](PF_6)$ have been synthesized and successfully examined for the sensitization process.[13] In a more systematic approach towards this aim, i.e. the preparation of alternatives for the N3 and the corresponding black dye, in this paper, we report the synthesis and spectroscopic characterization of a series of neutral [Ru(bpp)(dcbpyH)(X)] (X = $Cl^-$, $NCS^-$) (**2a**, **3**), cationic $[Ru(bpp)(dcbpyH_2)Cl]Cl$ (**2b**), and anionic Na[Ru(bpp)-(dcbpy)(CN)] (**4**) ruthenium(II) complexes containing the tridentate ligand 2,6-bis(1-pyrazolyl)pyridine. Furthermore, their photo-electrochemical properties have been studied in sandwich-type solid-state nanocrystalline $TiO_2$ cells using a composite polymer redox electrolyte, namely PEO/$TiO_2$/$I^-$/$I_3^-$,[14] (PEO = polyethylene oxide, MW = $2 \times 10^6$) and compared to those of the corresponding $[Ru(bdmpp)(dcbpyH_2)-(X)](PF_6)$.[13]

## Results and Discussion

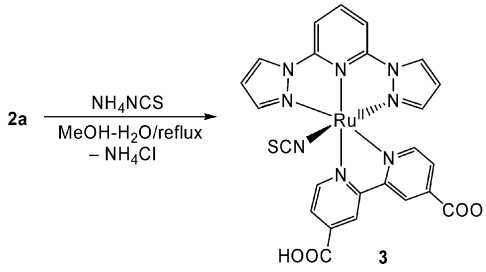
### Syntheses

The complexes **1**–**4** were synthesized by a route analogous to that reported previously.[13] The synthetic procedure for the preparation of complexes **1**–**2a** is shown in Scheme 2. Reaction of the precursor $Ru(bpp)Cl_3$ (**1**)[15] with the 2,2′-bipyridine-4,4′-dicarboxylic acid ligand in refluxing ethanol/water (1:1, v/v) and in the presence of $Et_3N$ (acting as both reducing and deprotonating agent) afforded selectively the heteroleptic neutral complex [Ru(bpp)(dcbpyH)-Cl] (**2a**), which was isolated as a red-brown microcrystalline solid in 97% yield. It is a stable solid that does not decompose after heating at 215 °C. Its structure is similar to that reported for the [Ru(bmipy)(dcbpyH)I] [bmipy = 2,6-bis(1-methylbenzimidazol-2-yl)pyridine compound,[16] taking into consideration, that both octahedral complexes bear a tridentate (coordinated via nitrogen atoms), a halide, and a deprotonated (dcbpyH) 2,2′-bipyridine-4,4′-dicarboxylic acid] ligands around the $Ru^{II}$ metal center.



Scheme 2. Stepwise formation of complexes **1**, **2a**.

In a boiling methanol/water solution (1:1, v/v) containing an excess of the amphidentate thiocyanate ligand, complex **2a** undergoes metathesis reaction resulting in the isothiocyanato complex [Ru(bpp)(dcbpyH)(NCS)] (**3**), that was isolated as an orange-red solid in 89% yield [Equation (1)]. This complex shows a remarkable thermal stability and decomposes without melting at 261–262 °C.



(1)

Monitoring of the reaction by FT-IR and $^1H$ NMR spectroscopy revealed that the reaction was completed after 4 h of heating. Elemental analysis data for complexes **2a** and **3** are consistent with the calculated composition of the proposed structure. This is also supported by FT-IR spectroscopy (see corresponding section concerning IR spectroscopy) and by derivatization, i.e. formation of the $[Ru(bpp)(dcbpyH_2)Cl]Cl$ complex (**2b**), where both carboxylate groups are protonated (vide infra).

In addition, compound **2a** reacts in the presence of an excess of NaCN, under the same conditions, to give the cyano complex Na[Ru(bpp)(dcbpy)(CN)] (**4**) as an orange solid in 67.5% yield [Equation (2)]. Complex **4** decomposes upon melting at 249 °C.

Addition of an aqueous solution of HCl (excess), to **2a** is accompanied by protonation of the carboxylate ($–COO^-$) group of the bidentate ligand (dcbpyH), affording quantitatively the $[Ru(bpp)(dcbpyH_2)Cl]Cl$ dye (**2b**), as a brown-black solid [Equation (3)].[17] It is a stable solid that does not decompose after heating at 240 °C.

Following a simple purification step, i.e. crystallization of the crude products, all complexes have been obtained in high yield as air stable and analytically pure solids. Therefore, the use of time-consuming column chromatography

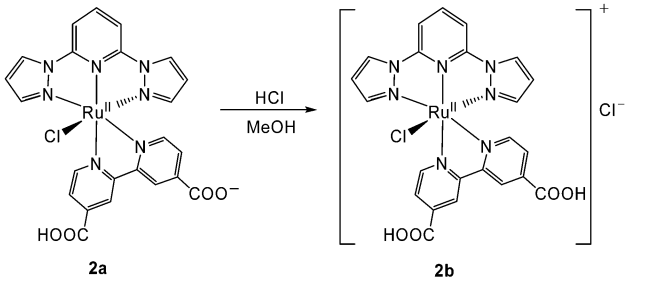
(2)



(3)

purification is avoided. In addition, in the case of complex **3**, only the N-bonded isomer was isolated (see IR-Raman section).[18] This is very important, since ruthenium bipyridine complexes with thiocyanate ligands typically yield an isomeric mixture of N- and S-bonded isomers.[15,19] Compounds **2**–**3** were found to be soluble in dimethylformamide (DMF), dimethyl sulfoxide (DMSO), and slightly soluble in methanol. The corresponding complex **4** dissolves very well in water and is less soluble in DMSO. The composition of the ruthenium(II) complexes **2a**–**4** was confirmed by elemental analyses and their spectroscopic properties were examined by FT-IR, FT-Raman, UV/Vis and $^1H$ NMR spectroscopy. The molecular composition of all compounds was further confirmed by mass spectrometric data (electrospray). The molecular structure of **4**·7.5$H_2O$·0.5$CH_3CN$ was determined by single-crystal X-ray diffraction (vide infra). Also the corresponding [Ru(bdmpp)(dcbpy$H_2$)Cl]-($PF_6$) sensitizer **5**[13b] was characterized by X-ray crystallography and the crystallographic data were compared with those of **4**.

## Characterization

### *IR-Raman Spectroscopic Data*

The IR spectra of complexes **2a** and **3** are almost identical in the region of 4000–400 $cm^{-1}$ as expected for isostructural compounds, except for the presence of a strong NCS band (in complex **3**) at 2109 $cm^{-1}$ which is assigned to the $\nu_{as}$(NCS) mode. This band appears at a position close to that of related ruthenium(II) complexes for which N-bonding of the NCS group has been confirmed.[20] The presence of a less intense band at 815 $cm^{-1}$ is assigned to the $\nu_s$(C=S) stretching vibration.[21] The Raman band that is characteristic of the $\nu_{as}$(NCS) vibration appears at 2112 $cm^{-1}$, slightly shifted compared to the value observed by IR spectroscopy (Table 1). Both complexes exhibited a broad and medium intensity absorption band at 1718 and 1717 $cm^{-1}$ respectively which is assigned to the ν(C=O) stretching vibration. This band has a slightly higher frequency than that of [Ru(bdmpp)(dcbpy$H_2$)Cl]($PF_6$) (1715 $cm^{-1}$)[13b] and [Ru(bdmpp)(dcbpy$H_2$)(NCS)]($PF_6$) (1713 $cm^{-1}$) respectively[13a] which may be attributed to the higher electron density at the $Ru^{II}$ center of complexes bearing the methyl-substituted pyrazolyl-pyridine ligand bdmpp. The bands at 1628 and 1627 $cm^{-1}$ respectively, overlapping with the bpy bands[3c,19] at 1609 and 1610 $cm^{-1}$, are tentatively assigned to the antisymmetric carboxylate vibration $\nu_{as}(CO_2^-)$.[22] The cationic complex **2b** displays the ν(C=O) stretching vibration at 1718 $cm^{-1}$, while the ν(C–O) mode is present as a medium intensity band at 1230 $cm^{-1}$.[5a]

The absence of IR bands above 1700 $cm^{-1}$ in the anionic complex **4** indicates that no protonated C=O group is present. Instead, there is a very strong and broad band at 1600 $cm^{-1}$ which is assigned to the antisymmetric stretching vibration of $\nu_{as}(CO_2^-)$. The strong band at 1377 $cm^{-1}$ can probably be assigned to the symmetric vibration mode $\nu_s(CO_2^-)$ of the carboxylate group.[23] The presence of a terminal cyanido ligand in **4** is indicated by a medium intensity ν(CN) IR absorption band at 2077 $cm^{-1}$ and thus corroborates the molecular structure of **4** determined by X-ray crystallography (vide infra). This band appears at a position close to that of the cyanide ion in NaCN (ν(CN) = 2085 $cm^{-1}$). The ν(CN) frequency of **4** is comparable with those of similar ruthenium complexes $Na_4$[Ru(dcbpy)$_2$-(CN)$_2$] (2077 and 2059 $cm^{-1}$),[24] [Ru(ttp)(L)(CN)]($PF_6$)[25]

Table 1. Selected Raman and FT-IR spectroscopic data [$cm^{-1}$] of complexes **2**–**4**.

| Complexes | ν(N=C) | ν(C=O) | $\nu_{as}(CO_2)$ | ν(C=C) | ν(C=C) | ν(C=N) | $\nu_s(CO_2^-)$ | ν(C–O) |

[ttp = 4′-p-tolyl-2,2′:6′,2′′-terpyridine, L = bpy, ν(CN) = 2079 $cm^{-1}$; L = Phen, ν(CN) = 2075 $cm^{-1}$], and *cis*-[($Et_2$-dcbpy)$_2$Ru(CN)$_2$] [ν(CN) = 2085 and 1996 $cm^{-1}$], respectively.[26] Also it compares well with the stretching vibration of the osmium complex [Os($H_2$teterpy)(CN)$_3$](TBA)$_2$ [ν(CN) = 2076 $cm^{-1}$, $H_3$teterpy = 2,2′:6′,2′′-terpyridine-4,4′,4′′-tricarboxylic acid, TBA = tetrabutylammonium].[27] In addition, the Raman spectrum of complex **4** in crystalline form gave very well resolved bands indicative of the high purity of this material, confirming the presence of the characteristic ν(CN) mode as a medium intensity band at 2076 $cm^{-1}$.

Moreover, the Raman spectrum of **2b** reveals at low frequency a medium intensity band for the $\nu_s$(Ru–Cl) stretching mode at 335 $cm^{-1}$. This value compares well with that mentioned for [$RuCl_4$(MeCN)$_2$](N$Et_4$).[28]

### *NMR Spectroscopic Studies*

The $^1$H NMR spectra of all complexes show a similar pattern in the aromatic region, indicating that substitution of the chlorido ligand by pseudohalides takes place without significant changes in the octahedral geometry at the ruthenium atom. In all cases signal assignment is based on integration, splitting patterns, chemical shifts, $^1$H-$^1$H COSY experiments, and literature values concerning similar systems.[13,16]

The $^1$H NMR spectra of complexes **2**–**4** were recorded in $(CD_3)_2SO$ at ambient temperature and Figure 1 presents the characteristic spectrum of complex **2a**. In this solvent, the compound **2a** undergoes substitution of the chlorido ligand, because of its labile nature,[29] as evidenced in the $^1$H NMR spectrum of **2a** which shows the formation of new resonance signals next to the expected ones, after 14 h standing. For this reason, only data from freshly prepared samples provides a basis for proper interpretation. The aromatic region of the spectrum of complex **2a** displays six sharp (four doublets and two singlets) and well-resolved resonance signals at $\delta$ = 10.09 (H$^{21}$), 9.26 (H$^{18}$), 9.01 (H$^{15}$), 8.25 (H$^{20}$), 7.53 (H$^{12}$), and 7.35 (H$^{13}$) ppm respectively, attributable to the six protons of the 2,2′-bipyridine-4,4′-dicarboxylic acid ligand. In addition, the $^1$H NMR spectrum of **2a**, shows a multiplet signal at $\delta$ = 8.45 ppm for the three pyridyl hydrogen atoms ($C_6H_3$ moiety, H$^{5-7}$). Two doublet signals at $\delta$ = 9.28 (H$^{1,11}$), 7.40 (H$^{3,9}$) ppm and a pseudotriplet resonance at $\delta$ = 6.70 ppm (H$^{2,10}$) are due to the chemical equivalent pyrazolyl hydrogen atoms.

The low field singlet at $\delta$ = 10.09 ppm is assigned to the H$^{21}$ proton of dcbpyH that is close to the coordinated chlorine atom. This singlet signal is upfield shifted by 0.55 and 0.29 ppm respectively, compared to the isothiocyanato complex **3** and the cyano complex **4**. Both the H$^{18}$ and H$^{15}$ singlet resonances of complexes **3** and **4** are shifted upfield compared to the precursor (**2a**) by 0.22 (0.46) and 0.21 (0.39) ppm, respectively.

### *Electronic Spectra*

The UV/Vis absorption spectra of freshly prepared complexes **2**–**4** measured in DMSO are shown in Figure 2 and the corresponding electronic spectroscopic data are summarized in Table 2.

The high energy bands in the 294 to 313 nm range are assigned to π-π* charge-transfer transitions localized on bipyridine ligands.[30] The absorption bands in the visible region can be assigned to the metal-to-ligand charge transfer transition bands ($^1$MLCT), as mentioned for other Ru$^{II}$ polypyridyl complexes.[31] The UV/Vis spectra of **2** and **3** are similar displaying a broad band that consists of three absorption bands in the visible region at 480, 434, 384 (**2a**),

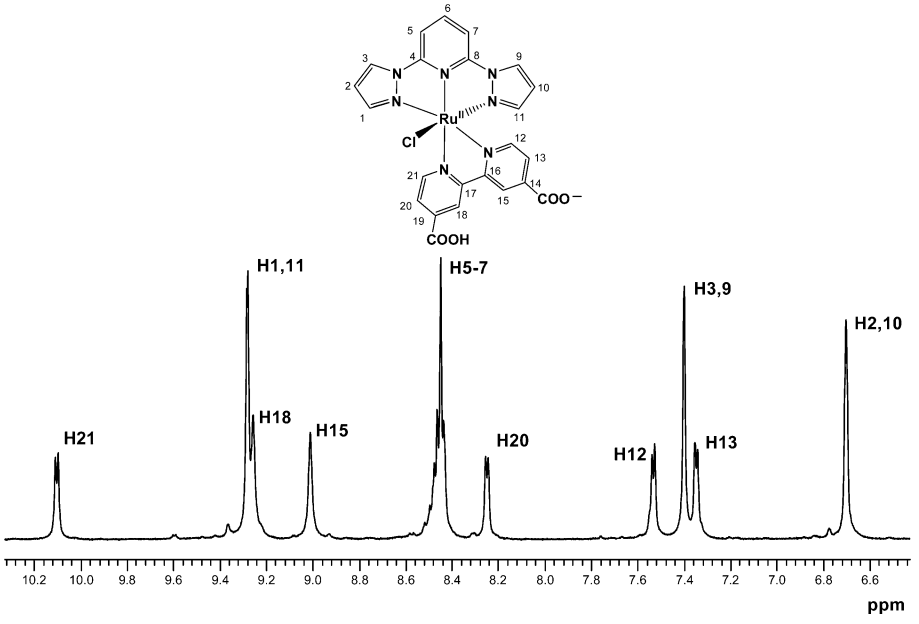

Figure 1. $^1$H NMR spectrum of complex [Ru(bpp)(dcbpyH)Cl] (**2a**) in $(CD_3)_2SO$ at ambient temperature. A numbering scheme showing our tentative assignment for NMR peaks is included.

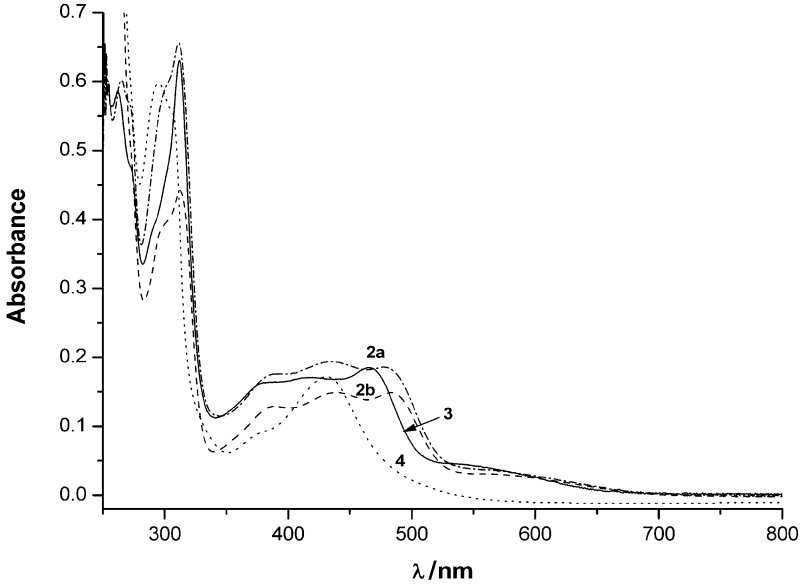

Figure 2. UV/Vis absorption spectra of **2a** (-.-), **2b** (···), **3** (—), and **4** (---) in dimethyl sulfoxide at 298 K.

Table 2. Electronic spectroscopic data of the complexes **2**–**4** measured in DMSO solution at 289 K.

| Complexes | Absorption data [$\lambda_{max}$ [nm] ($\varepsilon$, $10^3$ $M^{-1}$ $cm^{-1}$)] | | | |
|---|---|---|---|---|
| **2a** | 312 (25.5) | 384 (6.8) | 434 (7.3) | 480 (7.5) |
| **2b** | 313 (49.9) | 388 (14.6) | 438 (16.8) | 483 (16.8) |
| **3** | 312 (29.4) | 376 (7.5) | 418 (7.9) | 466 (8.6) |
| **4** | 307 (11.5) | – | 377 (1.9) | 430 (3.6) |

483, 438, 388 (**2b**), and 466, 418, 376 (**3**) nm, respectively. The visible spectrum of sensitizer **4** displays a broad band at 430 nm. The complexes **2a**, **3**, **4** maximum absorption wavelengths are blue shifted in the order $Cl^-$, $NCS^-$, $CN^-$, consistent with a decrease of electron density on the metal, as previously reported for ruthenium(II) dyes.[32] It is also worth mentioning that the absorption spectra of **2a**, **2b**, and **3** show a broad band at approximately 570 nm (530 nm for **3**), that expands in the near-IR region, up to 700 nm (approximately 610 nm for **3**). This behavior is very important for the photosensitization process as it permits harvesting and transformation of the less energetic photons.[10a] On the other hand, the $^1$MLCT bands of the cationic complex **2b** with fully protonated –COOH groups in the bipyridine ligand are slightly shifted toward the red compared to **2a** (from 480, 433, and 384 nm to 483, 438, and 388 nm).[33] It has to be mentioned that comparing complexes **2a** and **2b,** the extinction coefficient increases significantly. This behavior has also been verified by recording the spectra of the two dyes in amine-free dimethylformamide solution, where a similar increase of the extinction coefficient ($\varepsilon$) by about 25% was observed. This can be attributed to the different structure of the two complexes (**2a** is an internal salt while **2b** is a typical inorganic salt). In addition, for both complexes in DMF, a hypsochromic shift was observed ($\lambda_{max}$ = 456 nm for **2a** and $\lambda_{max}$ = 468 nm for **2b**). Finally, detailed analysis has shown that our complexes present no emission at ambient temperature in DMSO (**2a**–**3**) and aqueous solutions (**4**), respectively. The same result was confirmed with degassed solvents. Additionally, no emission signal was observed for dyes **2a**–**3** chemically attached on the surface of $TiO_2$ films. Indeed, emissive ruthenium(II) complexes incorporating the 2,6-bis(1-pyrazolyl)pyridine ligand have not been reported to date. This is mainly attributed to the fact that these complexes are expected to have low-lying triplet ligand field excited states ($^3$LF) that facilitate rapid nonradiative decay therefore decreasing the probability of radiative emission.[34] On the contrary luminescent complexes with terpy ligands of the type $[Ru(terpy)(bpy)L]^{2+}$ are well known, which are generally weak emitters at room temperature.[35] Accordingly, no room-temperature emission was observed for the *cis*-[2,2′-bipyridine-5,5′-$(CO_2H)_2$]$_2$Ru$(X)_2$ (X = $Cl^-$, $CN^-$, $NCS^-$) complexes.[36]

### *X-ray Diffraction Studies*

The solid-state structure of complex **4** was determined by single-crystal X-ray diffraction. For comparison reasons, the molecular structure of its analogue, the $Ru^{II}$ complex $[Ru(bdmpp)(dcbpyH_2)Cl](PF_6)$ (**5**), is described. The molecular structures of **4** and **5** are depicted in Figures 3 and 4, respectively.

Both complexes reveal distorted octahedral geometry around the ruthenium metal ion. Distortion results from the constrained bite angle of the chelating tridentate of 156.15(3)° and 156.5(3)° for N(1)–Ru–N(5), respectively. Also deviation from an octahedral geometry is evidenced from the short bite angle N(11)–Ru–N(12) of 77.68°(12) and 78.6°(3), respectively, as observed in [Ru(bdmpp)-(bpy)Cl]Cl·1.25$CHCl_3$,[37] [N(11)–Ru–N(21) 79.8°(5)], and in *cis*-$[Ru(dcbpyH_2)_2(NCS)_2]$·5.0DMSO,[38] [N(11)–Ru–N(21) 79.8°(5), N(31)–Ru–N(41) 79.1°(5)]. As a result of the constrained bite angle of the 2,6-bis(1-pyrazolyl)pyridine ligands, the ruthenium–nitrogen bond to the pyridine nitrogen [complex **4**, Ru–N(3) 1.987(3) Å; complex **5**,

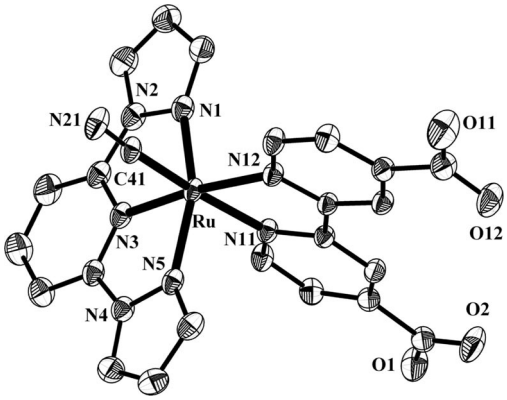

Figure 3. A perspective view of the anion **4**·7.5$H_2O$·0.5$CH_3CN$ in the solid state. Thermal ellipsoids are set at the 50% probability level. Hydrogen atoms and solvate (water and acetonitrile) molecules have been omitted for clarity. Selected bond lengths [Å] and bond angles [°] of **4**·7.5$H_2O$·0.5$CH_3CN$: Ru–N(1) 2.096(4), Ru–N(3) 1.987(3), Ru–N(5) 2.061(4), Ru–N(11) 2.109(3), Ru–N(12) 2.080(3), Ru–C(41) 1.999(4), N(1)–Ru–N(3) 77.8(14), N(1)–Ru–N(11) 95.0(13), N(1)–Ru–N(12) 106.6(13), Ru–C(41)–N(21) 176.1(4).

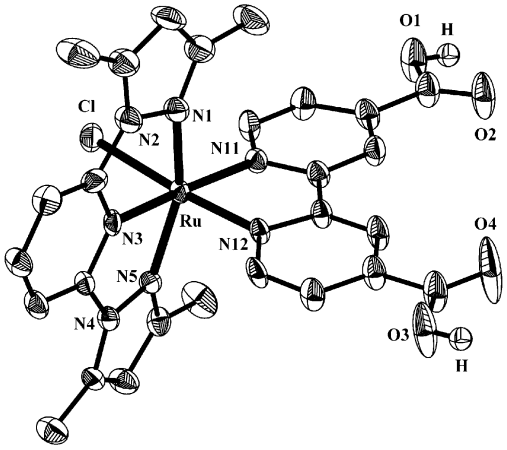

Figure 4. A perspective view of the cation **5**·2$CH_3CN$·0.5$CH_3OH$ (50% probability of thermal ellipsoids). Hydrogen atoms on the carboxylate moieties of the dcbpy$H_2$ are shown only. The remaining H-atoms and the solvate (water and acetonitrile) molecules have been omitted for clarity. Selected bond lengths [Å] and bond angles [°] of **5**·2$CH_3CN$·0.5$CH_3OH$: Ru–N(1) 2.086(8), Ru–N(3) 1.987(7), Ru–N(5) 2.069(7), Ru–N(11) 2.065(7), Ru–N(12) 2.024(7), Ru–Cl 2.403(3), N(1)–Ru–N(3) 79.0(3), N(1)–Ru–N(11) 99.5(3), N(12)–Ru–Cl 174.9(2), N(1)–Ru–Cl 86.9(2).

1.987(6) Å] is shorter than those belonging to the pyrazolyl substituents [complex **4**, Ru–N(1) 2.096(4) Å, Ru–N(5) 2.061(4) Å; complex **5**, 2.085(8) Å, 2.096(4) Å]. The ligands bpp and bdmpp chelate meridionally via the three nitrogen atoms, i.e. N(1), N(3), and N(5), forming a plane with one nitrogen [N(12) or N(11), respectively] of the functionalized 2,2′-bipyridine ligand. The second nitrogen atom [N(11) or N(12), respectively] of the dcbpy$H_2$ and the chlorido (cyanido) ligand occupies the axial positions. The Ru–Cl bond length of **5**·2$CH_3CN$·0.5$CH_3OH$ [2.403(2) Å] lies in the expected range for related $Ru^{II}$ complexes, [Ru(bdmpp)(bpy)Cl]Cl·1.25$CHCl_3$, [Ru–Cl 2.419(3) Å],[37] [Ru(bdmpp)($Me_2$bpy)Cl]($PF_6$)·1.25$CHCl_3$ [Ru–Cl 2.445(2) Å],[37] [Ru(dcbpy$H_2$)(cymene)Cl][$NO_3$] [Ru–Cl 2.3966(10) Å].[34] Likewise, the Ru–C41 bond length of the cyanido ligand in **4**·7.5$H_2O$·0.5$CH_3CN$ [1.999(4) Å] lies in the range observed for other anionic [Ru(CN)(py)(pc)]($NBu_4$) [pc = phthalocyanine, Ru–C 2.01(2) Å],[39] and cationic ruthenium cyano complexes [Ru(terpy)(phen)(CN)]($PF_6$) [Ru–C 2.004(3) Å].[40] The coordination geometry around the $Na^+$ cation is distorted octahedron comprised of water solvate molecules, whereas no interactions less than 3 Å are observed between the $Na^+$ and the oxygen atoms of the carboxylate groups. The separations of the oxygen atoms of the water molecules to the $Na^+$ cation lay in the range 2.249(9)–2.968(26) Å. In the structure of **4**, intermolecular distances in the range 2.752–3.268 Å between the solvate water molecules and the carboxylato oxygen atoms as well as the cyano nitrogen atom, result in an interesting hydrogen-bonding pattern, which contributes to the further stability of the lattice structure. The cations of **5** are doubly hydrogen bonded through the protonated carboxylate moieties of the dcbpy$H_2$ ligand giving rise to the formation of dimers [HO3···O2′ (1 – *x*, –*y*, 1 – *z*) 1.905 Å, O3···O2′ 2.698 Å, O3–HO3···O2′ 162.5°].

### *Electrochemistry*

The cyclic voltammograms were recorded in ca. $10^{-3}$ M aqueous solutions of the corresponding complexes using 0.1 M $NBu_4ClO_4$ as a supporting electrolyte, at a sweep rate of 100 mV $s^{-1}$. Well-defined reversible oxidation/reduction waves were obtained attributed to the $Ru^{II}/Ru^{III}$ redox couple. It has been observed that the cationic dye (**2b**) has higher oxidation potential (+0.73 vs. Ag/AgCl) than the neutral (**2a**) one (+0.68 vs. Ag/AgCl). Taking into account that the onset of the dye absorption spectra is the same, this implies that in the case of $TiO_2$ sensitization the energetic diagrams of the corresponding interfaces are different and therefore electron injection yield is expected to be larger for complex **2b** compared to **2a**.[50b]

### *Photovoltaic Performance*

The absorption spectra of the new dyes on $TiO_2$ films (after subtraction of background absorption from the $TiO_2$ and conductive glass) are shown in Figure 5. The absorption peaks for the chemisorbed dyes **2a**–**3** are all quite broad, compared with the corresponding dye peaks in dimethyl sulfoxide solution. It is easily observed that the absorption intensity of dye **2b** on the $TiO_2$ film is higher than that of **2a**, indicating that this complex is more efficiently adsorbed on the $TiO_2$ surface than **2a**. In fact, the amount of adsorbed dye to the surface of the $TiO_2$ films was determined by desorbing the dye from the $TiO_2$ surface into a 0.001 M NaOH aqueous solution. The number of adsorbed molecules of the dye adsorbed per square centimeter of geometrical surface area ($\Gamma$) for the four dyes **2a**–**4** is listed in Table 3. The $\Gamma$ value for dye **2b** was determined to be $1.6 \times 10^{-7}$ mol $cm^2$, which is about an order of magnitude higher than that for dye **2a** ($5.9 \times 10^{-8}$ mol $cm^2$). Therefore, upon sensitization, significant differences in $J_{sc}$ between the

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

two dyes are expected. The increased dye uptake in the case of a solar cell sensitized with dye **2b** (the $\Gamma$ value of **2b** is almost the same as that of N719[41]) results in increased short circuit photocurrent density ($J_{sc}$), mainly responsible for the higher conversion efficiency of complex **2b**. In fact, the $J_{sc}$ value of the **2b**-sensitized solar cell was about two times higher than that of the **2a**-sensitized solar cell, which was expected from the UV/Vis spectra. The low efficiency of dyes **2a**, **3**, and **4** is correlated with the lower absorption coefficient of these dyes (Table 2 and Figure 5) and/or to the decreased amount of dye molecules on the titania surface (Table 3).

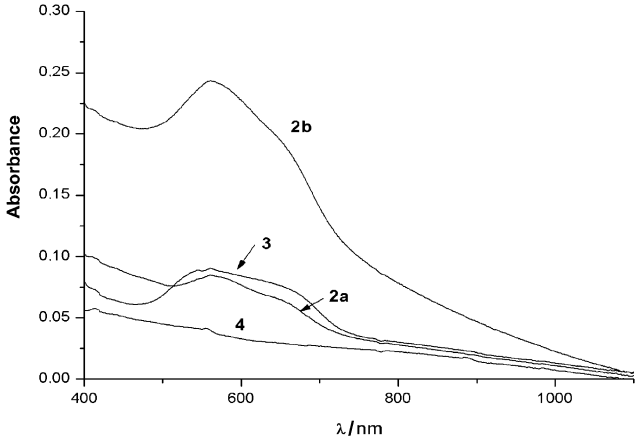

Figure 5. Absorption spectra of the four dyes **2**–**4** on $TiO_2$ electrodes.

Table 3. Photovoltaic performance (under standard AM 1.5 illumination conditions) of solid-state DSSCs using the $Ru^{II}$ dyes **2**–**5** and a PEO/$TiO_2$/$I^-$/$I_3^-$ composite polymer redox electrolyte [corresponding parameters: short circuit photocurrent density ($J_{sc}$); open circuit potential ($V_{oc}$); fill factor (*ff*) and power conversion efficiency ($\eta$), using the N719 dye are also given]. Surface concentration ($\Gamma$) of the chemisorbed dyes is also included.

| Dyes | $J_{sc}$ [mA cm$^2$] | $V_{oc}$ [mV] | *ff* | $\eta$ [%] | $\Gamma$ [mol cm$^2$] |
|---|---|---|---|---|---|
| **2a** | 1.56 | 541 | 0.58 | 0.49 | $5.9\times10^{-8}$ |
| **2b** | 3.32 | 580 | 0.58 | 1.12 | $1.6\times10^{-7}$ |
| **3** | 1.88 | 545 | 0.54 | 0.55 | $2.0\times10^{-8}$ |
| **4** | 1.46 | 532 | 0.58 | 0.45 | $7.0\times10^{-9}$ |
| **5** | 4.025 | 493 | 0.56 | 1.11 | – |
| N719 | 9.29 | 583 | 0.53 | 2.87 | $1.6\times10^{-7}$ |

The titania thin films (deposited on conductive glass substrates) were sensitized at ambient temperature for 12–15 h by immersing them into a c.a. $3\times10^{-4}$ M solution of the complexes in DMSO. To evaluate their sensitizing ability and compare their photovoltaic performance, the complexes **2**–**4** chemically attached on the titania electrodes, were incorporated in sandwich-type solid-state solar cells employing a composite polymer redox electrolyte (PEO/$TiO_2$/$I^-$/$I_3^-$) (PEO = polyethylene oxide, MW = $2\times10^6$)[14] and using a platinized TEC 8 counter electrode. The *cis*-[Ru(dcbpyH)$_2$(NCS)$_2$](NBu$_4$)$_2$ (**N719** dye, purchased from Solaronix) was used as a standard to compare the new sensitizers. Typical photocurrent-density photovoltage curves of DSSCs with the ruthenium dyes **2**–**4** (obtained at AM 1.5 simulated solar irradiation) are shown in Figure 6 and the relevant parameters are summarized in Table 3.

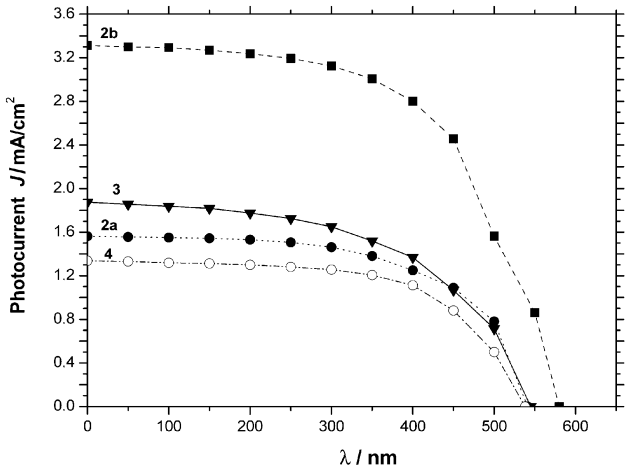

Figure 6. Photocurrent density–photovoltage characteristics of DSSCs using the $Ru^{II}$ dyes **2a** (---●---), **2b** (---■---), **3** (—◀—) and **4** (---○---) under AM 1.5 simulated light.

Under standard global AM 1.5 illumination conditions, solar cells of dye **2b** gave a short-circuit photocurrent density ($J_{sc}$) of 3.32 mA cm$^2$, 580 mV open circuit potential ($V_{oc}$), and 0.58 fill factor (*ff*) yielding an overall power conversion efficiency ($\eta$) of 1.12%. Under similar experimental conditions, the **2a** dye produces lower (1.56 mA cm$^2$) short-circuit current density and open circuit potential of 541 mV, respectively. The open-circuit voltage of **2b** is similar to that of the **N719** dye and by 8% larger than that of **2a**, probably due to the suppression of the dark current.[2a,42] On the other hand, the short-circuit photocurrent density and open circuit voltage of the cells with the cyano complex **4** slightly decrease compared to the precursor **2a**. The observed photovoltaic parameters $J_{sc}$, $V_{oc}$, and *ff* (see Table 3) for complex **4** are significantly higher than those of the corresponding *cis*-[Ru(dcbpyH$_2$)(CN)$_2$] sensitizer (1.06 mA cm$^2$, 310 mV, and 0.24, respectively).[43] Finally, the value of the fill factor (*ff*) is not affected by the nature of the dye, while the overall conversion efficiency is in the 0.5% range for sensitizers **2a**, **3**, and **4**, respectively. It has to be pointed out that in complex **4**, coordination to the $Ti^{4+}$ center on the $TiO_2$ surface could occur via the lone pair of electrons on the nitrogen of the –CN functional group.[44] In addition, the two deprotonated carboxylate (–$COO^-$) groups of the complex, appear to be anchored on the semiconductor surface via bidentate or bridging coordination as previously demonstrated for the **N712** dye.[22]

These data clearly indicate that the performance characteristics of complex **2b**, with fully protonated carboxylate groups of the dcbpyH$_2$ ligand, are superior to those of the dyes **2a**–**4**, while the **N719**-sensitized solar cell gave the best overall efficiency. This is further supported by the cyclic voltammetry results. Also the better performance may be attributed to the higher number of protons carried by the sensitizer, something which is in accord with the reports

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

mentioned for carboxylated $Ru^{II}$ phenanthroline complexes.[45] In fact, complex **2b** contains one more proton compared to **2a** and **3**, and two additional protons from the sensitizer **4**. In addition, the corresponding solid-state solar cell using the dye **2b** shows similar overall energy conversion efficiency ($\eta$) compared to that of the methylated derivative [Ru(bdmpp)(dcbpyH$_2$)Cl](PF$_6$).[13b] Further studies are in progress to improve the photovoltaic characteristics of the dye-sensitized solar cell based on heteroleptic complexes including bpp ligands.

## Conclusions

Halide substitution reactions of the [Ru(bpp)(dcbpyH)Cl] precursor **2a** with various nucleophiles ($NCS^-$, $CN^-$) led straightforwardly to the neutral and anionic sensitizers [Ru(bpp)(dcbpyH)(NCS)] (**3**) and (Na)[Ru(bpp)(dcbpy)(CN)] (**4**), respectively. Also reaction of **2a** with the electrophile (HCl) gave quantitatively the cationic [Ru(bpp)(dcbpyH$_2$)Cl]Cl complex. Following simple purification techniques the isolated dyes are analytically pure and used as such for solar cell applications. All new heteroleptic $Ru^{II}$ compounds have been anchored to nanocrystalline $TiO_2$-film electrodes using a solid-state electrolyte, namely PEO/$TiO_2$/$I^-$/$I_3^-$, and the photovoltaic properties of the resulting dye-sensitized solar cells have been characterized and compared with the properties of the one prepared with *cis*-[Ru(dcbpyH)$_2$(NCS)$_2$](NBu$_4$)$_2$ (**N719**). The photovoltaic performance of nanocrystalline $TiO_2$ solar cells sensitized by the complexes **2**–**4** bearing the 2,6-bis(1-pyrazolyl)pyridine and bipyridinedicarboxylic acid depends remarkably on the number of carboxyl functional groups. Thus, the [Ru(bpp)(dcbpyH$_2$)Cl]Cl dye **2b** (with two carboxyl anchoring groups), yields under standard AM 1.5 illumination a 1.12% power conversion efficiency that is about two-times higher than that of the solar cells sensitized with the dyes **2a** and **3** (bearing one carboxy group) and of complex **4** (without any carboxy group). However, dye **2b** is almost 40% less efficient than the **N719**-sensitized solar cell. As expected, the photovoltaic performance of the Ru–NCS dye **3** was higher than that of the Ru–Cl precursor **2a**, and this can be attributed to a better tuning and stabilization of the $t_{2g}$ orbitals of the thiocyanate complex.[13a] We are currently examining the photovoltaic characteristics of all the above dyes in semi-solid propylene carbonate-based modified nanocomposite redox electrolytes prepared in our group. This is expected to lead to cell optimization and a further efficiency increase of the corresponding DSSCs.

## Experimental Section

**General Procedures and Materials:** All manipulations (unless otherwise noted) were carried out under Ar using standard Schlenk techniques. $RuCl_3 \cdot 3H_2O$ and the solvents were used without further purification. The ligand 2,6-bis(1-pyrazolyl)pyridine was prepared according to literature methods.[11] The solvents used were thoroughly degassed by argon passage for 20 min before use. Elemental analyses were obtained from the Central Analytical Group of the Chemistry Department of the Humboldt-Universität zu Berlin. The C, H, N analyses of all compounds were carried out twice on a Leco CHNS-932 elemental analyzer. The mean C, H, N values of each compound are given below. Chlorine was determined using Schöniger's method followed by titration with $Hg(ClO_4)_2$.[46] Melting or decomposition points were determined with a Büchi SMP 530 melting point apparatus (Dr. Tottoli, patent 320338) and were not corrected. The samples were sealed in capillary tubes and heated slowly until the compounds melted or decomposed. Infrared spectra were measured with a Nicolet 550 Magna-IR™ spectrometer as KBr pellets in the region of 4000–400 $cm^{-1}$. The following abbreviations were used for the intensities of the IR absorption bands: vs. = very strong, s = strong, m = medium, w = weak, sh = shoulder. The solid-state RAMAN spectra were recorded in a frequency range of 3700–3 $cm^{-1}$ (Bruker Vertex 70/RAM II) with an excitation wavelength of 1064 nm, at ambient and low temperature (140 K) applying a laser power of 4–250 mW on the sample. Spectra were an average of 64 or 1024 scans collected at 4 $cm^{-1}$ resolution. Absorption spectra were recorded with a Perkin–Elmer Lambda 19 UV/Vis spectrometer and emission spectra were recorded with a Photon Technology International QM-1 steady-state spectrometer of the School of Chemistry, University of Birmingham. $^1H$ NMR spectra were measured with a Bruker Avance 500 MHz or a Bruker AM-300 spectrometer in $(CD_3)_2SO$ at the NCSR Demokritos and the Chemistry Department of the Humboldt-Universität zu Berlin. The spectra were calibrated against the residual proton resonances of the deuterated solvent ([D$_6$]DMSO, $\delta_H$ = 2.49 ppm). Electrospray mass spectra ESMS-TOF (TOF = time of flight) and ESMS were performed at the Mass Spectrometry Service Centre of the School of Chemistry, University of Birmingham and at the Mass Spectrometry and Dioxin Analysis Lab. IRRP of the National Centre for Scientific Research "Demokritos". Cyclic voltammetry measurements were performed in ca. $10^{-3}$ M aqueous solutions of the corresponding complexes containing 0.1 M $NBu_4ClO_4$ as supporting electrolyte, at a sweep rate of 100 mV $s^{-1}$, using a PAR Model 174 A polarographic analyzer operating in conjunction with a 33120 A Hewlett–Packard function–arbitrary waveform generator. A three-electrode three-compartment electrochemical cell was used, with Metrohm dot (6.0302.000) and planar (6.0305.000) platinum working and counter electrodes, respectively, as well as a Metrohm Ag/AgCl 6.0726.100 reference electrode. The experiments were performed in deoxygenated solutions purified by Ar gas (99.9%) for 30 min prior to use. During the experiment the Ar was passed over the solution surface.

**Crystal Structure Determination of 4·7.5H$_2$O·0.5CH$_3$CN, and 5·2CH$_3$CN·0.5CH$_3$OH:** Orange prismatic crystals of **4**·7.5H$_2$O·0.5CH$_3$CN were obtained upon slow diffusion of an acetone/acetonitrile mixture (20 mL, 10:1, v/v) into an aqueous solution (3–4 mL) of complex **4** at ambient temperature. Brown prismatic crystals of **5**·2CH$_3$CN·0.5CH$_3$OH were grown upon slow diffusion of diethylether into a solution of **5** in an acetonitrile/acetone mixture (4:1, v/v) at room temperature. Diffraction measurements were taken with a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo-$K_\alpha$ radiation. Important crystal data and parameters for data collection are reported in Table 4. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11° < 2\theta \leq 23°$. Three standard reflections monitored every 97 reflections showed less than 3% intensity fluctuation and no decay. Lorentz, polarization and psi-scan absorption corrections (for **5** only) were applied using Crystal Logic software. The structures were solved by direct methods using SHELXS-86[47] and refined

by full-matrix least-squares techniques on $F^2$ with SHELXL-97.[48] Further experimental crystallographic details for **4**: $2\theta_{max}$ = 50°, scan speed 5.0° min; scan range 1.6 +$\alpha_1\alpha_2$ separation; reflections collected/unique/used, 6071/5796 [$R_{int}$ = 0.0073]/5796; 502 parameters refined; $(\Delta/\sigma)_{max}$ = 0.009; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.927/–0.356 e Å$^3$; $R/R_w$ (for all data), 0.0500/0.1402. The asymmetric unit in the cell of **4** contains 7.5 molecules of water and 0.5 molecules of acetonitrile. One of the water solvate molecules [Ow(8)] as well as the MeCN were refined with occupation factors fixed to 0.50. Hydrogen atoms were located by difference maps and were refined isotropically. No H-atoms for the solvate molecules were included in the refinement. All non-H atoms were refined anisotropically. Further experimental crystallographic details for **5**: $2\theta_{max}$ = 45.5°, scan speed 1.2° min; scan range 2.2 +$\alpha_1\alpha_2$ separation; reflections collected/unique/used, 5878/5541 [$R_{int}$ = 0.1096]/5541; 486 parameters refined; $(\Delta/\sigma)_{max}$ = 0.000; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.937/–0.308 e Å$^3$; $R/R_w$ (for all data) = 0.1189/0.2352. Hydrogen atoms were introduced at calculated positions as riding on bonded atoms; except those of the solvate molecules, which were not included in the refinement. All non-H atoms were refined anisotropically. The second acetonitrile solvate molecule was refined isotropically, the methanol solvate was refined isotropically with the occupation factor fixed to 0.50.

**$TiO_2$ Electrode Preparation:** Nanoporous $TiO_2$ thin films (15 μm thick) on conducting glass substrates TEC 8 (purchased from Hartford Glass Co. Inc.) using the doctor blade technique were prepared, as previously reported.[49] An adhesive tape strip on the conductive glass determines the film thickness. These films were sintered in air at 450 °C at a rate of 20 °C min$^{-1}$ for 30 min and were stored in a vacuum desiccator in the dark until required for use. The titania films were sensitized at ambient temperature for 12–15 h by immersing them into a c.a. $3 \times 10^{-4}$ M solution of the complexes in dimethyl sulfoxide. Immersion of nanocrystalline titania films in the solution of the dyes resulted in strong coloration of the films (in the case of complex **4** a faint yellow coloration was observed). The dye-coated electrodes were taken out of the solution, washed thoroughly with dimethyl sulfoxide and ethanol to remove any loosely adsorbed dye, shortly dried under a stream of dry argon and used as such for photovoltaic measurements. The sensitized $TiO_2$ thin films were incorporated in a sandwich-type solar cell employing a solid composite electrolyte ($PEO/TiO_2/I^-/I_3^-$)[14] and using a platinized TEC 8 counter electrode. An adhesive tape was placed between the electrodes to avoid short-circuiting, and the two electrodes were firmly pressed. A more detailed fabrication procedure for the nanocrystalline titania electrodes, the cell assembly, and the photo-electrochemical characterization has been described elsewhere.[50] The working electrode had an illuminated surface of 0.16 cm$^2$. Photovoltaic data were measured using a 300-W Xenon lamp that was focused to give 1000 W m$^2$, the equivalent of one sun at AM 1.5, at the surface of the test cell.

**Synthesis of [Ru(bpp)$Cl_3$] (1):** A Schlenk tube was charged with 0.165 g (0.63 mmol) of $RuCl_3 \cdot 3H_2O$ and 0.106 g (0.502 mmol) of the bpp ligand and the mixture was degassed by applying fine vacuum for 0.5 h. EtOH (20 mL) was then added to the mixture via a double-ended needle, and the brown suspension was heated to a gentle reflux for 3 h. The resulting red-brown suspension was cooled to ambient temperature and left to settle overnight at 5 °C. The solid precipitated was filtered in air washed with EtOH ($3 \times 20$ mL) and $Et_2O$ ($2 \times 10$ mL) and dried in vacuo over $P_2O_5$ to give complex **1** as a dark red-brown solid; yield 0.21 g (85.2%). **1·4$H_2O$** $C_{11}H_{17}Cl_3N_5O_4Ru$ (490.72): calcd. C 26.92, H 3.49, N 14.27; found C 26.73, H 3.24, N 13.82. IR (KBr): $\tilde{\nu}$ = 3159 (w, C–H, aromatic), 3124 (w, C–H, aromatic), 3090 (m, C–H, aromatic), 3049 (m, C–H, aromatic), 1576 (w), 1529 (m), 1483 (s), 1433 (w), 1408 (w), 1369 (w), 1346 (s), 1317 (w), 1256 (w), 1194 (w), 1175 (w), 1051 (m), 961 (m), 907 (w), 802 (s), 781 (s, sh), 773 (s, sh), 690 (w), 594 (w), 457 [br. (m)] cm$^{-1}$.

**Synthesis of [Ru(bpp)(dcbpyH)Cl] (2a):** Under a slow stream of argon a Schlenk tube was charged with complex (**1**) (0.196 g, 0.399 mmol) and a slight excess of the ligand $dcbpyH_2$ (0.114 g, 0.468 mmol) in an EtOH/$H_2O$ mixture (30 mL, 1:1, v/v) giving a dark brown suspension. LiCl (25 mg, 0.59 mmol) in an EtOH/$H_2O$ mixture (10 mL, 1:1, v/v) and $Et_3N$ (0.11 mL, 0.788 mmol) were added affording instantly a green solution that gradually turned to orange-brown upon heating to a gentle reflux for 7 h. While hot the suspension was filtered (in air) through a pad of Celite. The resulting clear orange-brown solution was concentrated to a few milliliters and was stored for 2 d at 5 °C. The solid precipitated was filtered, washed with small amounts of cold water, $Et_2O$ (15 mL), dried in air and finally in vacuo in a desiccator over $P_2O_5$. A further crop was obtained from the filtrate upon concentration and storage at 5 °C. This procedure was repeated twice in order to obtain complex **2a** analytically pure as a red-brown microcrystalline solid; yield 0.243 g (97.1%), m.p. >215 °C. **2a·2$H_2O$**, $C_{23}H_{20}ClN_7O_6Ru$ (626.98): calcd. C 44.06, H 3.22, Cl 5.65, N 15.64; found C 43.90, H 2.96, Cl 5.75, N 15.69. IR (KBr): $\tilde{\nu}$ = 3112 (w, C–H, aromatic), 3089 (m, C–H, aromatic), 3035 (w, C–H, aromatic), 2924 (w, C–H, aliphatic), 1718 [m, ν(C=O)], 1628 [m, $\nu_{as}(CO_2^-)$], 1609 [s, ν(C=C)], 1573 (w), 1539 [m, ν(C=C)], 1521 (w), 1482 [vs, ν(C=N)], 1408 (s), 1369 [m, $\nu_s(CO_2^-)$], 1340 (m), 1306 (w), 1265 (m), 1237 [m, ν(C–O)], 1174 (w), 1129 (w), 1072 (w), 1049 (m), 1025 (m), 955 (m), 901 (m), 774 (s), 717 (w), 684 (m), 595 (w), 528 (w), 445 (m) cm$^{-1}$. **Synthesis of [Ru(bpp)(dcbpyH$_2$)Cl]Cl (2b):** 0.25 mL (0.5 mmol) of an aqueous HCl solution (2 M) was added whilst stirring to a suspension of complex (**2a**) (30 mg, 0.051 mmol) in MeOH (10 mL). Immediately, the solid dissolved and the resulting dark red-brown solution was stirred at ambient temperature for 2 h. The volume of the solution was concentrated to some milliliters, and the product was precipitated with diethyl ether (excess). The resulting brown-black solid was washed with $Et_2O$ (2 × 10 mL) and dried in an oven at 50 °C over 2 h; yield quantitative, m.p. >240 °C. **2b·4H$_2$O**, $C_{23}H_{25}Cl_2N_7O_8Ru$ (699.46): calcd. **Synthesis of Na[Ru(bpp)(dcbpy)(CN)] (4):** Under argon a solution of NaCN (0.031 g, 0.63 mmol) in water (5 mL) was added to a solution of complex **2a** (0.034 g, 0.054 mmol) in $H_2O$/MeOH (1:2, v/v) (15 mL). The orange-brown solution was heated to a gentle reflux for 5 h leading to a clear orange solution that was concentrated to approximately 4–5 mL. Upon addition of acetone (20 mL) an orange solid was precipitated. The latter was filtered off, washed with acetone (2 × 10 mL) and $Et_2O$ (2 × 10 mL) and dried in air as well as in an oven at 70 °C for 0.5 h. X-ray equality orange single crystals of **4**·7.5H$_2$O·0.5CH$_3$CN were obtained upon slow evaporation of a mixture of acetone/acetonitrile (20 mL, 10:1, v/v) into a solution of the product in water. The orange crystals were collected on a filter paper, washed with small amounts of $Et_2O$ (2 × 5 mL) and dried in an oven at 70 °C for 2 h to obtain 22 mg of complex **4**; yield 67.5%, m.p. 249 °C (dec.). **4·6H$_2$O**, $C_{24}H_{27}NaN_8O_{10}Ru$ (711.58): calcd. CCDC-639397 (for **4**·7.5H$_2$O·0.5CH$_3$CN) and -639398 (for **5**·2CH$_3$CN·0.5CH$_3$OH) contain supplementary crystallographic data. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

## Acknowledgments

This work has been partially supported by the British Council (Greek-British 2004–2006 bilateral cooperation project), the GSRT Greece (PENED 03EΔ118 project) and the European Union (STREP 033313 project). The authors express their gratitude to Prof. Dr. A. C. Filippou for access to the Central Analytical Group of the Chemistry Department of the Humboldt-Universität zu Berlin and the University of Bonn. Furthermore, we acknowledge Reader Z. Pikramenou and Research Director Dr. L. Leodiadis for access to the Mass Spectrometry Service Centre of the School of Chemistry, University of Birmingham and the Mass Spectrometry and Dioxin Analysis Lab. IRRP of the National Centre for Scientific Research "Demokritos", respectively. Finally, helpful assistance from Dr. G. Pistolis, Dr. E. Chatzivasiloglou, Dr. M. Chatzichristidi, N. Weidemann, G. Konti, and N. Alexaki is highly acknowledged.

[17] Similarly the addition of an excess of aqueous HCl (2 M) to **3** and **4** yields the desired products [Ru(bpp)(dcbpyH$_2$)(NCS)]Cl and [Ru(bpp)(dcbpyH$_2$)(CN)]Cl, respectively, together with other unidentified species, as evidenced by IR and $^1$H NMR spectroscopy. Work is in progress to elucidate the experimental conditions in order to avoid the formation of the side products.

[18] In the case of the previously reported [Ru(bdmpp)(NCS)(dcbpyH$_2$)](PF$_6$) complex, the $\nu_{as}$(NCS) band in the IR spectrum is not so strong. It appears as a shoulder indicating probably that the NCS ligand is coordinated via the sulfur atom as well. Preliminary photo-electrochemical experiments with the crystallized sample containing only the N-isomer showed an improved power conversion efficiency of $\eta$ = 1.86% (instead of 1.70%).

# [Bis(guanidine)]zinc Complexes and Their Application in Lactide Polymerisation

**Janna Börner,[a] Sonja Herres-Pawlis,*[a] Ulrich Flörke,[a] and Klaus Huber[b]**

**Keywords:** Guanidine / D,L-Lactide / N ligands / Ring-opening polymerization / Zinc

The bis(guanidine)-stabilised zinc complexes [$N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine]dichloridozinc(II), [Zn(DMEG$_2$e)Cl$_2$] (**C1**), diacetato[$N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine]zinc(II), [Zn(DMEG$_2$e)(CH$_3$COO)$_2$] (**C2**), and bis[$N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine]zinc(II) bis(trifluoromethanesulfonate), [Zn(DMEG$_2$e)$_2$](CF$_3$SO$_3$)$_2$ (**C3**), have been synthesised and completely characterised by means of X-ray structure analysis, NMR spectroscopy and mass spectrometry. These [bis(guanidine)]zinc complexes were investigated regarding their activity in the bulk polymerisation of D,L-lactide. It could be shown that these compounds are able to act as initiators for lactide polymerisation, and polylactides with molecular weights ($M_w$) of around 18000–59000 g/mol could be obtained. Variation of the reaction temperature revealed that the molecular weights decrease with increasing temperature. Additionally, the correlation of the intrinsic viscosity with the molecular weight demonstrates that the obtained polymers are linear and structurally homogeneous.

## Introduction

The increasing shortage of resources has enforced the search for production techniques for biodegradable polymers made of renewable raw materials. An example is polylactide (PLA), an aliphatic polyester, which can be obtained by the ring-opening polymerisation (ROP) of cyclic esters like lactide. The monomer for PLA production is available from renewable raw materials like corn or sugar beets by a bacterial fermentation process. The polylactide that is obtained by metal-catalysed ROP can be either recycled or composted after use, and therefore it is $CO_2$-emission-neutral. Also, its unique physical properties qualify PLA to be a viable alternative to petrochemical-based plastics. Combined with its biocompatibility and its ability to degrade both in vivo and in vitro, PLA has a great range of potential applications ranging from widespread use, including coatings, fibres, films and packages, to use in specialised medical and pharmaceutical fields.[1]

Until now, the ROP of lactide could not be accomplished economically, and therefore PLA has only been used in biomedical applications.[2] To change the polymer from a speciality material to a large-volume commodity plastic,[3] the development of new polymerisation catalysts is required. Most large-scale processes are based on the use of stannous compounds as initiators.[4] However, for use in food packaging or similar applications, heavy metals are undesirable because of accumulation effects.[5] Particularly suitable for this purpose in order to substitute heavy-metal-based catalyst systems are zinc complexes with N-donor-functionalised ligands because they are mostly colourless, inexpensive and nontoxic.[6]

Examples of (guanidine)zinc complexes have already been reported.[7] It could be shown that some of these possess catalytic activity, which makes guanidines a very promising ligand class leading to catalytically active zinc complexes.[8] Bis(guanidines) offer excellent donor properties that allow the coordination of metal ions and enable the access of substrate molecules to the metal centre at the same time. A great advantage of bis(guanidines) is their modular synthesis protocol, which combines different spacer and guanidine groups and thus admits a flexible ligand design.[9] The variation of the ligands allows an optimal adaptation to actual demands. Moreover, the guanidine ligands are strongly related to the essential and ubiquitous amino acid arginine, which is nontoxic.[10]

Herein we report on the synthesis and characterisation of the first zinc complexes including $N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine (DMEG$_2$e, **L1**)[11] as bis(guanidine) ligand, which are actually the first examples of aliphatic bis(guanidine)-stabilised zinc complexes. The complexes [$N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)-ethane-1,2-diamine]dichloridozinc(II), [Zn(DMEG$_2$e)Cl$_2$] (**C1**), diacetato[$N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)-ethane-1,2-diamine]zinc(II), [Zn(DMEG$_2$e)(CH$_3$COO)$_2$] (**C2**), and bis[$N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)ethane-

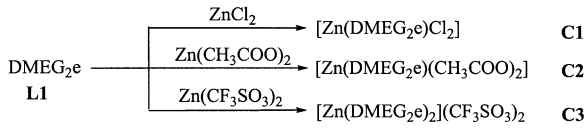
1,2-diamine]zinc(II) bis(trifluoromethanesulfonate), [Zn(DMEG$_2$e)$_2$](CF$_3$SO$_3$)$_2$ (**C3**), were investigated regarding their activity in the bulk polymerisation of D,L-lactide. Our results prove that the bis(guanidine) complexes possess catalytic activity in the ROP of D,L-lactide. PLAs with molecular weights ($M_w$) of around 18000–59000 g/mol could be obtained.

## Results and Discussion

The bis(guanidine) ligand $N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine (DMEG$_2$e, **L1**) was synthesised by condensation of the Vilsmeier salt *N*,*N*′-dimethyl-*N*,*N*′-ethylenechloroformamidinium chloride with ethylenediamine, as previously reported.[11] In the reaction of **L1** with ZnCl$_2$ in MeCN, colourless crystals of [Zn(DMEG$_2$e)Cl$_2$] (**C1**) could be obtained in 98% yield. The reaction of **L1** with Zn(CH$_3$COO)$_2$ and Zn(CF$_3$SO$_3$)$_2$ in THF leads to the formation of colourless crystals of [Zn(DMEG$_2$e)(CH$_3$COO)$_2$] (**C2**) in 97% yield and [Zn(DMEG$_2$e)$_2$](CF$_3$SO$_3$)$_2$ (**C3**) in 73% yield, respectively (Scheme 1). The described guanidine-stabilised zinc complexes formed independently of the molar ratio of the starting materials.



Scheme 1. Schematic synthesis of **C1**–**C3**.

The molecular structures of compounds **C1**–**C3** (Figures 1, 2 and 3), determined by X-ray crystallography at 120 K, reveal that each Zn$^{II}$ atom is fourfold coordinated. In **C1** and **C2**, two coordination sites are occupied in a chelating manner by the N-donor atoms of DMEG$_2$e, forming a five-membered heterocycle that adopts a half-chair conformation, whereas in **C3**, four coordination sites are occupied analogously by the N-donor atoms of two DMEG$_2$e molecules. In **C1** and **C2**, the remaining coordination sites are occupied by chloride ions [Zn–Cl distance: 2.260(1) Å] or acetate ions [average of the Zn–O distances: 1.963(2) Å]. The distances between the zinc ion and the N-donor atoms decrease, going from **C1** [2.038(2) Å] over **C2** [av. 2.025(2) Å] to **C3** [av. 2.012(4) Å], while the length of the C=N bonds of the guanidine residues are identical in all three compounds [av. **C1**: 1.309(3); **C2**: 1.307(2); **C3**: 1.309(5) Å]. The zinc atoms in **C1** and **C2** are coordinated in a distorted tetrahedral manner. The sums of the angles at the Zn atom are 656.18° for **C1** and 659.48° for **C2** and therefore fit well with the value for a perfect tetrahedral geometry (656.82°). However, the bite angle of 86.18(10)° (**C1**) and 86.16(6)° (**C2**) is too small for a perfect tetrahedral geometry, resulting in a distortion. This distortion is reflected in the values of the angles between the ZnCl$_2$ and the ZnN$_2$ plane (74.5°) and the ZnO$_2$ and the ZnN$_2$ plane (76.3°), which is 90° in a tetrahedron. In contrast, the environment of the Zn atom in **C3** lies between tetrahedral and square-planar coordination. The sum of the angles at the Zn atom is 670.41° and lies between the values for a tetrahedron (656.82°) and a square-planar coordination (720°), indicating more tetrahedral character. The bite angles of both DMEG$_2$e ligands are identical [85.5(1) and 85.2(1)°]. The bite angles defined by the ligands are significantly smaller than the tetrahedron angle (109.47°) and therefore lead to a distortion of the tetrahedral structure in the direction of square-planar coordination. This is also shown in the value of the angle between the ZnN$_2$ planes (53.9°), which is between the tetrahedral (90°) and the square-planar coordination (0°). Furthermore, the distorted structure favours the minimisation of the interactions between the sterically demanding guanidine residues. The twist within the guanidine heterocycle, which minimises the ecliptic interactions of the ring-bound hydrogen atoms, is limited in the DMEG$_2$e systems by the rigid ethylene bridge between the two amine functions. The values of

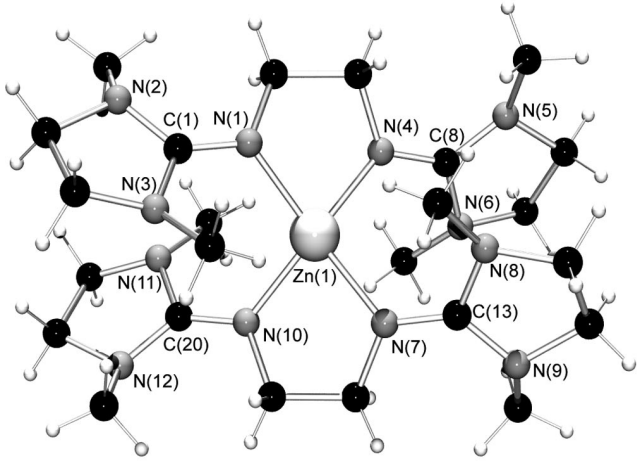

Figure 3. Molecular structure of $[Zn(DMEG_2e)_2]^{2+}$ in crystals of $[Zn(DMEG_2e)_2](CF_3SO_3)_2$ (**C3**) as determined at 120 K. Selected bond lengths [Å] and angles [°]: Zn(1)–N(1) 2.028(3), Zn(1)–N(7) 2.021(3), Zn(1)–N(10) 2.004(3), Zn(1)–N(4) 1.996(3), N(1)–C(1) 1.303(5), N(4)–C(8) 1.307(5), N(7)–C(13) 1.315(5), N(10)–C(20) 1.311(5); N(4)–Zn(1)–N(10) 145.3(1), N(4)–Zn(1)–N(7) 106.0(1), N(10)–Zn(1)–N(7) 85.5(1), N(4)–Zn(1)–N(1) 85.2(1), N(10)–Zn(1)–N(1) 105.3(1), N(7)–Zn(1)–N(1) 143.1(1).

the angles between the $C_{gua}N_3$ and the $NC_3$ plane are thus slightly smaller (**C1**: 15.5°; **C2**: 14.9°; **C3**: 15.6°) than those reported for a similar DMEG-containing system (17.4°).[9a]

The comparison of $[Zn(DMEG_2e)_2](CF_3SO_3)_2$ (**C3**) with its copper and iron analogues $[Cu(DMEG_2e)_2][Cu_2I_4]$[11] (**C4**) and $[Fe(DMEG_2e)_2][Fe_2(CO)_8]$[11] (**C5**) shows a great similarity of all three complex cations. The metal atoms in the $[M(DMEG_2e)_2]^{2+}$ unit are present in the oxidation state +2 and are coordinated by four ethylene-bridged imine nitrogen atoms of the bis(guanidine) ligands in a strongly distorted tetrahedron. The five-membered chelate heterocycles adopt a half-chair conformation. The angles between the $MN_2$ planes (**C3**: 53.9°; **C4**: 44.5°; **C5**: 48.7°) show that the coordination mode remains in the intermediate position between the tetrahedral (90°) and the square-planar coordination (0°). The averaged bite angles of the complexes do not differ considerably [**C3**: 85.4(1)°; **C4**: 84.4(1)°; **C5**: 83.5(1)°] and also the averaged distances of the C=N bonds [**C3**: 1.309(5) Å; **C4**: 1.302(4) Å; **C5**: 1.307(3) Å] are identical. The values of the metal–nitrogen bonds [**C3**: 2.012(3) Å; **C4**: 1.970(2) Å; **C5**: 2.044(2) Å] are, despite the different metal ions and their varying ion radii, in a similar range.

As mentioned before, guanidines are a very promising ligand class leading to catalytically active zinc complexes. Therefore, the obtained complexes **C1**–**C3** were investigated regarding their activity in the bulk polymerisation of D,L-lactide. For this purpose D,L-lactide and the initiator (*I*/*M* ratio 1:500 or 1:1000) were tempered at 135 °C, 150 °C and 165 °C. After a reaction time of 24 or 48 h, the polymer melt was dissolved in dichloromethane, and then the polylactide was precipitated in cold methanol. We could prove that all three bis(guanidine) complexes possess catalytic activity in the ROP of D,L-lactide. A great advantage of the described zinc compounds is their stability towards air and moisture because they can be handled exposed to air without loss of activity. Complexes **C1** and **C3** are stable on air for months, while **C2** is hygroscopic but stable on air for hours. In order to specify the catalytic activity of the complexes, the monomer conversion was defined, and the molecular weights of the obtained polylactide were determined by gel permeation chromatography (see Table 1).

In general, the monomer conversion as well as the weight-averaged molar mass values ($M_w$) of the corresponding polymer are higher for **C1** than for **C2** and **C3**. At the standard temperature for lactide polymerisations, which is 150 °C,[5] **C3** shows the best results for $M_w$ (32000–38000 g/mol) and the best yields. The acetate complex **C2** exhibits a weaker performance. This indicates the effect of the anionic component of the zinc salt on the catalytic activity of the corresponding zinc complex. Interestingly, an increase of the reaction time from 24 to 48 h does not improve the conversion, nor does it increase the molecular weight of the obtained polymer. On the contrary, a decrease of conversion and molecular weight

Table 1. Polymerisation of D,L-lactide initiated by **C1**–**C3**.

can be observed. Similar observations were reported by Chisholm et al. and Schwach et al.,[12] who considered side reactions like the interchain or intrachain transesterification as well as the chain-transfer reaction to be responsible for this effect. In this context, it is expected that a decrease of reaction temperature would lead to minor side reaction effects.[12] Our results (see Figure 4) support this hypothesis. At 135 °C, **C1** and **C2** lead to considerably larger polymers than at higher temperatures, with $M_w$ values up to 59000 g/mol. Thus, molecular weights achieved by the present procedure decreased with increasing temperature. Only in the case of **C3** is this temperature effect not pronounced, because a maximum for the degree of polymerisation is reached at 150 °C.

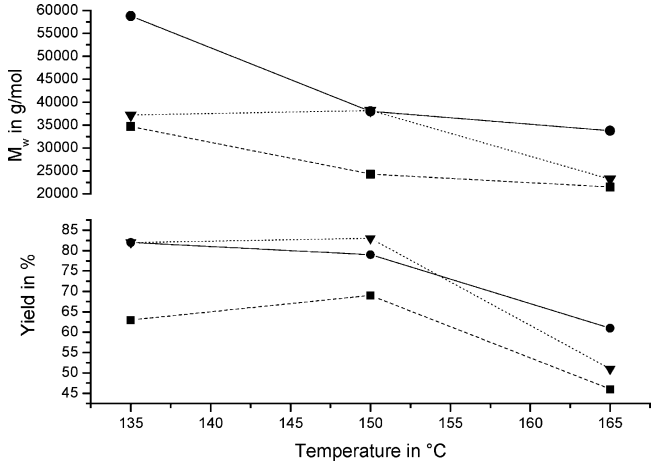

Figure 4. Dependence of weight-averaged molar mass ($M_w$) and yield vs. reaction temperature for the three initiator systems **C1**–**C3** (straight line: **C1**; dashed line: **C2**; dotted line: **C3**).

In order to study the structural characteristics of the synthesised polymers, the intrinsic viscosities were correlated with the molecular weight $M$ of the polymers. As outlined in Figure 5, all polymer samples exhibited a unique trend. For polymers large enough, this correlation is described by the Mark–Houwink equation (see Figure 5):[13] $[\eta] = K \cdot M^{\alpha}$.

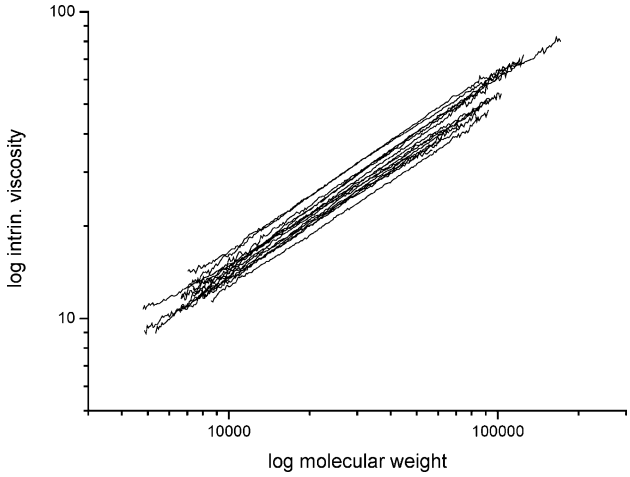

Figure 5. Mark–Houwink plot of all obtained PLAs. The calculated mean value for $\alpha$ is 0.59 and for $K$ is 0.068 at 35 °C in THF.

The linear behaviour and unique trend of all examined polymers indicates that the obtained PLA samples are structurally homogeneous and linear. Hence, the structure of the polymer reported herein is independent of the initiator used and the averaged values for the Mark–Houwink constants at 35 °C in THF were calculated to be $\alpha = 0.59$ and $K = 0.068$. Further values for different temperatures and solvents were reported by Rafler et al.[14] and Schindler and Harper.[15]

In order to classify the polymerisation activity of the (guanidine)zinc systems, a comparison of catalyst systems reported in the literature is summarised in Table 2. This comparison reveals that our systems do not achieve the highest molecular mass values, but compared to Entries 1 and 2 the chosen $M/I$ ratios are more favourable. Furthermore, the reaction times for polymerisations initiated by **C1**–**C3** are acceptable for the industrial standard. Compared to the highly active systems (Entries 4, 5, 8), **C1**–**C3** yielded similar or even higher molecular masses. The catalyst in Entry 7 is fast at ambient temperature and yields PLAs with high molecular masses, but the zinc alkoxide complexes are only stable under

exclusion of moisture and air. Hence, the (guanidine)zinc complexes combine several factors that are necessary requirements for an efficient catalyst. These systems can be handled in air and give polymers with molecular masses that allow the application in industrial production processes. To increase the activity of the (guanidine)zinc catalysts, the reaction conditions have to be further optimised. The structural influences of the guanidine ligand on the activity of the zinc complexes in lactide polymerisation are being studied at the moment.

## Conclusions

In this contribution we reported on the synthesis and complete characterisation of the first examples of aliphatic bis(guanidine)-stabilised zinc complexes that were proven to be active initiators in the ring-opening polymerisation of D,L-lactide. PLAs with molecular weights ($M_w$) of around 18000–59000 g/mol could be obtained. In complexes with the same ligand the activity of the initiator depends on the anionic component of the zinc salt. We found that complexes with zinc bis(triflate) and zinc dichloride seem to be the most auspicious candidates for application in the ROP of lactide. By changing the reaction temperature it could be shown that lower temperatures allow side reactions to be avoided during the polymerisation and thus give higher molecular masses. Moreover, the Mark–Houwink correlation demonstrates that the obtained polymers are linear and homogeneous. Compared to other systems the (guanidine)zinc complexes possess an advantageous combination of properties: they are nontoxic, comparably stable and give PLAs with good $M_w$ values at industrial conditions. This makes the (guanidine)zinc systems a promising class of catalysts for the ring-opening polymerisation of D,L-lactide. The reaction control and the clarification of the reaction mechanism as well as the synthesis of more active (guanidine)zinc complexes for the ROP of lactide are topics of current research.

## Experimental Section

**Materials and Methods:** All manipulations were performed under nitrogen (99.996%) dried with $P_4O_{10}$ granulate using Schlenk techniques. Solvents were purified according to literature procedures and also kept under nitrogen. Zinc dichloride (99.99%, Acros), zinc diacetate (99.99%, Acros), zinc bis(trifluoromethanesulfonate) (98%, Aldrich) and D,L-lactide (3,6-dimethyl-1,4-dioxane-2,5-dione, Aldrich) were used as purchased. The $N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine (**L1**) was prepared according to a literature procedure.[11]

**Physical Measurements:** NMR: Bruker Avance 500. The NMR signals were calibrated to the residual signals of the deuterated solvents ($CDCl_3$: $\delta_H$ = 7.26 ppm; $CH_3CN$: $\delta_H$ = 1.94 ppm). IR: Nicolet P510. MS (EI, 70 eV): Finnigan MAT 40. Elemental analyses: Perkin–Elmer analyser Model 2400.

**Crystal Structure Analyses:** Crystal data for compounds **C1**, **C2** and **C3** are presented in Table 3. X-ray diffraction data were collected with a Bruker-AXS SMART APEX CCD, using Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å) and a graphite monochromator. SAINT and SADABS were used for data reduction and absorption correction.[24] The structures were solved by direct and conventional Fourier methods, and all non-hydrogen atoms were refined anisotropically with full-matrix least squares based on $F^2$ (SHELXTL[24]). Hydrogen atoms were derived from difference Fourier maps and placed at idealised positions, riding on their parent C atoms, with isotropic displacement parameters $U_{iso}(H) = 1.2U_{eq}(C)$ and $1.5U_{eq}$(C methyl). All methyl groups were allowed to rotate but not to tip. CCDC-652328 (for **C1**), -652329 (for **C2**) and -652330 (for **C3**) contain the supplementary crystallographic data (excluding structure factors) for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Gel Permeation Chromatography:** The GPC measurements were accomplished with a Waters GPC 2000 instrument equipped with a precolumn (10 μm) and a combination of three PSS-SDV columns ($10^6$ Å, $10^5$ Å, $10^3$ Å). The detection system included an integrated refractive index (RI) detector and an integrated viscosity detector H502B (Visotek). All measurements were performed at 35 °C with THF as eluent. The flow rate was 1 mL/min. Sample concentrations amounted to 2–3 g/L. Molecular weight analysis was based on a universal calibration, carried out with polystyrene standards (Polymer Standard Service) in THF at 35 °C. Use of the universal calibration gave way to absolute values for the molecular weight, which are discussed as weight-averaged molar mass values $M_w$ and the polydispersity index $U$ as a measure of the width of the respective molecular weight distribution $U = M_w/M_n$ with $M_n$ the corresponding number averaged molar mass. Results are summarised in Table 1. Concomitantly, the intrinsic viscosities of the polymer samples were determined as a function of the molecular mass and correlated in the Mark–Houwink plot (Figure 5).

### Preparation of Compounds

**[$N^1$,$N^2$-Bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine]-dichloridozinc(II), [Zn(DMEG$_2$e)Cl$_2$] (C1):** The ligand $N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine (0.278 g, 1.1 mmol) was added to a solution of zinc dichloride (0.136 g, 1 mmol) in abs. MeCN (15 mL) whilst stirring. This suspension was slowly heated under reflux. A colourless precipitate could be observed; yield: 98% (0.38 g). Colourless crystals suitable for X-ray diffraction could be obtained by recrystallisation from hot MeCN (decomposition at 350 °C). $^1$H NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 3.06 (s, 12 H, $CH_3$), 3.40 (s, 8 H, $CH_2$), 3.46 (s, 4 H, $CH_2$) ppm. $^{13}$C NMR (125 MHz, $CDCl_3$, 25 °C): $\delta$ = 37.1 ($CH_3$), 49.8 ($CH_2$), 49.9 ($CH_2$), 164.4 ($C_{gua}$) ppm. IR (KBr): $\tilde{\nu}$ = 2933 [m, $\nu$(C–H)], 2867 [m, $\nu$(C–H)], 1597 [vs, $\nu$(C=N)], 1508 (m), 1446 (m), 1429 (m), 1404 (m), 1348 (m), 1296 (m), 1227 (w), 1097 (w), 1051 (w), 916 (m), 798 (vw), 766 (w), 727 (w), 652 (vw), 615 (w) cm$^{-1}$. EI-MS: $m/z$ (%) = 392 (17) [$M^+$: $C_{12}H_{24}{}^{37}Cl_2N_6{}^{66}Zn$, $C_{12}H_{24}{}^{35}Cl^{37}ClN_6{}^{68}Zn$], 391 (10) [$C_{12}H_{24}{}^{35}Cl^{37}ClN_6{}^{67}Zn$, $C_{11}{}^{13}CH_{24}{}^{35}Cl^{37}ClN_6{}^{66}Zn$, $C_{11}{}^{13}CH_{24}{}^{35}Cl_2N_6{}^{68}Zn$], 390 (46) [$M^+$: $C_{12}H_{24}{}^{35}Cl^{37}ClN_6{}^{66}Zn$, $C_{12}H_{24}{}^{37}Cl_2N_6{}^{64}Zn$, $C_{12}H_{24}{}^{35}Cl_2N_6{}^{68}Zn$], 389 (15) [$M^+$: $C_{12}H_{24}{}^{35}Cl_2N_6{}^{67}Zn$, $C_{11}{}^{13}CH_{24}{}^{35}Cl_2N_6{}^{66}Zn$, $C_{11}{}^{13}CH_{24}{}^{35}Cl^{37}ClN_6{}^{64}Zn$], 388 (71) [$M^+$: $C_{12}H_{24}{}^{35}Cl_2N_6{}^{66}Zn$, $C_{12}H_{24}{}^{35}Cl^{37}ClN_6{}^{64}Zn$], 387 (10) [$M^+$: $C_{11}{}^{13}CH_{24}{}^{35}Cl_2N_6{}^{64}Zn$], 386 (65) [$M^+$: $C_{12}H_{24}{}^{35}Cl_2N_6{}^{64}Zn$], 353 (14) [$M^+ - {}^{35}Cl$], 351 (15) [$M^+ - {}^{37}Cl$], 251 (12) [$M^+ - ZnCl_2$], 140 (6) [$C_4H_4N{=}CN_2(CH_3)_2C_2H_4^+$], 126 (100) [$CH_2N{=}CN_2(CH_3)_2C_2H_4^+$], 112 (7) [$N{=}CN_2(CH_3)_2$-$C_2H_4^+$], 98 (12) [$C_5H_{10}N_2^+$], 85 (4) [$CN_3(CH_3)_2^+ + H$], 56 (22) [$NCH_2CH_2N^+$]. $C_{12}H_{24}Cl_2N_6Zn$ (388.07): calcd. **Bis[$N^1$,$N^2$-Bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine]-zinc(II) Bis(trifluoromethanesulfonate), [Zn(DMEG$_2$e)$_2$](CF$_3$SO$_3$)$_2$ (C3):** The ligand $N^1$,$N^2$-bis(1,3-dimethylimidazolidin-2-ylidene)ethane-1,2-diamine (0.278 g, 1.1 mmol) was added to a solution of zinc bis(trifluoromethanesulfonate) (0.182 g, 0.5 mmol) in abs. THF (10 mL) whilst stirring. This suspension was slowly heated under reflux. A colourless precipitate was observed; yield: 73% (0.32 g). Colourless crystals suitable for X-ray diffraction could be obtained by recrystallisation from hot MeCN (decomposition at 350 °C). $^1$H NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 2.96 (m, 24 H, $CH_3$), 3.48 (m, 16 H, $CH_2$), 3.64 (s, 8 H, $CH_2$) ppm. $^{13}$C NMR (125 MHz, $CDCl_3$, 25 °C): $\delta$ = 35.1 ($CH_3$), 45.7 ($CH_2$), 49.2 ($CH_2$), 122.1 (C), 165.8 (C) ppm. IR (KBr): $\tilde{\nu}$ = 2941 [w, $\nu$(C–H$_{aliph.}$)], 2870 [w, $\nu$(C–H$_{aliph.}$)], 1593 [vs, $\nu$(C=N)], 1506 (m), 1458 (w), 1421 (m), 1342 (m), 1265 (s), 1221 (m), 1163 (m), 1028 (s), 916 (w), 781 (w), 725 (w), 636 (m), 573 (w), 517 (w) cm$^{-1}$. EI-MS: $m/z$ (%) = 867 (6) [M$^+$], 717 (10) [M$^+$ – $CF_3SO_3$], 567 (18) [M$^+$ – 2 $CF_3SO_3$], 251 (100) [M$^+$ – $Zn(CF_3SO_3)_2$], 167 (31) [M$^+$ – $Zn(CF_3SO_3)_2$ – $C_4H_{10}N_2$ + 2 H], 149 (99) [$CF_3SO_3^-$], 126 (54) [$CH_2N{=}CN_2(CH_3)_2C_2H_4^+$], 112 (14) [$N{=}CN_2(CH_3)_2C_2H_4^+$], 100 (21) [$C_5H_{10}N_2^+$ + 2 H], 98 (17) [$C_5H_{10}N_2^+$], 86 (16) [$C_4H_{10}N_2^+$]. $C_{26}H_{48}F_6N_{12}O_6S_2Zn$ (867.25): calcd. C 35.98, H 5.53, N 19.37; found C 35.60, H 5.22, N 19.01.

**General Procedure for Lactide Polymerisation:** D,L-Lactide (3.603 g, 25 mmol) and the initiator ($I$/$M$ ratio 1:500 or 1:1000) were weighed into a 50-mL Erlenmeyer flask that was closed with a glass stopper. The reaction vessel was then tempered at 150 °C. After the reaction time, the polymer melt was cooled to room temperature and then dissolved in dichloromethane (25 mL). The polylactide was precipitated in ice-cooled methanol (350 mL) and dried under vacuum.

# Ca-Mediated Styrene Polymerization: Tacticity Control by Ligand Design

Dirk F.-J. Piesik,[a] Karin Häbe,[b] and Sjoerd Harder*[a]

**Keywords:** Alkaline-earth metals / Calcium / Polymerization catalysis / Fluorene ligands / Polystyrene

New heteroleptic benzylcalcium complexes with modified fluorenyl ligands were prepared which include a complex with a chelating dimethylamino substituent, [9-(2-$Me_2$N-ethyl)fluorenyl][2-$Me_2$N-α-$Me_3$Si-benzyl]Ca (**4**), and a series of complexes with bulky substituents like *t*Bu-, Ph(Me)$_2$C-, Me(Ph)$_2$C- and Me(4-*t*Bu$C_6H_4$)$_2$C- in the 2- and 7-positions of the fluorenyl ligand (complexes **5** through **9**, respectively). Crystal structures of **4**, [(2,7-*t*Bu-9-$Me_3$Si-fluorenyl)(2-$Me_2$N-benzyl)Ca]$_2$ (**5**) and [2,7-Ph(Me)$_2$C-9-$Me_3$Si-fluorenyl][2-$Me_2$N-α-$Me_3$Si-benzyl]Ca·THF (**6**) show that modification of the fluorenyl ligand hardly affects the coordination mode of the benzylic ligand. Also, in solution all compounds are of heteroleptic nature and it was shown that fluorenyl modifications hardly affect the barriers for inversion at the chiral benzylic carbon atom [18.7(2)–19.2(2) kcal/mol]. Complex **4** does not initiate styrene polymerization, which underscores the importance of a free coordination site at calcium. Complexes **5**–**9** initiate styrene polymerization, and the syndiotacticity of the obtained polymers increases with the bulkiness of the substituents on the fluorenyl ligands. Syndiotacticities up to $r$ = 95 % ($rr$ = 90 %) were obtained.

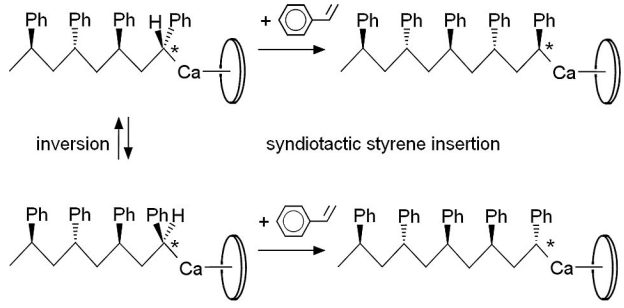
## Introduction

Syndiotactic polystyrene is a relatively young polymeric material[1,2] which receives much industrial as well as academic interest.[3–9] Its many advantageous properties,[10,11] which include a high melting point (273 °C), fast crystallization rate, high modulus, low density, low dielectric constant and excellent solvent resistance, have led to its successful application as a specialty polymer.[12]

We recently introduced a new class of polymerization initiators based on calcium which produced syndiotactic polystyrene by a chain-end-controlled monomer insertion (Scheme 1).[13–14] The initial catalyst systems consist of a polymerization-active benzyl group and a passive spectator ligand (generally a fluorenyl ligand). The monomeric (**1**)[14] and more active dimeric (**2**)[15] forms are well-defined complexes which have been structurally characterized by X-ray diffraction.

These initiators, which can be regarded as a cross-breed between organolithium initiators and cationic Ti$^{III}$ half-sandwich catalysts,[2,6] combine the advantages of a living polymerization with those of a stereoselective polymerization. Syndiotactic polystyrene, however, was only obtained for polymerization in neat styrene. This is due to the predominant ionicity and inherent weakness of the Ca–C bond, which allows for inversion of the chiral chain-end. The ratio between insertion and inversion rates, which can be controlled by monomer concentration,[14] thus controls the tacticity of the polymer (Scheme 1).



Scheme 1.

A slight improvement in stereoregularity could also be achieved by lowering the polymerization temperature.[14] Despite continuous efforts however, no significant improvement was obtained by variation of the spectator ligand. Earlier attempts to increase the syndiospecificity in styrene polymerization were based on increasing the steric bulk of the spectator ligand; that is, our initial catalyst (**1**) was modified by the introduction of a bulky hypersilyl substituent (**3**).[16] This would enforce a stronger interaction between the chiral polymer chain-end and the incoming monomer, and thus improve stereocontrol. The bulkier catalyst **3**, however, gave polystyrene of very similar tacticity but much shorter chain length. It was reasoned that the use of bulky substituents did not only result in improved communication between polymer and monomer, but also led to more stereoerrors by retarding monomer insertion and thus allowing inversion of the chiral chain-end.

In a further attempt to understand the factors that govern the stereoselectivity in calcium-mediated styrene polymerizations, we prepared a series of new benzylcalcium catalysts with modified fluorenyl ligands.

## Results and Discussion

### 1. Syntheses and Structures of Modified Heteroleptic Benzylcalcium Complexes

In order to investigate the importance of the metal's coordination sphere in the polymerization reaction, a fluorene ligand with a potential chelating dimethylamino substituent was prepared. Deprotonation by ($o$-$Me_2N$-α-$Me_3Si$-benzyl)$_2$Ca·(THF)$_2$ gave the heteroleptic benzylcalcium complex **4**.

Furthermore, the influence of steric bulk in remote positions was investigated by the introduction of large substituents in the 2- and 7-positions of the fluorenyl ligand. Several 2,7-disubstituted fluorene ligands were prepared and converted into heteroleptic benzylcalcium catalysts. In one instance, this was done by reacting the substituted fluorene with ($o$-$Me_2N$-benzyl)$_2$Ca, in which case a dimeric benzylcalcium complex was typically formed (**5**).[15] In other cases, reaction with ($o$-$Me_2N$-α-$Me_3Si$-benzyl)$_2$Ca·(THF)$_2$ gave monomeric benzylcalcium initiators (**6**–**9**). We were able to obtain crystal structures of **4** as well as representative dimeric and monomeric benzylcalcium complexes (**5** and **6**).

The heteroleptic benzylcalcium complex **4** crystallizes with two independent, but geometrically similar, molecules in the asymmetric unit (Figure 1). The fluorenyl rings coordinate in a slightly distorted η$^5$-fashion in which the Ca–C bond lengths vary between 2.630(3) and 2.782(3) Å. The average Ca–C(fluorenyl) bond of 2.710(3) Å is slightly shorter than that observed in **1** [2.743(3) Å]. Likewise, the *C*,*N*-bidentate benzyl ligand in **4** [Ca–C1 2.504(3) Å; Ca–N2 2.463 Å] is coordinated in a similar fashion to that in **1** [Ca–C 2.506(2) Å; Ca–N 2.466(2) Å]. Whereas the coordination sphere of Ca in **1** is saturated by an additional THF ligand, complex **4** crystallizes solvent-free with intramolecular coordination of the $Me_2N$ arm.

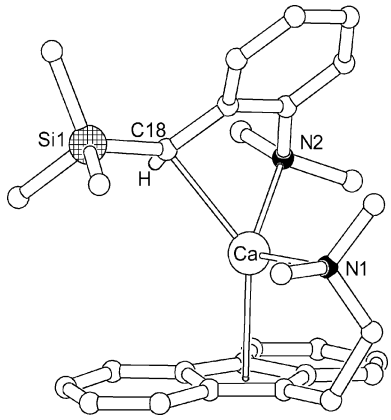

Figure 1. Crystal structure of **4**. Only one of the two crystallographically independent, but very similar, molecules is shown. Except for the benzylic hydrogen, all hydrogen atoms have been omitted for clarity. Average selected bond lengths [Å] and angles [°]: Ca–C18 2.508(3), Ca–N1 2.487(2), Ca–N2 2.460(2); Ca–C(fluorenyl): 2.630(3), 2.658(3), 2.727(3), 2.739(3), 2.782(3); C18–Ca–N1 113.6(1), C18–Ca–N2 71.4(1), N1–Ca–N2 112.0(1).

The heteroleptic complex **5** (Figure 2) crystallizes as a crystallographically $C_2$-symmetric dimer with symmetrically bridging benzyl ligands and terminal fluorenyl ligands. Its crystal structure is very much comparable to that of dimeric **2** in which the 2- and 7-positions of the fluorenyl ring are not substituted. The fluorenyl ring in **5** coordinates to Ca in $\eta^5$-fashion with Ca–C bond lengths in the range of 2.698(2) to 2.800(2) Å. The average Ca–C bond length of 2.750(2) Å is equal to that in **2** [2.750(3) Å]. Also, both symmetrically bridging benzyl anions are bound very similarly; the Ca–C17 [2.572(2) Å] and Ca–N1 [2.568(2) Å] bond lengths in **5** are equal to those in **2** [2.561(3) Å and 2.569(3) Å, respectively] within standard deviation. The bulky *t*Bu substituents in the 2- and-7 positions therefore do not affect the bonding of ligands to Ca.

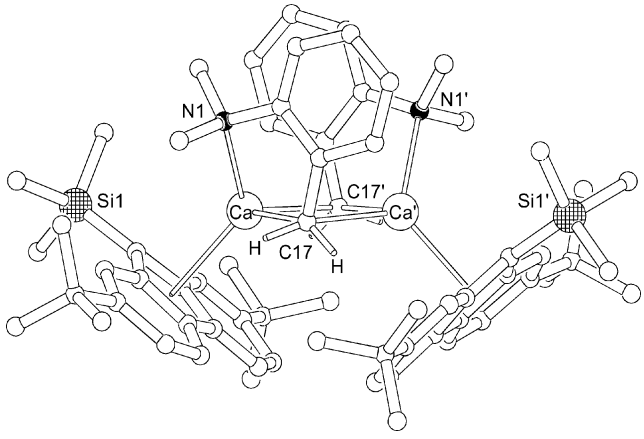

Figure 2. Crystal structure of **5**. Except for the benzylic hydrogen atoms, all hydrogen atoms have been omitted for clarity. Selected bond lengths [Å] and angles [°]: Ca–C17 2.572(2), Ca–C17′ 2.572(2), Ca–N1 2.568(2); Ca–C(fluorenyl): 2.698(2), 2.705(2), 2.749(2), 2.796(2), 2.800(2); Ca···Ca′ 3.5074(6), C17–Ca–C17′ 93.95(6), C17–Ca–N1 68.08(5), C17′–Ca–N1 120.08(5).

The heteroleptic benzylcalcium complex **6** (Figure 3) crystallizes similarly to complex **1**. The fluorenyl–Ca coordination geometry is slightly distorted from $\eta^5$-coordination. The Ca–C bond lengths range from 2.631(2) to 2.843(2) Å. The average Ca–C(fluorenyl) bond length of 2.734(2) Å compares well to that observed in **1** [2.743(3) Å]. Also, the *C*,*N*-bidentate benzyl ligand in **6** binds similarly; the Ca–C [2.517(3) Å] and Ca–N [2.496(2) Å] bond lengths for the *C*,*N*-bidentate benzyl ligand are only slightly longer than those in **1** [Ca–C: 2.506(2) Å; Ca–N: 2.466(2) Å, respectively]. In addition, the Ca–O(THF) bonds are very similar [**6**: 2.331(2) Å; **1**: 2.307(2) Å]. Therefore, the coordination geometry around Ca is hardly influenced by the large $Ph(Me)_2C$ substituents in the 2- and-7 positions of the fluorenyl ring.

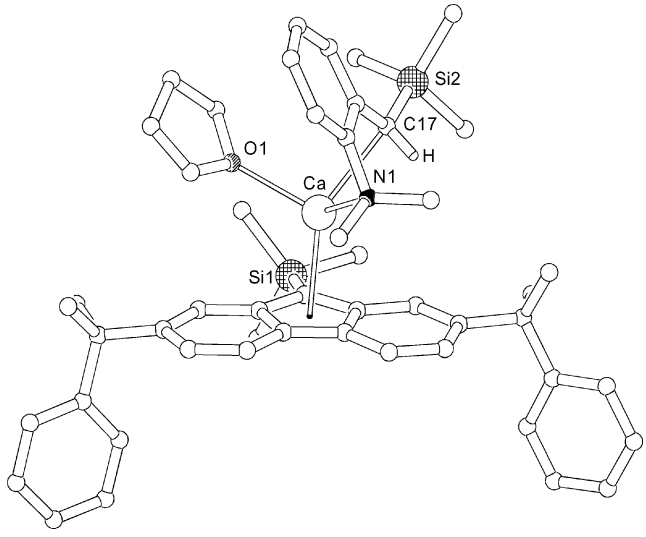

Figure 3. Crystal structure of **6**. Except for the benzylic hydrogen, all hydrogen atoms have been omitted for clarity. Selected bond lengths [Å] and angles [°]: Ca–C17 2.517(3), Ca–N1 2.496(2), Ca–O1 2.331(2); Ca–C(fluorenyl): 2.631(2), 2.647(2), 2.768(2), 2.779(2), 2.843(2); C17–Ca–N1 70.95(8), C17–Ca–O1 99.63(8), N1–Ca–O1 113.37(6).

The complexes dissolve well in aromatic solvents (except for dimer **5** which shows lower solubility), and their heteroleptic solid-state structures are retained in solution. The monomeric complexes with the chiral *o*-$Me_2N$-α-$Me_3Si$-benzyl ligand (**4** and **6**–**9**) display fluorenyl ligands with diastereotopic sides at room temperature. Fast exchange by inversion at the chiral benzylic carbon atom can be accomplished by heating the sample or by the addition of THF; both processes have been discussed previously.[14] For some of the complexes, an activation barrier for this inversion process could be determined. These values for **4** [$T_{coal}$ = 105 °C, $\Delta G^{\ddagger}$ = 19.2(2) kcal/mol] and **6** [$T_{coal}$ = 85 °C, $\Delta G^{\ddagger}$ = 18.7(2) kcal/mol] are, within standard deviation, equal to that measured for **1** [$T_{coal}$ = 90 °C, $\Delta G^{\ddagger}$ = 18.8(2) kcal/mol]. Therefore, like in the crystal structures, the bonding of the benzyl ligands to calcium is neither affected by the replacement of THF in **1** by a chelating arm, nor by the introduction of bulky substituents in the 2- and 7-positions of the fluorenyl ring.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

The benzylcalcium complex **5** is also a heteroleptic dimer in benzene solution. Proof of its dimeric nature comes from the unusual $^1$H NMR chemical shifts for the aromatic ring protons. The $^1$H NMR spectra of anionic benzyl species generally show a high-field triplet, characteristic for the aromatic ring proton in the *para*-position with respect to the benzylic carbon.[17,18] For **5**, the most high-field aromatic signal is a doublet at $\delta$ = 5.81 ppm, which can be assigned to a proton in the *meta*-position with respect to the benzylic carbon. This anomaly can be explained by the anisotropy effect caused by ring currents[19] in a nearby aryl ring: the *meta*-H is positioned in the shielding cone of the neighbouring ring. Similar observations for the analogous complex **2** have been discussed extensively.[15]

In conclusion, neither the introduction of an intramolecularly coordinating amine ligand, nor substitution of the fluorenyl ligand in the 2- and 7-positions, changes the structures of heteroleptic benzylcalcium complexes **1** and **2**. In fact, the structures and all bond lengths remain surprisingly equal. The compositions of these complexes in solution are basically similar to those in the solid state, and modification of the fluorenyl ligands does not affect the dynamic behaviour of these complexes significantly.

## 2. Styrene Polymerization with Modified Heteroleptic Benzylcalcium Complexes

Complex **4**, the benzylcalcium complex with a fluorenyl ligand containing a chelating amine arm, was found to be completely inactive as an initiator in styrene polymerization. Whereas dissociation of the THF ligand in initiator **1** generates a free site for monomer coordination, the strongly bound intramolecular $Me_2N$ substituent in **4** effectively kills the reactivity of this benzylcalcium complex towards styrene. This underscores the importance of precoordination of the styrene monomer in the insertion step. Effective benzylcalcium catalysts should therefore have a relatively open coordination sphere around the calcium metal. This observation is in line with the fact that large bulky groups in the 9-position, that is, close to the metal, substantially retard monomer insertion.[16] Therefore, modification of the fluorenyl spectator ligand in the periphery instead of close to the metal coordination site was pursued.

All of the heteroleptic complexes **5** through **9** were found to be active in styrene polymerization. Polymerizations were generally run under two different sets of conditions: a) polymerization of a 10% solution of styrene in cyclohexane at 50 °C and b) polymerization of neat styrene at 20 °C. All polymers showed a unimodal MW distribution with poly-dispersion-indexes (*D*) between 2 and 3 and a Gold distribution,[20,21] that is, tailing in the low molecular weight range (Table 1). The latter is typical of heteroleptic benzylcalcium initiators and is, as we have shown before, related to a slow initiation by the stabilized carbanion rather than to chain termination.[13–16] These rather broad molecular weight distributions, however, hinder the syntheses of well-defined block-copolymers.

The tacticity of all polymers was analyzed by $^{13}$C NMR spectroscopy, and tacticities were calculated using Bernouillain statistics based on the new heptade assignment we recently reported.[22] Figure 4a shows the $^{13}$C NMR signals for the $C_{ipso}$ atom in the phenyl rings of the different polystyrenes obtained in solution at 50 °C. Under these conditions, polymer produced by initiator **1** is essentially atactic (the signals in the *mr* and *rr* regions are only slightly high relative to those from an atactic polymer produced by an alkyllithium initiator). Polymer obtained with initiator **5**, that is, an initiator with additional *t*Bu groups in the 2- and 7-positions of the fluorenyl ring, showed a noticeable increase in syndiotactity ($r$ = 87%). The $^{13}$C NMR signal for the $C_{ipso}$ atom merely consists of four singlets which represent the *rrrrrr* heptade and the three erroneous heptades formed after a single stereochemically wrong insertion (*mrrrrr*, *rmrrrr* and *rrmrrr*). Substitution of the *t*Bu groups for the more bulky $Ph(Me)_2C$ substituents (**6**) again leads to improvement of the polymer's syndiotacticity; the largest signal is that of the *rrrrrr* heptade ($r$ = 88%). Further increase of steric bulk by the introduction of $(Ph)_2MeC$ substituents (**7**) gave a polymer of 92% syndiotacticity in diads. Subsequent increase of steric bulk by substitution of the $Me_3Si$ group for $Et_3Si$ (**8**) or by additional *t*Bu substituents on the Ph rings (**9**) gave no significant improvement of the tacticity.

Spurred by the advantageous effect of steric bulk on the syndioselectivity of styrene polymerization in solution, we

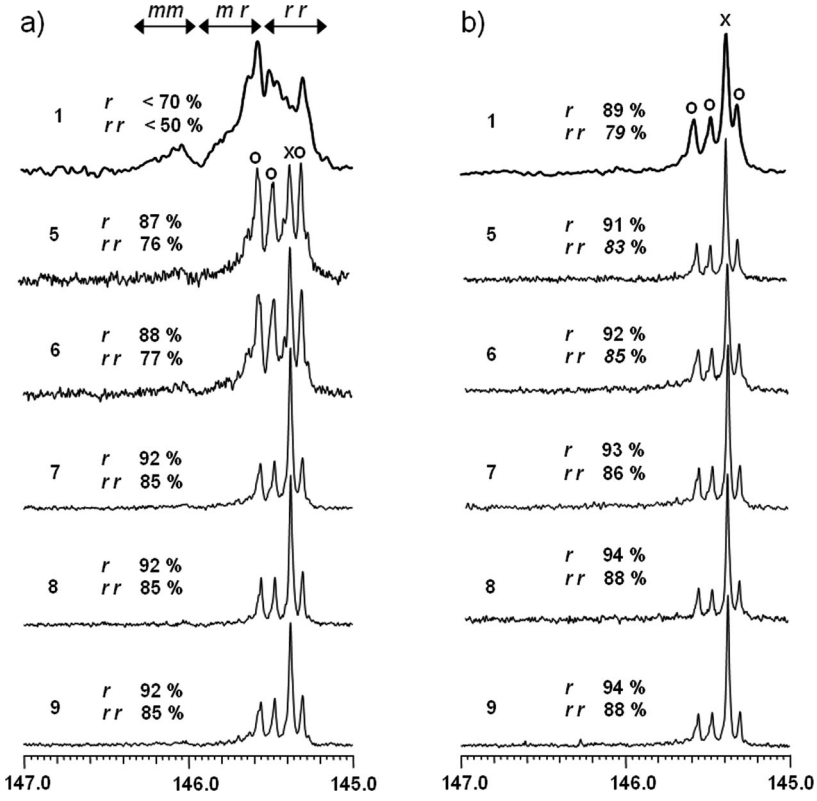

Figure 4. $^{13}C$ NMR signals of the phenyl $C_{ipso}$ atom in the polystyrene materials ([$D_2$]tetrachloroethane, $T$ = 100 °C). a) Polymers obtained with the various initiators **1**, **5**–**9**; 10% styrene solutions in cyclohexane; 50 °C. b) Polymers obtained with the various initiators **1**, **5**–**9**; 100% styrene; 20 °C. The syndiotactic *rrrrrr* heptade is marked by ×, and the error heptades *mrrrrr*, *rmrrrr* and *rrmrrr* by o.

also performed polymerization studies in pure styrene (Figure 4b). Polymers obtained under these conditions generally show much higher syndiotacticities than the polymers produced by polymerization in solution.[14–16] This is partly due to a temperature effect (for polymerizations in solution, improved syndiotacticity is also observed at lower temperature; Figure 5), but is also related to a higher ratio of the insertion to inversion rates on account of the higher monomer concentration (Scheme 1). The positive effect of increasing steric bulk in the 2- and 7-positions of the fluorenyl ring on the syndiotacticity of the polymer is also noticeable for polymerizations in neat styrene. It is, however, less extreme than that observed for polymerizations in solution. The most syndiotactic polymer was obtained with the most bulky calcium initiator **9** at –20 °C ($r$ = 95%, $rr$ = 90%); however, rather slow polymerization and a broad molecular weight distribution were observed (Table 1).

The data for polymerization in solution in particular show a clear increase in stereoselectivity upon increase in the steric bulk of the substituents in the periphery of the ligand system. The reason for this trend is unclear. Figure 6 shows space-filling models of fluorenyl–Ca units containing differently substituted ligand systems. It is evident from the structural studies (vide supra) that substitution in the 2- and 7-positions of the fluorenyl ligand has a negligible effect on the coordination sphere of the $Ca^{2+}$ ion. It can only be speculated that the sterically large groups at the sides of the fluorenyl ligand restrict the dynamic behaviour of the polymer chain attached to calcium. Reducing the degrees of freedom of the polymer chain and the coordinated styrene would lead to a higher selectivity in the insertion step.

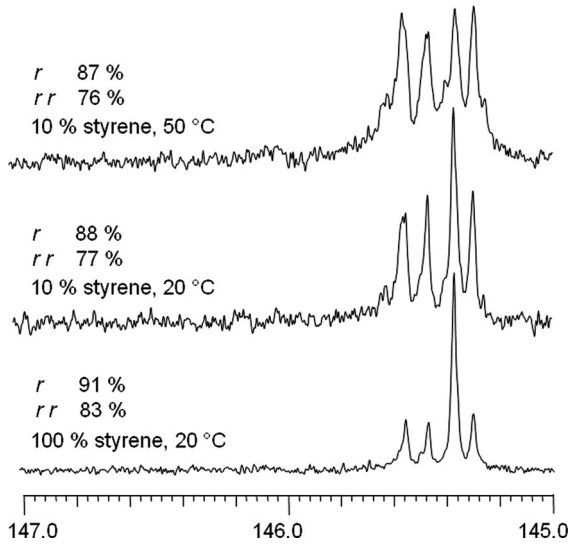

Figure 5. $^{13}C$ NMR signals of the phenyl $C_{ipso}$ atom in the polystyrene materials ([$D_2$]tetrachloroethane, $T$ = 100 °C) obtained with initiator **5** under various conditions.

## Conclusions

Replacing the THF ligand in **1** with an intramolecular chelating amine ligand does not affect the coordination of the *o*-$Me_2N$-α-$Me_3Si$-benzyl ligand. Also, the introduction of bulky substituents in the 2- and 7-positions of the fluorenyl ligand has no influence on ligand coordination to the metal. In all cases, very similar fluorenyl–Ca and benzyl–Ca coordination geometries are observed.

The composition and structures of the benzylcalcium complexes **4**–**9** in solution (benzene, toluene) are similar to those observed in the solid state; that is, the Schlenk equilibria lie completely towards the heteroleptic side, and the chiral benzylic carbon is configurationally stable on the NMR time scale (the fluorenyl ligands show diastereotopic sides). Also, the dynamic inversion of the chiral benzylic carbon at higher temperatures is not affected by the ligand modifications.

On the other hand, a significant effect of fluorenyl ligand modifications was observed on the polymerization of styrene. First of all, substitution of THF in **1** for an intramolecularly coordinated $Me_2N$ substituent effectively kills the reactivity of this benzylcalcium complex towards styrene. Apparently, the strongly bound chelate arm prevents the formation of a free coordination site, which effectively blocks the polymerization reaction. Secondly, an increase in the steric bulk of the substituents in the periphery of the fluorenyl ligand resulted in greater syndioselectivity in styrene polymerization.

These are important observations from which it can be deduced that these benzylcalcium complexes likely function as single-site catalysts in which precoordination of the monomer and subsequent insertion are the key steps in styrene polymerization. These new initiators allow syndioselective styrene polymerization not only in neat styrene, but also in solution. The broad molecular weight distributions, however, disable syntheses of well-defined block-copolymers.

## Experimental Section

**General Comments:** All experiments were carried out under argon using predried solvents and Schlenk techniques. The following starting materials were prepared according to literature: [(2-$Me_2N$-α-$Me_3Si$-benzyl)]$_2$Ca·$(THF)_2$,[13] [9-(2-dimethylamino)ethyl]fluorene,[23] 2,7-di-*tert*-butylfluorene[24] and 2,7-bis(1-methyl-1-phenylethyl)fluorene.[25] $Me_3SiCl$ was freed from HCl by distillation from dry *N*,*N*-diethylaniline. Other reagents were commercially available and used as received. NMR spectra were recorded with Bruker DPX300 and DRX500 machines.

**Synthesis of 2,7-Bis(1,1-diphenylethyl)fluorene:** 2,7-Dibenzoylfluorene was prepared according to a modified literature procedure.[25] A mixture of fluorene (10.0 g, 60.2 mmol), benzoic acid (16.0 g, 131 mmol) and polyphosphoric acid (200 g) was heated to 140 °C in a conical flask for 50 h. The cooled mixture was treated carefully with ice/water and, in later stages, with a hot aqueous potassium hydroxide solution. The heated suspension was filtered, and the residue dissolved in toluene. After aqueous workup and drying of the organic layer, the solution was concentrated and 2,7-dibenzoylfluorene precipitated at room temperature (10.7 g, 48%), m.p. 193 °C. $^1$H NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 8.01 (s, 2 H, fluorenyl), 7.96–7.82 (m, 8 H, Ar), 7.62–7.58 (m, 2 H, Ar), 7.51–7.46 (m, 4 H, Ar), 4.04 (s, 2 H, $CH_2$) ppm. $^{13}$C{$^1$H} NMR (300 MHz, $CDCl_3$): $\delta$ = 196.6 (C=O), 144.5, 144.2, 137.9, 136.9, 132.3, 130.0, 129.7, 128.3, 126.9, 120.4, 36.9 ($CH_2$) ppm. $C_{27}H_{18}O_2$ (374.4): calcd. C 86.61, H 4.85; found C 86.62, H 4.81.

A twofold excess of phenylmagnesium bromide (14.5 g, 80.0 mmol) was added to a solution of 2,7-dibenzoylfluorene (7.80 g, 20.8 mmol) in toluene (100 mL) and was heated at reflux for 4 h. After hydrolysis with 2 N HCl and extraction with toluene, the organic layer was dried. 2,7-Bis(hydroxydiphenylmethyl)fluorene was crystallized from a concentrated solution at –22 °C (7.35 g, 67%), m.p. 253 °C. $^1$H NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 7.63 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, fluorenyl), 7.41 (s, 2 H, fluorenyl), 7.32–7.18 (m, 22 H, Ar), 3.74 (s, 2 H, $CH_2$), 2.78 (s, 2 H, OH) ppm. $^{13}$C{$^1$H} NMR (300 MHz, $CDCl_3$): $\delta$ = 147.4, 146.1, 143.8, 140.8, 128.3, 128.3, 127.6, 127.3, 124.9, 119.6, 82.6 (COH), 37.5 ($CH_2$) ppm. $C_{39}H_{30}O_2$ (530.7): calcd. C 88.27, H 5.70; found C 88.26, H 5.90.

To a suspension of 2,7-bis(hydroxydiphenylmethyl)fluorene (7.35 g, 13.8 mmol) in toluene (100 mL) and acetic acid (0.2 mL) was added a trimethylaluminum solution (2.0 M in toluene, 35 mL, 70.0 mmol). After being heated at reflux for 4 h, the mixture was poured into ice/water. The remaining product was dissolved in concentrated hydrochloric acid (20 mL), and the aqueous layer was extracted with dichloromethane. The organic solution was dried, and the solvent was removed. 2,7-Bis(1,1-diphenylethyl)fluorene was obtained as a white solid product (5.75 g, 79%), m.p. 217 °C. $^1$H NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 7.60 (d, $^3J_{H,H}$ = 8.1 Hz, 2 H, fluorenyl), 7.25–6.88 (m, 24 H, Ar), 3.71 (s, 2 H, $CH_2$), 2.22 (s, 6 H, $CH_3$) ppm. $^{13}$C{$^1$H} NMR (300 MHz, $CDCl_3$): $\delta$ = 149.8, 148.2, 143.7, 139.8, 129.3, 128.3, 128.1, 126.4, 125.8, 119.5, 53.1 [($CCH_3)_2$], 37.6 ($CH_2$), 31.2 ($CH_3$) ppm. $C_{41}H_{34}$ (526.7): calcd. C 93.49, H 6.51; found C 93.16, H 6.45.

**Synthesis of 2,7-Bis[1,1-bis(4′-*tert*-butylphenyl)ethyl]fluorene:** The first intermediate, 2,7-bis(4′-*t*Bu-benzoyl)fluorene, was prepared analogously to 2,7-dibenzoylfluorene (vide supra). After quenching the reaction with water and aqueous potassium hydroxide, the residue was extracted with dichloromethane, dried and isolated by removal of the solvent. Crystallization from acetone at –27 °C gave 2,7-bis(4′-*t*Bu-benzoyl)fluorene (26.8 g, 43%) as a white solid, m.p. 251 °C. $^1$H NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 8.05 (s, 2 H, fluor-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

enyl), 7.96–7.88 (m, 4 H, fluorenyl), 7.81 (d, $^3J_{H,H}$ = 8.1 Hz, 4 H, Ar), 7.53 (d, $^3J_{H,H}$ = 8.3 Hz, 4 H, Ar), 4.05 (s, 2 H, $CH_2$), 1.39 (s, 18 H, $CH_3$) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$): $\delta$ = 197.0 (C=O), 156.9, 145.2, 144.9, 138.0, 135.8, 130.8, 130.3, 127.6, 126.0, 121.1, 37.7 ($CH_2$), 35.9 ($CCH_3$), 31.9 ($CH_3$) ppm. $C_{35}H_{34}O_2$ (486.6): calcd. C 86.38, H 7.04; found C 85.99, H 7.18.

A twofold excess of 4-*t*Bu-phenylmagnesium bromide (19.9 g, 84.0 mmol) was added to a solution of 2,7-bis(4′-*t*Bu-benzoyl)fluorene (10.0 g, 20.5 mmol) in toluene (100 mL), and was heated at reflux for 6.5 h. After the reaction mixture was hydrolyzed with 2 N HCl, extracted with diethyl ether and dried, the solvent was removed. 2,7-Bis[hydroxybis(4′-*t*Bu-phenyl)methyl]fluorene crystallized from hexane at room temperature as a white solid (11.5 g, 74%), m.p. 249 °C. $^1H$ NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 7.56 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, fluorenyl), 7.43 (s, 2 H, fluorenyl), 7.26–7.08 (m, 18 H, Ar), 3.73 (s, 2 H, $CH_2$), 2.72 (br s, 2 H, OH), 1.23 (s, 36 H, $CH_3$) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$): $\delta$ = 150.0, 145.8, 144.2, 143.3, 140.3, 127.6, 126.8, 124.8, 124.4, 119.0, 81.9 (COH), 37.7 ($CH_2$), 34.5 [$C(CH_3)_3$], 31.3 [$C(CH_3)_3$] ppm. $C_{55}H_{62}O_2$ (755.1): calcd. C 87.49, H 8.28; found C 87.07, H 7.97.

To a suspension of 2,7-bis[hydroxybis(4′-*t*Bu-phenyl)methyl]fluorene (4.80 g, 6.36 mmol) in toluene (100 mL) and acetic acid (0.2 mL) was added a trimethylaluminum solution (2.0 M in toluene, 12.5 mL, 25.0 mmol). After heating the mixture for 5 h, the solution was poured into ice/water. After aqueous workup and drying of the organic layer, the solvent was removed. 2,7-Bis[1,1-bis(4′-*t*Bu-phenyl)ethyl]fluorene was obtained as a white solid after washing with hexane (3.92 g, 82%), m.p. 311 °C. $^1H$ NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 7.54 (d, $^3J_{H,H}$ = 8.1 Hz, 2 H, fluorenyl), 7.23–7.18 (m, 10 H, Ar), 7.01–6.95 (m, 10 H, Ar), 3.69 (s, 2 H, $CH_2$), 2.13 (s, 6 H, $CH_3$), 1.24 (s, 36 H, $CH_3$) ppm. $^{13}C$ NMR$\{^1H\}$ (300 MHz, $CDCl_3$): $\delta$ = 148.4, 148.1, 146.4, 143.1, 139.2, 128.3, 127.6, 125.2, 124.6, 118.8, 51.8 ($CCH_3$), 37.1 ($CH_2$), 34.3 [$C(CH_3)_3$], 31.4 [$C(CH_3)_3$], 30.6 ($CCH_3$) ppm. $C_{57}H_{66}$ (751.1): calcd. C 91.14, H 8.86; found C 90.61, H 8.78.

**Synthesis of 2,7-Di-*tert*-butyl-9-(trimethylsilyl)fluorene:** *n*-Butyllithium (2.5 M in hexane, 12.0 mL, 30.0 mmol) was added to a precooled (–70 °C), stirred solution of 2,7-di-*tert*-butylfluorene[24] (7.70 g, 27.7 mmol) in THF (50 mL). The solution was slowly warmed to –10 °C and stirred for 30 min at this temperature, then cooled again to –70 °C, and chlorotrimethylsilane (4.1 mL, 32.2 mmol) was added. The cooling bath was removed, and the solution was stirred at room temperature for 24 h. After aqueous workup, the solvent was removed under vacuum, and colourless needles were recovered (8.65 g, 89%), m.p. 145 °C. $^1H$ NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 7.74 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, fluorenyl), 7.53 (s, 2 H, fluorenyl), 7.38 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, fluorenyl), 3.83 (s, 1 H, CH), 1.42 (s, 18 H, $CH_3$), –0.04 (s, 9 H, $Me_3Si$) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$): $\delta$ = 148.6, 145.6, 137.9, 122.2, 121.0, 119.0, 42.5 ($CH_2$), 34.8 [$C(CH_3)_3$], 31.7 [$C(CH_3)_3$], –2.60 ($Me_3Si$) ppm. $C_{24}H_{34}Si$ (350.6): calcd. C 82.22, H 9.77; found C 81.82, H 9.94.

**Synthesis of 2,7-Bis(1-methyl-1-phenylethyl)-9-(trimethylsilyl)fluorene:** This compound was synthesized according to the preparation of 2,7-bis(*t*Bu)-9-$Me_3Si$-fluorene. Colourless needles crystallized from acetone at –28 °C (72%), m.p. 122 °C. $^1H$ NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 7.71 (d, $^3J_{H,H}$ = 7.9 Hz, 2 H, fluorenyl), 7.32–7.15 (m, 14 H, Ar), 3.71 (s, 1 H, CH), 1.77 (s, 6 H, $CH_3$), 1.75 (s, 6 H, $CH_3$), –0.23 (s, 9 H, $Me_3Si$) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$): $\delta$ = 151.3, 148.4, 145.6, 137.8, 127.9, 126.8, 125.5, 123.7, 122.9, 119.0, 43.1 [$(CCH_3)_2$], 42.5 [$(CCH_3)_2$], 31.1 ($CH_3$), 30.8 ($CH_3$), –2.81 ($Me_3Si$) ppm. $C_{34}H_{38}Si$ (474.8): calcd. C 86.02, H 8.07; found C 85.96, H 7.94.

**Synthesis of 2,7-Bis(1,1-diphenylethyl)-9-$Me_3Si$-fluorene:** This compound was synthesized according to the preparation of 2,7-bis(*t*Bu)-9-$Me_3Si$-fluorene. A white solid precipitated from acetone at –28 °C (88%), m.p. 143 °C. $^1H$ NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 7.63 (d, $^3J_{H,H}$ = 7.4 Hz, 2 H, fluorenyl), 7.25–7.03 (m, 24 H, Ar), 3.57 (s, 1 H, CH), 2.18 (s, 6 H, $CH_3$), –0.40 (s, 9 H, $Me_3Si$) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$): $\delta$ = 149.6, 146.9, 145.6, 138.0, 128.8, 127.8, 125.9, 125.7, 124.9, 119.1, 52.7 ($CCH_3$), 42.7 (CH), 30.7 ($CH_3$), –2.84 ($Me_3Si$) ppm. $C_{44}H_{42}Si$ (598.9): calcd. C 88.24, H 7.07; found C 87.38, H 7.22.

**Synthesis of 2,7-Bis[1,1-bis(4′-*t*Bu-phenyl)ethyl]-9-$Me_3Si$-fluorene:** This compound was synthesized according to the preparation of 2,7-bis(*t*Bu)-9-$Me_3Si$-fluorene. A white solid precipitated from toluene at –28 °C (79%), m.p. 247 °C. $^1H$ NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 7.62 (d, $^3J_{H,H}$ = 8.1 Hz, 2 H, fluorenyl), 7.21–6.90 (m, 20 H, Ar), 3.51 (s, 1 H, CH), 2.14 (s, 6 H, $CCH_3$), 1.22 [s, 36 H, $C(CH_3)_3$], –0.48 (s, 9 H, $Me_3Si$) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $CDCl_3$): $\delta$ = 148.4, 147.4, 146.6, 145.4, 137.9, 128.3, 125.4, 125.2, 124.6, 118.9, 51.8 ($CCH_3$), 42.5 (CH), 34.3 [$C(CH_3)_3$], 31.4 [$C(CH_3)_3$], 30.4 ($CCH_3$), –2.75 ($Me_3Si$) ppm. $C_{60}H_{74}Si$ (823.3): calcd. C 87.53, H 9.06; found C 87.28, H 9.02.

**Synthesis of 2,7-Bis(1,1-diphenylethyl)-9-$Et_3Si$-fluorene:** *n*-Butyllithium (2.45 M in hexane, 1.88 mL, 4.61 mmol) was added to a precooled (–70 °C), stirred solution of 2,7-bis(1,1-diphenylethyl)fluorene (2.20 g, 4.18 mmol) in THF (50 mL). After being slowly heated to –10 °C and stirred over a period of 30 min at this temperature, the solution was recooled (–70 °C), and chlorotriethylsilane (0.78 mL, 4.66 mmol) was added. The cooling bath was removed, and the solution was stirred at room temperature for 20 h. After aqueous workup, the solvent was removed. 2,7-Bis(1,1-diphenylethyl)-9-$Et_3Si$-fluorene precipitated from acetone at –28 °C as a pale yellow solid (2.26 g, 84%), m.p. 103 °C. $^1H$ NMR (300 MHz, $CDCl_3$, 25 °C): $\delta$ = 7.65 (d, $^3J_{H,H}$ = 8.1 Hz, 2 H, fluorenyl), 7.21–7.00 (m, 22 H, Ar), 6.93 (s, 2 H, fluorenyl), 3.69 (s, 1 H, CH), 2.17 (s, 6 H, $CH_3$), 0.51 [t, 9 H, $Si(CH_2CH_3)_3$], 0.08 [q, 6 H, $Si(CH_2CH_3)_3$] ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $C_6D_6$): $\delta$ = 150.6, 150.3, 147.8, 146.6, 139.2, 126.7, 126.7, 126.5, 126.1, 120.1, 53.5 ($CCH_3$), 39.8 (CH), 31.3 ($CH_3$), 8.00 [$Si(CH_2CH_3)_3$], 3.00 [$Si(CH_2CH_3)_3$]. $C_{47}H_{48}Si$ (641.0): calcd. C 88.07, H 7.55; found C 87.88, H 7.34.

**Synthesis of 4:** A solution of [9-(2-dimethylamino)ethyl]fluorene[23] (734 mg, 3.09 mmol) and $[(2\text{-}Me_2N\text{-}\alpha\text{-}Me_3Si\text{-benzyl})]_2Ca\cdot(THF)_2$[13] (1.87 g, 3.13 mmol) in toluene (20 mL) was heated to 85 °C over a period of 5 h. All volatiles were removed, and the product was dried under vacuum to yield complex **4** with one molecule of THF. Drying of this product under vacuum over a period of 30 min (90 °C, 1 Torr) and cooling a toluene solution thereof to –30 °C gave yellow-orange plates of **4** (1.09 g, 73%) which are only soluble in hot benzene. NMR spectroscopic data are given for **4** with one equivalent of THF; m.p. 132 °C. $^1H$ NMR (300 MHz, $C_6D_6$, 25 °C): $\delta$ = 8.33 (d, $^3J_{H,H}$ = 8.1 Hz, 1 H, fluorenyl), 8.23 (d, $^3J_{H,H}$ = 8.0 Hz, 1 H, fluorenyl), 7.69 (d, $^3J_{H,H}$ = 8.3 Hz, 1 H, fluorenyl), 7.56 (t, $^3J_{H,H}$ = 8.1 Hz, 1 H, fluorenyl), 7.45 (d, $^3J_{H,H}$ = 8.4 Hz, 1 H, fluorenyl), 7.29–7.22 (m, 2 H, fluorenyl), 7.10–6.99 (m, 2 H, Ar and fluorenyl), 6.80 (t, $^3J_{H,H}$ = 7.1 Hz, 1 H, Ar), 6.35 (d, $^3J_{H,H}$ = 7.0 Hz, 1 H, Ar), 6.25 (t, $^3J_{H,H}$ = 7.1 Hz, 1 H, Ar), 3.13–3.09 (m, 2 H, $CH_2$), 2.89 (br., 4 H, THF), 2.84–2.76 (m, 1 H, $CH_2$), 2.30–2.19 (m, 1 H, $CH_2$), 2.15–1.72 (br., 6 H, $NCH_3$), 1.65 (s, 6 H, $NCH_3$), 1.22 (br., 4 H, THF), 0.41 (s, 9 H, $Me_3Si$), 0.14 (s, 1 H, CH) ppm. $^{13}C\{^1H\}$ NMR (300 MHz, $C_6D_6$, 25 °C): $\delta$ = 147.8,

135.6, 132.3, 131.4, 126.5 (benzyl), 124.5, 124.1, 123.5, 123.3, 122.1, 122.0 (benzyl), 119.6, 118.6, 118.4, 116.9, 116.8, 114.7 (benzyl), 112.5 (benzyl), 91.7 (C9), 68.1 (THF), 63.2, 61.3, 44.8, 44.7, 25.3 (THF), 22.8, 22.3, 2.8 ($Me_3Si$) ppm.

**Synthesis of 5:** A solution of 2,7-bis(*t*Bu)-9-$Me_3Si$-fluorene (475 mg, 1.35 mmol) and [(2-$Me_2N$-benzyl)]$_2$Ca[15] (469 mg, 1.52 mmol) in benzene (10 mL) was heated to 60 °C over a period of 2.5 h. Slow cooling of the reaction mixture to room temperature gave large yellow crystals of **5** (537 mg, 76%), m.p. 151 °C (dec.). $^1$H NMR (500 MHz, $C_6D_6$/[D$_8$]THF, 25 °C): $\delta$ = 7.85 (s, 2 H, fluorenyl), 7.74 (d, $^3J_{H,H}$ = 8.2 Hz, 2 H, fluorenyl), 6.85 (d, $^3J_{H,H}$ = 8.2 Hz, 2 H, fluorenyl), 6.34 (t, $^3J_{H,H}$ = 7.8 Hz, 1 H, benzyl), 6.31–6.21 (m, 2 H, benzyl), 5.80 (t, $^3J_{H,H}$ = 6.4 Hz, 1 H, benzyl), 2.04 (s, 6 H, $NCH_3$), 1.52 (br s, 2 H, $CH_2$), 1.33 (s, 18 H, $CH_3$), 0.44 (s, 9 H, $Me_3Si$) ppm. $^1$H NMR (500 MHz, $C_6D_6$, 25 °C): $\delta$ = 8.52 (d, $^3J_{H,H}$ = 8.6 Hz, 1 H, fluorenyl), 8.47 (d, $^3J_{H,H}$ = 8.6 Hz, 1 H, fluorenyl), 8.25 (s, 1 H, fluorenyl), 8.05 (s, 1 H, fluorenyl), 7.47 (d, $^3J_{H,H}$ = 8.5 Hz, 1 H, fluorenyl), 7.39 (d, $^3J_{H,H}$ = 8.2 Hz, 1 H, fluorenyl), 6.67 (t, $^3J_{H,H}$ = 7.3 Hz, 1 H, benzyl), 6.10 (t, $^3J_{H,H}$ = 6.9 Hz, 1 H, benzyl), 5.85 (d, $^3J_{H,H}$ = 7.8 Hz, 1 H, benzyl), 5.81 (d, $^3J_{H,H}$ = 7.2 Hz, 1 H, benzyl), 1.78 (s, 3 H, $NCH_3$), 1.51 (s, 9 H, $CH_3$), 1.42 (s, 9 H, $CH_3$), 1.24 (s, 3 H, $NCH_3$), 0.73 (s, 9 H, $Me_3Si$), –0.55 (d, $^2J_{H,H}$ = 11.8 Hz, 1 H, $CH_2$), –0.96 (d, $^2J_{H,H}$ = 11.7 Hz, 1 H, $CH_2$) ppm. $^{13}$C{$^1$H} NMR (500 MHz, $C_6D_6$/[D$_8$]THF, 25 °C): $\delta$ = 148.0, 143.5, 143.3, 136.9, 125.4 (benzyl), 123.0, 122.3 (benzyl), 120.1, 117.9 (benzyl), 116.1, 112.8, 110.0 (benzyl), 85.2 (C-9), 43.3 [$N(CH_3)_2$], 40.9 ($CH_2$), 34.8 [$C(CH_3)_3$], 32.1 [$C(CH_3)_3$], 2.39 ($Me_3Si$) ppm.

**Synthesis of 6:** A mixture of 2,7-bis(1-methyl-1-phenylethyl)-9-$Me_3Si$-fluorene (315 mg, 664 μmol) and [(2-$Me_2N$-α-$Me_3Si$-benzyl)]$_2$Ca·(THF)$_2$[13] (417 mg, 698 μmol) in THF (4.0 mL) was stirred for 2.5 h at 60 °C. The solvent was removed under vacuum, and the remaining orange product was dissolved in warm hexane (4 mL). Cooling the solution to room temperature yielded yellow crystals (410 mg, 80%), m.p. 132 °C (dec.). $^1$H NMR (500 MHz, $C_6D_6$, 25 °C): $\delta$ = 8.15 (s, 1 H, fluorenyl), 8.00 (s, 1 H, fluorenyl), 7.89 (d, $^3J_{H,H}$ = 8.5 Hz, 1 H, fluorenyl), 7.79 (d, $^3J_{H,H}$ = 8.5 Hz, 1 H, fluorenyl), 7.41 (d, $^3J_{H,H}$ = 7.5 Hz, 2 H, Ar), 7.34 (d, $^3J_{H,H}$ = 7.5 Hz, 2 H, Ar), 7.22–6.91 (m, 8 H, Ar), 6.86 (d, $^3J_{H,H}$ = 8.5 Hz, 1 H, benzyl), 6.67 (t, $^3J_{H,H}$ = 7.1 Hz, 1 H, benzyl), 6.32 (d, $^3J_{H,H}$ = 7.6 Hz, 1 H, benzyl), 6.19 (t, $^3J_{H,H}$ = 7.1 Hz, 1 H, benzyl), 2.63 (br., 4 H, THF), 1.96 (s, 3 H, $CH_3$), 1.87 (s, 3 H, $CH_3$), 1.85 (s, 3 H, $NCH_3$), 1.84 (s, 3 H, $NCH_3$), 1.79 (s, 6 H, $CH_3$), 0.95 (br., 4 H, THF), 0.64 (s, 9 H, $Me_3Si$-fluorenyl), 0.51 (s, 1 H, CH), 0.45 (s, 9 H, $Me_3Si$-benzyl) ppm. $^{13}$C{$^1$H} NMR (500 MHz, $C_6D_6$, 25 °C): $\delta$ = 151.4, 151.2, 147.2, 146.1, 145.6, 141.6, 141.4, 136.1, 128.3, 127.3, 127.2, 125.9, 125.9, 125.5 (benzyl), 123.9 (benzyl), 121.4, 121.3, 121.2, 121.0, 119.2 (benzyl), 118.2, 118.2, 118.0, 117.6, 113.1 (benzyl), 87.9 (C-9), 68.5 (THF), 44.8 ($NCH_3$), 44.4 (CH), 43.6 [$C(CH_3)_2$], 43.4 [$C(CH_3)_2$], 41.5 ($NCH_3$), 31.4 ($CH_3$), 31.3 ($CH_3$), 30.9 ($CH_3$), 30.7 ($CH_3$), 24.9 (THF), 2.71 ($Me_3Si$-fluorenyl), 2.48 ($Me_3Si$-benzyl) ppm.

**Synthesis of 7:** A solution of 2,7-bis(1,1-diphenylethyl)-9-$Me_3Si$-fluorene (242 mg, 404 μmol) and [(2-$Me_2N$-α-$Me_3Si$-benzyl)]$_2$Ca·(THF)$_2$[13] (245 mg, 410 μmol) in THF (3.0 mL) was stirred for 2.5 h at 60 °C. After removing the solvent under vacuum, the remaining product was washed with hexane (2 mL) and dried in vacuo. Repeating this procedure resulted in a yellow product (307 mg, 83%), m.p. 202 °C (dec.). $^1$H NMR (500 MHz, $C_6D_6$, 25 °C): $\delta$ = 8.02 (d, $^3J_{H,H}$ = 8.6 Hz, 1 H, fluorenyl), 7.95 (d, $^3J_{H,H}$ = 8.6 Hz, 1 H, fluorenyl), 7.61 (s, 1 H, fluorenyl), 7.52 (s, 1 H, fluorenyl), 7.33–6.96 (m, 23 H, Ar), 6.69 (t, $^3J_{H,H}$ = 7.3 Hz, 1 H, benzyl), 6.30 (d, $^3J_{H,H}$ = 7.1 Hz, 1 H, benzyl), 6.17 (t, $^3J_{H,H}$ = 7.2 Hz, 1 H, benzyl), 2.61 (br., 4 H, THF), 2.26 (s, 3 H, $CH_3$), 2.23 (s, 3 H, $CH_3$), 1.87 (s, 3 H, $NCH_3$), 1.81 (s, 3 H, $NCH_3$), 0.97 (br., 4 H, THF), 0.45 (s, 1 H, CH), 0.34 (s, 9 H, $Me_3Si$-fluorenyl), 0.24 (s, 9 H, $Me_3Si$-benzyl) ppm. $^{13}$C{$^1$H} NMR (500 MHz, $C_6D_6$, 25 °C): $\delta$ = 150.6, 150.2, 150.2, 150.1, 147.3, 144.4, 143.7, 141.4, 141.2, 129.4, 129.4, 129.3, 129.2, 129.2, 128.3, 128.1, 128.1, 128.0, 126.5, 126.2, 126.2, 126.1, 126.0, 124.5, 121.7 (benzyl), 121.5, 121.5, 121.3, 121.2 (benzyl), 119.3, 118.7 (benzyl), 113.0 (benzyl), 88.9 (C-9), 68.6 (THF), 53.4 ($CCH_3$), 53.2 ($CCH_3$), 44.8 (CH), 44.6 ($NCH_3$), 41.5 ($NCH_3$), 30.9 ($CH_3$), 30.3 ($CH_3$), 25.0 (THF), 2.56 ($Me_3Si$-fluorenyl), 2.19 ($Me_3Si$-benzyl) ppm.

**Synthesis of 8:** As complex **8** is highly soluble even in cold hexane, it was synthesized in situ by reacting 2,7-bis(1,1-diphenylethyl)-9-$Et_3Si$-fluorene with [(2-$Me_2N$-α-$Me_3Si$-benzyl)]$_2$Ca·(THF)$_2$ (1.05 equiv.) in $C_6D_6$. Stirring the orange solution for 50 h at 70 °C led to quantitative formation of the heteroleptic complex **8** which, because of its extreme solubility, could not be freed from 2-$Me_2N$-α-$Me_3Si$-toluene by washing procedures. It was therefore used in solution for further polymerization experiments. The product has been fully characterized by 2D NMR methods. $^1$H NMR (500 MHz, $C_6D_6$, 25 °C): $\delta$ = 7.93 (d, $^3J_{H,H}$ = 8.5 Hz, 1 H, fluorenyl), 7.87 (d, $^3J_{H,H}$ = 8.5 Hz, 1 H, fluorenyl), 7.58 (s, 1 H, fluorenyl), 7.43 (s, 1 H, fluorenyl), 7.22–6.83 (m, 23 H, Ar), 6.58 (t, $^3J_{H,H}$ = 7.5 Hz, 1 H, benzyl), 6.23 (d, $^3J_{H,H}$ = 7.0 Hz, 1 H, benzyl), 6.10 (t, $^3J_{H,H}$ = 7.5 Hz, 1 H, benzyl), 2.52 (br., 4 H, THF), 2.21 (s, 3 H, $CH_3$), 2.16 (s, 3 H, $CH_3$), 1.80 [s, 6 H, $N(CH_3)_2$], 0.83–0.74 [m, 15 H, $Si(CH_2CH_3)_3$], 0.29 (s, 1 H, CH), 0.27 (s, 9 H, $Me_3Si$) ppm. $^{13}$C{$^1$H} NMR (500 MHz, $C_6D_6$, 25 °C): $\delta$ = 150.6, 150.3, 150.2, 150.1, 147.3, 144.5, 143.6, 142.0, 141.8, 130.1, 129.4, 129.4, 129.3, 129.0, 128.2, 128.1, 128.1, 128.0, 126.4 (benzyl), 126.2, 126.1, 125.4, 124.4 (benzyl), 123.9, 122.1, 121.6, 121.5, 121.4, 121.4, 121.2, 119.4, 119.1 (benzyl), 118.5, 113.0 (benzyl), 86.5 (C-9), 68.6 (THF), 53.4 ($CCH_3$), 53.2 ($CCH_3$), 45.0 (CH), 44.4 ($NCH_3$), 41.7 ($NCH_3$), 30.8 ($CH_3$), 30.2 ($CH_3$), 25.0 (THF), 8.50 [$Si(CH_2CH_3)_3$], 6.40 [$Si(CH_2CH_3)_3$], 2.58 ($Me_3Si$-benzyl) ppm.

**Synthesis of 9:** As complex **9** is highly soluble even in cold hexane, it was synthesized in situ with a procedure similar to that for **8**. The orange solution of **9** prepared in situ was used for further polymerization experiments. $^1$H NMR (500 MHz, $C_6D_6$, 25 °C): $\delta$ = 7.97 (d, $^3J_{H,H}$ = 8.5 Hz, 1 H, fluorenyl), 7.91 (d, $^3J_{H,H}$ = 9.0 Hz, 1 H, fluorenyl), 7.43 (s, 1 H, fluorenyl), 7.36 (s, 1 H, fluorenyl), 7.22–6.82 (m, 19 H, Ar), 6.57 (t, $^3J_{H,H}$ = 7.0 Hz, 1 H, benzyl), 6.27 (d, $^3J_{H,H}$ = 6.5 Hz; 1 H, benzyl), 6.10 (t, $^3J_{H,H}$ = 6.5 Hz, 1 H, benzyl), 2.70 (br., 4 H, THF), 2.26 (s, 3 H, $CH_3$), 2.24 (s, 3 H, $CH_3$), 1.90 (s, 6 H, $NCH_3$), 1.81 (s, 6 H, $NCH_3$), 1.19 [s, 9 H, $C(CH_3)_3$], 1.16 [s, 9 H, $C(CH_3)_3$], 1.15 [s, 9 H, $C(CH_3)_3$], 1.13 [s, 9 H, $C(CH_3)_3$], 1.00 (br., 4 H, THF), 0.40 (s, 1 H, CH), 0.28 (s, 9 H, $Me_3Si$-benzyl), 0.12 (s, 9 H, $Me_3Si$-fluorenyl) ppm. $^{13}$C{$^1$H} NMR (500 MHz, $C_6D_6$, 25 °C): $\delta$ = 148.6, 148.6, 147.7, 147.4, 147.3, 147.2, 147.0, 144.9, 144.6, 141.3, 141.1, 129.2, 129.1, 129.1, 129.0, 126.5 (benzyl), 125.0, 125.0, 124.5 (benzyl), 121.7, 121.5, 121.2, 121.1, 119.3, 119.3 (benzyl), 118.8, 113.0 (benzyl), 88.7 (C-9), 68.6 (THF), 52.6 ($CCH_3$), 52.5 ($CCH_3$), 44.8 (CH), 44.4 ($NCH_3$), 41.5 ($NCH_3$), 34.5 [$C(CH_3)_3$], 34.4 [$C(CH_3)_3$], 31.5 [$C(CH_3)_3$], 30.5 ($CCH_3$), 30.1 ($CCH_3$), 25.1 (THF), 2.70 ($Me_3Si$-fluorenyl), 2.22 ($Me_3Si$-benzyl) ppm.

**Styrene Polymerization:** Polymerizations of styrene were performed in a thermostatted 100 mL stainless steel Büchi reactor at normal pressure either in cyclohexane (1 M styrene solution, 1 mM catalyst, 50 °C) or in pure styrene (1 mM catalyst, 20 °C). In a typical polymerization experiment, the reactor was loaded with dry cyclohex-

ane (90 mL, dried with $CaH_2$ and distilled from *n*BuLi) and dry styrene (11.5 mL, ca. 100 mmol, freshly distilled from $CaH_2$ and stored over alox pearls). A solution of the initiator (0.1 mmol) in benzene (1.0 mL) was added through a port. The usual appearance of a red colour and a slight increase in temperature (1–3 °C) indicated that the polymerization started immediately. After a polymerization time of 45–60 min, the mixture was quenched with oxygen-free methanol. Evaporation of all solvents yielded the polymer in quantitative yields. Polymerization in neat styrene should only be carried out at temperatures ≤20 °C, should be monitored continuously and should be quenched when temperatures exceed 25 °C. The polymers were analyzed by GPC and high temperature $^1$H and $^{13}$C NMR (solvent: [D$_2$]tetrachloroethane). The tacticity of the polymer was checked by analyzing the $^{13}$C NMR signal for the $C_{ipso}$ in the phenyl ring.[22]

**Crystal Structures:** Crystal diffraction data were measured on Enraf–Nonius CAD4 and Siemens SMART CCD diffractometers. All crystal structures were solved with SHELXS-97[26] and refined with SHELXL-97.[27] PLATON[28] was used for geometry calculations and graphics. Crystal data are given in Table 2.) The space group for **4** was checked with the ADSYM procedure incorporated in the program PLATON. No additional symmetry was found, and therefore the true space group is *Cc*. The Flack parameter was refined to 0.00(2). Crystals of **6** contain one equivalent of hexane in the asymmetric unit. This molecule was extensively disordered and treated with the SQUEEZE procedure[29] incorporated in PLATON.

CCDC-646400 (compound **4**), -646401 (compound **5**), and -646402 (compound **6**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# A Basket-Like $[Sr\subset P_6Mo^{V}_4Mo^{VI}_{14}O_{73}]^{10-}$ Polyoxoanion Modified with $\{Cu(phen)(H_2O)_x\}$ ($x$ = 1–3) Fragments: Synthesis, Structure, Magnetic, and Electrochemical Properties

**Kai Yu,[a] Yang-Guang Li,*[b] Bai-Bin Zhou,*[a] Zhan-Hua Su,[a] Zhi-Feng Zhao,[a] and Yu-Nan Zhang[a]**

**Keywords:** Polyoxometalate / Organic–inorganic hybrid / Basket-like / Electrocatalysis

Hydrothermal reaction of a mixture of $Na_2MoO_4{\cdot}2H_2O$, $H_3PO_4$, $CuCl_2{\cdot}2H_2O$, *o*-phenanthroline, and $SrCl_2$ in water leads to the isolation of a basket-like mixed-valent polymolybdophosphate hybrid compound, $[Cu(phen)(H_2O)_3][\{Cu(phen)(H_2O)_2\}\{Cu(phen)(H_2O)\}_3\{Sr\subset P_6Mo_4{}^{V}Mo_{14}{}^{VI}O_{73}\}]{\cdot}3H_2O$ **1**, which crystallizes in the space group $P\bar{1}$ with $a$ = 13.778(3) Å, $b$ = 19.267(4) Å, $c$ = 24.168(5) Å, $\alpha$ = 110.64(3)°, $\beta$ = 90.31(3)°, $\gamma$ = 110.02(3)°, $V$ = 5582.8(2) Å$^3$, $Z$ = 2. Single-crystal X-ray diffraction analysis shows that the four-electron-reduced basket-like polyoxoanion $[Sr\subset P_6Mo_4{}^{V}Mo_{14}{}^{VI}O_{73}]^{10-}$ contains a new tetravacant γ-Dawson-type unit and a "handle"-shaped $\{P_4Mo_4\}$ segment, which are highly modified with $\{Cu(phen)(H_2O)_x\}$ (x = 1–3) fragments. Electrochemical analysis shows that **1**-modified carbon paste electrode (CPE) displays good electrocatalytic activity to reduce hydrogen peroxide.

## Introduction

Polyoxometalate (POM)-based organic–inorganic hybrid compounds have attracted great interest in recent years owing to their extensive theoretical and practical applications in catalysis, molecular adsorption, medicine, electroconductivity, magnetism, and photochemistry.[1–7] A current research interest in this field is modification of the surface of POMs with various organic and/or transition-metal complex moieties.[1–10] These kinds of modified POM derivatives can be regarded as an ideal molecular model for determination of the mechanisms of oxide-supported catalysts.[1] Furthermore, such kinds of compounds can be molecularly fine-tuned and provide potentially new types of catalyst systems as well as interesting functional materials with optical, electronic, and magnetic properties.[1b,1c] During the preparation, two strategies have been exploited to increase the surface charge density and activate the surface oxygen atoms of heteropolyoxoanions:[1] (1) reduce the metal centers from a high oxidation state to a low oxidation state, for example, from $Mo^{VI}$ to $Mo^{V}$, by introducing strong reducing reagents or (2) replace high-valence metal centers with lower-valence ones, for instance, from $Mo^{VI}$ to $V^{IV}$ or $TM^{2+}$ (TM = transition metal). However, the highly reduced polyoxoanions are usually unstable and inclined to be oxidized in ambient atmosphere. Thus, the hydrothermal technique has been extensively employed and proved to be an efficient way to obtain metastable POMs modified by various organic and/or metal–organic fragments.[2] According to the above-mentioned strategies, a series of hybrid compounds based on Keggin- and Dawson-type heteropolytungstates have been prepared, such as $[\{Ni(bpy)_2(H_2O)\}(PW_{12}O_{40})]^{3-}$,[9a] $[\{Ag(bpy)\}_2\{Ag_2(bpy)_3\}_2(PW_9V_3O_{40})]$,[9b] $[\{Cu(bpy)_2\}(SeW_{12}O_{40})]^{3-}$,[9c] $[\{Cu(PPD)_2\}(As_2W_{18}O_{60})]$,[9d] and $[\{Zn(phen)_2\}\{Zn(phen)_2(H_2O)\}(P_2W_{18}O_{62})]$.[9e] In contrast, most modified polyoxomolybdate composite compounds in earlier research, especially in the work of Zubieta,[2a] concentrated on isopolyoxometalate-supported transition-metal complexes. When $PO_4^{3-}$ was introduced into the $\{MoO_x/TM/L\}$ (TM = transition metal, L = organic ligand) system, a series of reduced polymolybdophosphates decorated with metal–organic units were synthesized.[2b,2c,10–12] It is interesting that most of these hybrid compounds are based on inorganic $\{PMo_{12-x}TM_xO_{40}\}$,[10] $\{P_4Mo_6O_{31}\}$,[11] and $\{P_2Mo_5O_{23}\}$[12] building blocks. More recently, three unusual large clusters, $[P_6Mo_{18}O_{73}]^{11-}$,[13] $[H_{14}(Mo_{16}O_{32})Co_{16}(PO_4)_{24}(H_2O)_{20}]^{10-}$,[14] and $[Na_4(H_2O)_6\{(Mo_2O_4)_{10}(P_2O_7)_{10}(OAc)_8(H_2O)_4\}]^{24-}$[15] have been reported. However, no organic or metal–organic complexes have been successfully coordinated to these highly reduced polymolybdophosphate clusters so far, the reason for which may be that the large size of these POMs decreases the elec-

tron density of the surface or the coordination ability of the surface oxygen atoms. During our continuing research on modified-POM hybrid compounds in the $\{MoO_x/P/TM/L\}$ system, we are interested in employing metal–organic units to decorate high-nuclear clusters in order to get new hybrid materials to explore their fascinating magnetic and electrochemical properties. In this paper, we report the hydrothermal synthesis and crystal structure of a basket-like four-electron reduced polymolybdophosphate hybrid compound, $[Cu(phen)(H_2O)_3][\{Cu(phen)(H_2O)_2\}\{Cu(phen)(H_2O)\}_3\{Sr\subset P_6Mo_4{}^{V}Mo_{14}{}^{VI}O_{73}\}]\cdot 3H_2O$ **1**. In the crystal structure of **1**, the basket-like polyoxoanion contains a new tetravacant γ-Dawson-type unit and a "handle"-shaped $\{P_4Mo_4\}$ segment, which are decorated by four $\{Cu(phen)(H_2O)_x\}$ ($x$ = 1–3) fragments. The magnetic, electrochemical, and electrocatalytic properties of compound **1** were also investigated.

## Results and Discussion

### Syntheses

The successful isolation of compound **1** relies on the employment of a hydrothermal technique. Hydrothermal synthesis has recently been proved to be a particularly effective method for the preparation of new organic–inorganic hybrid materials.[2,6–15] Exploitation of hydrothermal conditions provides a paradigm shifting from the thermodynamics to the kinetics. Under such conditions, equilibrium phases are replaced by structurally more complex metastable phases.[2,16] In the hydrothermal environment, the reduced viscosity of water results in enhanced rates of solvent extraction from solids and crystal growth from solution.[2] Further, as different solubility problems can be minimized, a variety of organic and inorganic precursors can be introduced.[2] Meanwhile, hydrothermal synthesis is still a relatively complex process because many factors can influence the outcome of a reaction, such as the type of initial reactants, starting concentrations, pH value, reaction time, and temperature.[2,16] However, numerous successful experimental results from these so-called "black-box" reactions could suggest some preliminary synthetic experiences, which might be helpful for the future synthetic route.

During our exploration of the hybrid polymolybdophosphates modified with various organic and/or metal–organic complex fragments, abbreviated as the $\{MoO_x/P/TM/L\}$ (TM = transition metal; L = N donor organic ligand) system, a series of new composite compounds have been hydrothermally synthesized as shown in Table 1.[10–12] It is noteworthy that almost all the compounds can be separated into three groups on the basis of their POM building blocks, that is, $\{PMo_{12-x}TM_xO_{40}\}$, $\{P_4Mo_6O_{31}\}$, and $\{P_2Mo_5O_{23}\}$ units (see Figure 1). During the preparations, although various molar ratios of $Na_2MoO_4/H_3PO_4/TM^{2+}$/L were used, the initial pH value and the reaction temperature seem to be vital for a successful reaction. As shown in Figure 1, the $\{P_2Mo_5\}$-based composite compounds are generally isolated at 160 °C, whereas most $\{P_4Mo_6\}$-based compounds could be prepared above 180 °C. Further, both $\{P_2Mo_5\}$- and $\{P_4Mo_6\}$-based compounds can be synthesized in a wide range of pH values, whereas the $\{PMo_{12-x}TM_xO_{40}\}$-based compounds can only be prepared in a very narrow pH range of ca. 3.5–4.

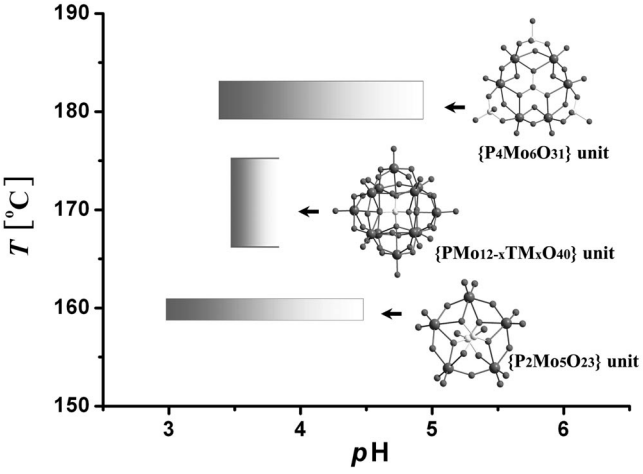

Figure 1. Illustration of possible synthetic products in the $\{MoO_x/P/TM/L\}$ system based on three kinds of building blocks under different pH and temperature conditions.

In this work, compound **1** represents an exception to the aforementioned examples. Compound **1** was synthesized with a mixture of $Na_2MoO_4\cdot 2H_2O$, $CuCl_2\cdot 2H_2O$,

phen, $H_3PO_4$, and $SrCl_2$ in a molar ratio of 1.00:0.30:0.30:4.80:0.50 in water at 160 °C for 4 d. The initial pH value was controlled in the range 3–4 with 1-M NaOH solution. If the reaction temperature was lower than 160 °C or the pH value was outside the 3–4 range, no crystals could be obtained. It is also interesting that when $SrCl_2$ was not introduced into the reaction mixture, another compound[17] was isolated under similar reaction conditions ($T$ = 165 °C and pH = 3.5), which might be analogous to the polyoxoanion $[\{Ni(phen)\}_2PMo^{V}_3Mo^{VI}_9O_{40}]^{2-}$.[10a] Thus, it is supposed that the $Sr^{2+}$ ions could be the necessary templates for the isolation of compound **1**.[18]

## Structure Description

Single-crystal X-ray diffraction analysis revealed that **1** consists of an interesting basket-like $[Sr\subset P_6Mo_{18}O_{73}]^{10-}$ polyoxoanion decorated with four $\{Cu(phen)(H_2O)_x\}$ ($x$ = 1 and 2) fragments (Figure 2) and charge balanced with one $\{Cu(phen)(H_2O)_3\}$ unit. In the polyoxoanion of **1** (Figure 3 and Figure S1), all Mo centers exhibit a six-coordinate environment with Mo–O bond lengths in the range 1.672(8)–2.454(6) Å and O–Mo–O bond angles varying from 83.4(3) to 173.7(3)°. The six P centers display tetrahedral coordination geometry. The P–O bond lengths range from 1.503(7) to 1.577(7) Å, whereas the O–P–O bond angles vary from 107.2(4) to 112.8(4)°. The basket-like polyoxoanion can be separated into two parts, that is, the "handle" $\{P_4Mo_4\}$ unit and the "basket body" $\{P_2Mo_{14}\}$ segment (Figure 2). The $\{P_4Mo_4\}$ unit consists of four $\{MoO_6\}$ octahedra and four $\{PO_4\}$ tetrahedra, which are corner-linked together to form the handle moiety. The $\{P_2Mo_{14}\}$ unit exhibits a tetravacant Dawson-type structural feature. In comparison to the Dawson-type isomers and their tetravacant species[5c] (Scheme 1), we conclude that the $\{P_2Mo_{14}\}$ building block in **1** is derived from the γ-Dawson anion. It is noteworthy that Dawson anions and a series of its lacunary derivatives have extensively acted as building blocks to constitute novel complexes with various functionalities.[1,2a,5] Nevertheless, only six kinds of lacunary Dawson-type derivatives have ever been observed (Scheme S1). In **1**, the γ-$\{P_2Mo_{14}\}$ unit represents a new lacunary Dawson-type species in POM chemistry. The "handle" ($\{P_4Mo_4\}$ unit) and the "basket body" ($\{P_2Mo_{14}\}$ unit) moieties are connected together through the edge- and/or corner-sharing modes (Figure 3 and Figure S2). The whole basket-shaped cluster possesses $C_{2v}$ symmetry (Figure S2). In the central cavity of the polyoxoanion, a $Sr^{2+}$ ion is fully encapsulated, and it exhibits a nine-coordinate environment with the bond lengths of Sr–O in the range 2.570(7)–2.754(6) Å (Figure 3 and Figure S3). It is interesting that the cavity size of the basket-

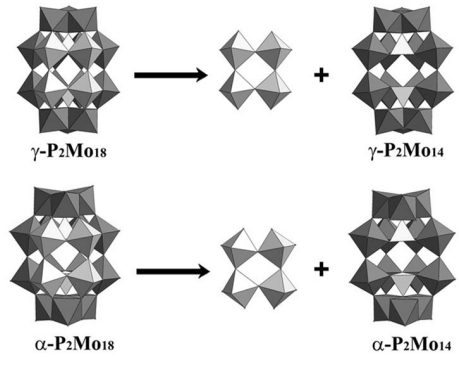

Scheme 1. Illustration of the comparison between α- and γ-Dawson-type polyoxoanions and their tetravacant derivatives.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

like polyoxoanion seems to be more inclined to capture larger cations ($Sr^{2+}$) although both $Sr^{2+}$ and $Na^+$ ions coexist in the reaction system with similar concentrations. Zhang et al. have also reported a similar $[P_6Mo_{18}O_{73}]^{11-}$ polyoxoanion encapsulating a $K^+$ ion.[13] The incorporation of these large cations may vice versa stabilize the whole cryptand polyoxoanion.[18]

In **1**, there are five independent $\{Cu(phen)(H_2O)_x\}$ ($x$ = 1, 2, or 3) fragments. Four of them are coordinated directly to the surface of the polyoxoanion, whereas the fifth is isolated in the interspace of the crystal structure (Figure 4 and Figure S4). The Cu1 atom exhibits a five-coordinate environment with two O atoms from the polyoxoanion, two N atoms from the phen ligand, and one water ligand. The Cu2 atom possesses an octahedral coordination geometry with three O atoms from the polyoxoanion, two N atoms from the phen ligand, and one terminal water ligand. The Cu3 atom also displays octahedral coordination geometry with two O atoms from the polyoxoanion, two N atoms from the phen ligand, and two terminal water ligands. The $\{Cu(4)(phen)(H_2O)\}$ moiety is disordered in two positions (Figure S4). Both of the disordered parts exhibit a four-coordinate environment. The Cu5 atom has a five-coordinate environment, involving two N atoms from the phen ligand and three coordinated water molecules. The bond lengths of Cu–N and Cu–O are in the range 1.983(1)–2.122(2) and 1.912(2)–2.619(3) Å, respectively. It is noteworthy that two $\{Cu(2)(phen)(H_2O)\}$ units act as bridges to link two polyoxoanions into a dimeric cluster (Figure 4). In the packing arrangement, the adjacent $[\{Cu(phen)(H_2O)_2\}\{Cu(phen)(H_2O)\}_3\{Sr\subset P_6Mo_{18}O_{73}\}]^{2-}$ dimeric clusters are linked together by π–π interactions between adjacent phen groups to form a three-dimensional supramolecular framework (Figure S5). The isolated $\{Cu(phen)(H_2O)_3\}$ units are also connected with their adjacent coordinated analogues through π–π interactions between the phen groups. In the crystal structure, the average distance between two phen planes with π–π interactions is about 3.52 Å. The lattice water molecules should be extensively H-bonded with the surface oxygen atoms of the polyoxoanions. The typical H-bond lengths between them are as follows: OW1···O48 2.823 Å, OW2···O5 3.168 Å, OW3···O46 2.845 Å, and OW4···O22 3.454 Å.

In compound **1**, all P, Cu, and Sr centers exhibit +5, +2, and +2 oxidation states, respectively, on the basis of their coordination environments, bond lengths and angles, and the bond valence sum (BVS) calculation.[19] In addition, the black color of the crystal suggests that the Mo centers in compound **1** should be mixed valent. BVS calculation shows an average value of ca. 5.79 for all Mo centers (Table S3), which is close to the result of 14 $Mo^{6+}$ and 4 $Mo^{5+}$ in the polyoxoanion cluster. Considering the five $[Cu(phen)(H_2O)_x]^{2+}$ segments and no protonated oxygen atoms on the surface of the polyoxoanion, together with the BVS calculation results, the polyoxoanion formula can be expressed as $[Sr\subset P_6Mo^{V}_4Mo^{VI}_{14}O_{73}]^{10-}$. Furthermore, each Mo center on the γ-$\{P_2Mo_{14}\}$ unit contains just one Mo=O bond, whereas every Mo center on the "handle" $\{P_4Mo_4\}$ fragments possesses two Mo=O bonds, which suggests that the Mo centers on the γ-$\{P_2Mo_{14}\}$ unit are more easily reduced and that all four electrons could be delocalized only on the γ-$\{P_2Mo_{14}\}$ unit.[20a]

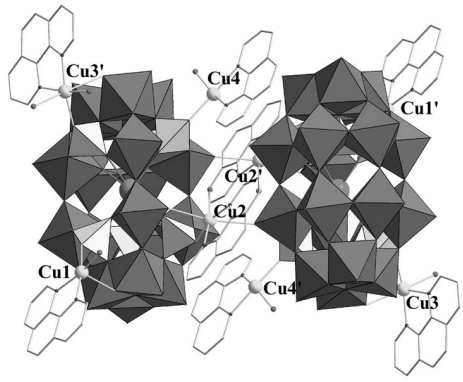

Figure 4. Polyhedral and ball-and-stick representation of the dimeric cluster of **1** and the coordination environments of the Cu centers. The isolated $\{Cu5(phen)(H_2O)_3\}$ unit is omitted for clarity. Octahedron, Mo; tetrahedron, P; large black ball, Sr; middle grey ball, Cu; small black ball, O; grey line, phen group.

## XPS, UV/Vis, and IR Spectral Analyses

The oxidation states of Mo, Sr, and Cu in **1** are further confirmed by XPS measurements. The XPS spectrum of molybdenum indicates two overlapped peaks of $Mo^{6+}$ and $Mo^{5+}$ ions in the energy region of $Mo3d_{5/2}$ and $Mo3d_{3/2}$ (Figure 5a).[21a] The peaks of $Mo3d_{5/2}$ at 232.3 and 230.9 eV

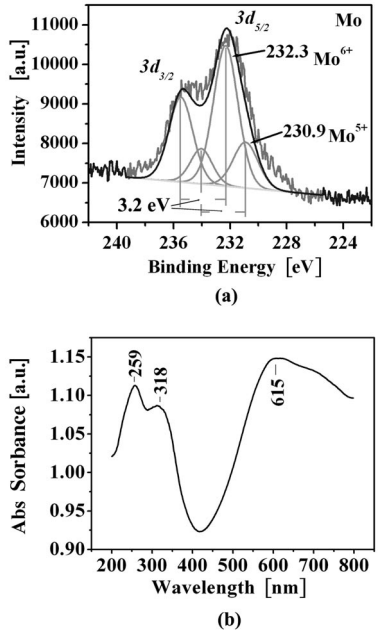

Figure 5. (a) The XPS spectrum of mixed-valent Mo in **1**. The fit line (black smooth line on the top) is produced by the decomposition of the overlapping peaks of $Mo^{6+}$ and $Mo^{5+}$ (middle and bottom grey lines) with a peak/area ratio of ca 3.5:1; (b) solid-state UV/Vis spectrum of **1**.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

are attributable to the $Mo^{6+}$ and $Mo^{5+}$ ions, respectively.[21a] The best fit (top black line in Figure 5a) for the XPS spectrum of the mixed-valent Mo compound is produced by decomposition of the overlapping peaks of $Mo^{6+}$ and $Mo^{5+}$ with a peak/area ratio of ca. 3.5:1, which corresponds to the 14 $Mo^{VI}$ and 4 $Mo^{V}$ centers in compound **1**. This result is consistent with the BVS calculation and the charge-balance consideration. The XPS measurements were also carried out in the energy region of $Sr3d_{5/2}$ and $Cu2p_{3/2}$, respectively. The peaks at 133.2 eV and 932.4 eV are ascribed to $Sr^{2+}$ and $Cu^{2+}$ ions, respectively (Figure S6).[21b,21c]

The diffuse reflectance UV/Vis spectrum of compound **1** was also investigated with the solid-state sample in $BaSO_4$ pellet (Figure 5b). The two peaks at 259 and 318 nm are associated with two kinds of O–Mo LMCT bands,[20a] whereas the other strong wide band around 615 nm is due to overlap of several bands of the intervalence transition from $Mo^{V}$ to $Mo^{VI}$ by the Mo–O–Mo bond, the d–d transitions of $Mo^{V}$ octahedra,[20a] and the Cu–$N_{(phen)}$ and Cu–$O_{(POM)}$ LMCT bands,[20b] which leads to the dark blue coloration of this compound.

In the IR spectrum of compound **1** (Figure S7), the characteristic peaks concerned with coordinated *o*-phenanthroline are at 1598(m), 1509(m), and 1430(s) $cm^{-1}$. Peaks at 1086(s) and 1025(w) $cm^{-1}$ are assigned to the P–O vibrations and those at 923(s), 840(s), 769(s), and 711 $cm^{-1}$ are attributed to the Mo=O and Mo–O–Mo vibrations of the polyoxoanion cluster.[20a]

## Magnetic Properties

Solid-state variable-temperature magnetic susceptibility measurements were performed on the polycrystalline samples of **1** suspended in eicosane to prevent torquing. The DC magnetic susceptibility ($\chi_M$) data were measured in the temperature range 1.8–300 K in a 1 T magnetic field and are plotted as $\chi_M T$ versus $T$ in Figure 6. For **1**, the $\chi_M T$ product of 1.97 $cm^3 K mol^{-1}$ at 300 K decreases continuously to 1.92 $cm^3 K mol^{-1}$ at 1.8 K. The $\chi_M T$ value at room temperature is much lower than the spin-only value ($g$ = 2.0) of 3.375 $cm^3 K mol^{-1}$ for five $Cu^{2+}$ and four $Mo^{5+}$ noninteracting ions ($S$ = 1/2), but close to the value of 1.875 $cm^3 K mol^{-1}$ for five isolated $Cu^{2+}$ ions. This result suggests that four delocalized electrons in each polyoxoanion cluster might be totally antiferromagnetically coupled, which has yet to be observed.[22] The $1/\chi_M$ versus $T$ curve is consistent with the Curie–Weiss law with $C$ = 1.98 $cm^3 K mol^{-1}$ and $\theta$ = –0.1 K, which indicates the presence of very weak antiferromagnetic interactions in the whole compound.

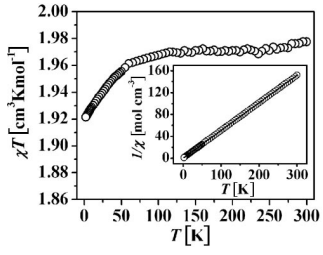

Figure 6. $\chi_M T$ vs. $T$ curve of **1**; inset: $1/\chi_M$ vs. $T$ curve. The solid line is the fitted result based the on Curie–Weiss law.

## Thermogravimetric (TG) Analysis

The thermal behavior of compound **1** was investigated between 50 and 930 °C. The TG curve of this compound presents a three-step weight-loss process (Figure S8). The first step in the temperature range 80–300 °C corresponds to the loss of isolated and coordinated water molecules (calcd. weight loss 4.32%; found 4.43%). The second step occurs between 400 and 600 °C and corresponds to the loss of the *o*-phenanthroline ligands on copper centers (calcd. weight loss 19.65%; found 20.94%). The third step in the temperature range 760–930 °C is probably due to the evaporation of $P_2O_5$ (calcd. weight loss 18.57%; found 17.10%). The result of the TG analysis basically agrees with that of the structure determination.

## Electrochemical and Electrocatalytic Properties

Although compound **1** was obtained from an aqueous system, it cannot be dissolved in water or a weak acidic aqueous solution. Therefore, its electrochemical behavior was investigated with a **1**-modified carbon paste electrode (**1**-CPE).[23] The cyclic voltammetric behavior for **1**-CPE in 1-M $H_2SO_4$ aqueous solution at different scan rates were recorded (Figure S9a) and they exhibit three reversible redox peaks in the potential range +800 to –100 mV, which is attributable to the $[Sr{\subset}P_6Mo_{18}O_{73}]^{10-}$ polyanions. At scan rates lower than 100 $mV s^{-1}$, the peak currents were proportional to the scan rate (Figure S9b), which indicates that the redox process of **1**-CPE is surface controlled. It is noteworthy that **1**-CPE possesses high stability. When the potential range is maintained at +800 to –100 mV, the peak currents almost remain unchanged over 300 cycles at a scan rate of 100 $mV s^{-1}$. After **1**-CPE was stored at room temperature for one month, the peak current decreased by only 3% and could be renewed by squeezing a little carbon paste out of the tube. The high stability of **1**-CPE could be ascribed to the organic–inorganic hybrid structural feature of **1** that stabilizes the polyoxoanion in the compound. Further, compound **1** is insoluble in the acidic aqueous media used in this experiment, which avoids the loss of the modifier during measurements. Thus, **1**-CPE could be an ideal electrode material to investigate electrocatalytic properties. Actually, **1**-CPE displays good electrocatalytic activity towards the reduction of hydrogen peroxide (Figure 7). At the **1**-CPE, with the addition of $H_2O_2$, all three reduction peak currents increased, whereas the corresponding oxidation peak currents dramatically decreased, which suggests that $H_2O_2$ was electrocatalytically reduced by all three reduced polyoxoanion species.[23,24] Furthermore, the cata-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

lytic activities were enhanced with the increasing extent of the anion reduction. In contrast, the reduction of $H_2O_2$ at a bare electrode generally requires a large overpotential and no obvious response was observed at a bare CPE.

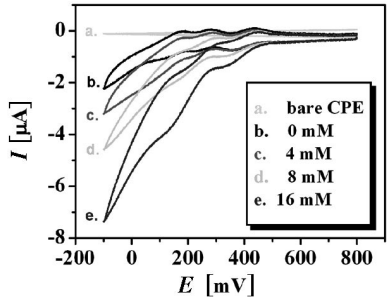

Figure 7. Cyclic voltammograms of **1**-CPE in $H_2SO_4$ (1 M) containing 0.0, 4.0, 8.0, and 16.0 mM $H_2O_2$ and a bare CPE in 5.0-mM $H_2O_2$ + 1-M $H_2SO_4$ solution. Potentials vs. SCE. Scan rate: 30 mV s$^{-1}$.

## Conclusions

In this paper, we report organic–inorganic hybrid compound **1**, which exhibits a four-electron-reduced basket-like polyoxoanion modified with four $\{Cu(phen)(H_2O)_x\}$ ($x$ = 1 and 2) fragments. Electrochemical analysis shows that **1**-CPE displays good electrocatalytic activity to reduce hydrogen peroxide. During the preparation of **1**, the use of $Sr^{2+}$ ions led to the successful isolation of this new hybrid compound, which can serve as a basis for a new type of POM building block. Future efforts will be focused on the reactions between various functional organic–metal fragments and the basket-shaped polyoxoanion to obtain more $[Sr\subset P_6Mo_{18}O_{73}]$-based compounds. Furthermore, the templating effect of $Sr^{2+}$ may also play an important role in the formation of $[Sr\subset P_6Mo_{18}O_{73}]^{10-}$; thus, other alkaline earth metal ions such as $Ca^{2+}$ and $Ba^{2+}$ will be introduced into this reaction system to check whether this templating effect could be reproduced.

## Experimental Section

**Materials:** All chemicals purchased were of reagent grade and used without further purification.

**Physical Methods:** Elemental analyses (C, H, N) were performed with a Perkin–Elmer 2400 CHN elemental analyzer. Mo, Cu, P, and Sr were determined with a Leaman inductively coupled plasma (ICP) spectrometer. IR spectrum was recorded in the range 400–4000 cm$^{-1}$ with an Alpha Centaurt FT/IR spectrophotometer with a pressed KBr pellet. Diffuse reflectance UV/Vis spectrum ($BaSO_4$ pellet) was obtained with a Varian Cary 500 UV/Vis NIR spectrometer. X-ray photoelectron spectrum (XPS) analyses were performed with a VG ESCALAB MK II spectrometer with a Mg-$K_\alpha$ (1253.6 eV) achromatic X-ray source. The vacuum inside the analysis chamber was maintained at $6.2\times10^{-6}$ Pa during analysis. Magnetic susceptibility measurements were carried out with the use of a Quantum Design SQUID MPMS-XL susceptometer. DC measurements were conducted from 1.8 to 300 K by using a 1-T field and performed on finely ground polycrystalline samples. The magnetic data were corrected for the diamagnetic contribution calculated from Pascal's constants.[25] TG analysis was performed with a Perkin–Elmer TGA7 instrument in flowing $N_2$ with a heating rate of 10 °C min$^{-1}$. The electrochemical measurement was carried out on a CHI 660 electrochemical workstation at room temperature (25–30 °C).

**1-Modified Carbon Paste Electrode (1-CPE):** Graphite powder (1.0 g) and compound **1** (40 mg) were mixed and ground together with an agate mortar and pestle to achieve an even and dry mixture. Nujol (0.66 mL) was then added to the mixture and stirred with a glass rod. The homogenized mixture was used to pack glass tubes with a 3-mm inner diameter, and the surface was wiped with weighing paper. Electrical contact was established with a copper rod through the back of the electrode. Platinum gauze was used as the counter electrode and an SCE as the reference electrode.

**Compound 1:** A mixture of $Na_2MoO_4{\cdot}2H_2O$ (0.930 g), $CuCl_2{\cdot}2H_2O$ (0.204 g), phen (0.216 g), $H_3PO_4$ (0.838 mL, 85 wt.-%), and $SrCl_2$ (0.317 g) in a molar ratio of 1.00:0.30:0.30:4.80:0.50 was dissolved in $H_2O$ (16 mL) and stirred at room temperature for 30 min. During this period, the pH value of the solution was adjusted to ca. 3.5 with a solution of NaOH (1 M). The final mixture was sealed in a 30-mL Teflon-lined stainless steel reactor and heated at 160 °C for 4 d. The dark-blue crystals were isolated and collected by filtration, washed thoroughly with distilled water, and dried at room temperature. Yield: 65% (based on Mo). $C_{60}H_{62}Cu_5Mo_{18}N_{10}O_{84}P_6Sr$ (4585.26): calcd. C 15.72, H 1.36, N 3.05, P 4.05, Cu 6.93, Mo 37.66, Sr 1.91; found C 15.79, H 1.42, N 3.11, P 3.99, Cu 7.01, Mo 37.69, Sr 1.87.

**X-ray Crystallography:** Single crystal of **1** with the size of $0.27\times0.25\times0.23$ mm was mounted on a glass fiber, and the data were collected with a Bruker SMART CCD diffractometer with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). Semi-empirical absorption correction based on symmetry equivalent reflections was applied. A total of 41645 reflections were collected, of which 19453 reflections were unique [$R$(int) = 0.0516]. The structure was solved by direct methods and refined by the full-matrix least-squares method based on $F^2$. Structure solution, refinement, and generation of publication materials were performed with the use of the SHELXTL crystallographic software package.[26] During the refinement, the [Cu(4)(phen)($H_2O$)] unit is disordered in two

positions with the site occupancies of 44 and 56%, respectively. All non-hydrogen atoms were refined with anisotropic parameters. The H atoms on the C atoms of phen were included in calculated positions with the use of a riding model and refined with fixed isotropic thermal parameters. The H atoms on water molecules were not included and just put into the final molecular formula. The largest residual peak (2.494 e$Å^{-3}$) is near the phen group but featureless, Q1···C46 0.583 Å. The deepest hole is –1.737 e$Å^{-3}$, which is close to the Mo8 atom. A summary of the crystal data is presented in Table 2. Atomic coordinates and isotropic displacement parameters for **1** are listed in Table S1, and selected bond lengths and angles are listed in Table S2. CCDC-642168 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see footnote on the first page of this article): Additional structural figures and packing arrangement views of **1**, additional XPS spectra, IR spectrum, TG curve, and CV analyses for compound **1**.

# Synthesis and Magnetic Study of $\mu_{1,1}$-Azido-Bridged Dinuclear Manganese(II) Complexes Based on Tripyridyl Ligands

**Ming-Ming Yu,[a] Zhong-Hai Ni,[a] Chong-Chao Zhao,[a] Ai-Li Cui,[a] and Hui-Zhong Kou*[a]**

**Keywords:** Manganese / Dinuclear complexes / Crystal structures / Magnetic properties / Azido bridge

Three azido-bridged $Mn^{II}$ complexes of formulas $[Mn_2(N_3)_4(ttp)_2]$ (**1**), $[Mn_2(N_3)_4(ttp\text{-}N_3)_2]$ (**2**) and $[Mn_2(N_3)_4(ttp\text{-}N_3)_2]_3[Mn^{III}(ttp\text{-}N_3)(N_3)_3]_2$ (**3**), where ttp and ttp-$N_3$ represent 4′-*p*-tolyl-2,2′:6′,2′′-terpyridine and 4′-*p*-azidomethylphenyl-2,2′:6′,2′′-terpyridine, were synthesized and characterized by single-crystal X-ray diffraction analysis and magnetic studies. The Mn ions in complexes **1** and **2** are coordinated by three N atoms of the ttp or ttp-$N_3$ ligands, and they are connected by double end-on (EO) azide ligands; this forms a dinuclear $Mn^{II}$ system with Mn–N–Mn bridging angles of 103.5 and 103.1°. The Br atoms of the $–CH_2Br$ ligands were replaced by azido groups during the formation of complexes **2** and **3**. The structure of complex **3** comprises two structurally similar $Mn^{II}$ dimers with double end-on bridging azide groups and one mononuclear $Mn^{III}$ structure. The bridging Mn–N–Mn angles in **3** are 104.2, 105.1, and 106.73°. Magnetic studies indicate the presence of intramolecular ferromagnetic superexchange. The strength of ferromagnetic coupling within the $Mn_2$ cores in **1**–**3** is dependent on the Mn–N–Mn bridging angles. The magnetic coupling constants for intermolecular exchange are 2.46(4), 2.25(2), and 1.92(4) $cm^{-1}$ for **1**, **2**, and **3**, respectively, on the basis of Hamiltonian $\hat{H} = -2J\hat{S}_1\hat{S}_2$.

## Introduction

During the last two decades chemists have been interested in the azido ligand for its versatile coordination modes and remarkable ability to transmit ferro- or antiferromagnetic interactions.[1] The azido ligand is able to bridge metal ions in several forms, including the usual μ-1,1 (end-on, EO) or μ-1,3 (end-to-end, EE) mode[2] and the unusual μ-1,1,3, μ-1,1,1, μ-1,1,1,1, μ-1,1,3,3 or μ-1,1,1,3,3,3 modes.[3–6] EE bridging usually transmits antiferromagnetic interactions between the metallic centers, whereas EO bridging is known to transmit ferromagnetic interactions irrespective of what metal ions are involved.[7] The theory of spin polarization developed by Kahn et al.[8] has been used to interpret the magnetic interaction through the azido group in $Cu^{II}$, $Ni^{II}$, and $Mn^{II}$ systems.[9] Many studies concerning the ferromagnetic interactions in $Cu^{II}$ and $Ni^{II}$ end-on azido systems have been carried out extensively, and structure parameters, especially bridging angle, were found to be the main factors controlling the strength of the ferromagnetic interaction.[10–13] For $Mn^{II}$ systems with only end-on azido bridges, examples are limited.[14,15] Recently, Aromí et al. found that there is a linear relationship between the exchange coupling constant ($J$) and the Mn–N–Mn bridging angle ($\theta$) on the basis of results obtained for only four complexes.[15a] We then prepared a series of end-on azido-bridged $Mn^{II}$ complexes with the $[Mn_2(phen)_4(N_3)_2]^{2+}$ core and improved the $J$–$\theta$ relationship.[15b] Apparently, more effort should be exerted to make the assumption of the relation of $J$ and $\theta$ more clear. Herein, we describe the syntheses, structures, and magnetic properties of three dinuclear $Mn^{II}$ compounds with tridentate 4′-*p*-tolyl-2,2′:6′,2′′-terpyridine (ttp) and 4′-*p*-bromomethylphenyl-2,2′:6′,2′′-terpyridine (ttp-Br) ligands. Interestingly, the Br atoms in the ttp-Br ligands were replaced by azido groups to give the new 4′-*p*-azidomethylphenyl-2,2′:6′,2′′-terpyridine (ttp-$N_3$) ligand, which then goes on to form complexes $[Mn_2(N_3)_4(ttp\text{-}N_3)_2]$ (**2**) and $[Mn_2(N_3)_4(ttp\text{-}N_3)_2]_3[Mn(ttp\text{-}N_3)(N_3)_3]_2$ (**3**). The bridging Mn–N–Mn angle of complex **3** is the largest hitherto found in double EO azido-bridged dimeric $Mn^{II}$ complexes.

## Results and Discussion

### Synthesis and General Characterization

Tridentate ttp-type ligands are analogous to the commonly used 2,2′:6′,2′′-terpyridine (terpy) ligand. Previously, Rojo et al. reported an end-on azide-bridged $Mn^{II}$ dimer $[Mn_2(terpy)_2(\mu_{1,1}\text{-}N_3)_2(N_3)_2]\cdot 2H_2O$.[14a] This complex has a bridging Mn–N–Mn angle of 104.6°, which is the

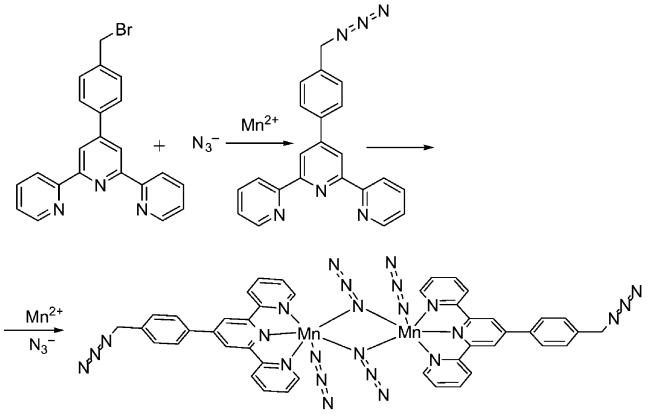
largest among the reported EO azido-bridged dimeric $Mn^{II}$ complexes. In this work, we used ttp-type ligands in the hope of obtaining similar dimeric complexes. Complexes **1**–**3** were prepared and characterized. They have EO azido-bridged dimeric structures that are similar to $[Mn_2(terpy)_2(\mu_{1,1}\text{-}N_3)_2(N_3)_2]\cdot 2H_2O$.[14a] Interestingly, a 1D polymeric $Mn^{II}$ complex, $[Mn(tptz)(\mu_{1,1}\text{-}N_3)_2]_n$[16] [tptz = 2,4,6-tris(2-pyridyl)-1,3,5-triazine], was synthesized with the tptz ligand that is similar to ttp. During the preparation of complexes **2** and **3**, ttp-$N_3$ formed in situ by substitution of the bromo group by an azido group (Scheme 1). In organic synthesis, sodium azide is often used as a reactant to substitute bromoalkyl groups.[17] However, the substitution reaction of an azido group accompanied by crystallization of metallic complexes is rare. It is known that azide can stabilize divalent transition-metal ions when neutral pyridyl reagents are used as auxiliary ligands. We found that tripyridyl $Mn^{II}$ can be slowly oxidized by oxygen dissolved in the solvent. The exposure to light accelerates the oxidation process. The formed neutral $[Mn(ttp\text{-}N_3)(N_3)_3]$ monomer cocrystallized with the $Mn^{II}$ dimer in **3**.



Scheme 1. Possible formation mechanism of ttp-$N_3$ and complex **2**.

The IR spectra of three complexes show a strong peak at ca. 1600 $cm^{-1}$, which is assigned to the C=N stretching vibration in the pyridine rings of the ligands. The $\nu_{asym}(N_3^-)$ mode of complexes **1**–**3** appear at ca. 2000–2100 $cm^{-1}$. The splitting of the signals indicates the presence of both bridging and terminal azide ligands. The peaks at 2093 $cm^{-1}$ for complex **2** and 2086 $cm^{-1}$ for complex **3** should be assigned to the alkyl azido asymmetric stretching vibration.[17] The peak at 2037 $cm^{-1}$ for complex **3** may be due to the $\nu_{asym}(N_3^-)$ mode of the $[Mn^{III}(ttp\text{-}N_3)(N_3)_3]$ moiety by considering that the $[Mn^{III}(terpy)(N_3)_3]$ analog exhibits a strong band at 2035 $cm^{-1}$.[18] In addition, azido complexes are expected to show $\nu_{sym}(N_3^-)$ and deformation mode $\delta(N_3^-)$ at ca. 1300–1350 and ca. 620 $cm^{-1}$, respectively.[18] For complexes **1**–**3**, only the symmetric azide stretching vibration was observed as a medium signal.

Complexes **1**, **2**, and **3** are slightly soluble in MeCN, but they are not soluble in alcohol solvents. The electronic spectra of compounds **2** and **3** in MeCN are similar and a shoulder band at 400–450 nm is apparent; this shoulder is responsible for the color of the compounds. The spectrum of **1** in MeCN shows no apparent absorption in the visible region, which is consistent with the light color of the complex. Relative to the spectra of the ttp and ttp-Br ligands, the UV absorptions related to the n–π* or π–π* transitions within the ligands show an obvious redshift, which is due to better planarity of the tripyridyl group accompanied by chelation to $Mn^{II}$ ions (see the Supporting Information).

## Crystal Structure of Complexes 1, 2, and 3

Crystal data are summarized in Table 1. Selected bond lengths and angles of complexes **1**, **2**, and **3** are included in Table 2. ORTEP representations of the crystallographic molecular structure of complexes **1**, **2**, and **3** are shown in Figures 1, 2, and 3.

Complexes **1** and **2** exhibit centrosymmetric dimers $[Mn(N_3)_2(ttp)]_2$ or $[Mn(N_3)_2(ttp\text{-}N_3)]_2$, respectively. The $Mn^{II}$ ions in complexes **1** and **2** are linked by double end-on bridging azide groups. The other two azide moieties act as terminal ligands. In complex **1**, each Mn ion exhibits a slightly distorted octahedral coordination sphere and the three nitrogen atoms of the terpy ligand [Mn1–N1: 2.269(1) Å, Mn1–N2: 2.224(1) Å, Mn1–N3: 2.279(2) Å] and the nitrogen atom of one bridging azide group [Mn1–N4A: 2.127(1) Å (A: 2 –*x*, – y, 1 – *z*)] form the equatorial plane. The nitrogen atom of one terminal azido group [Mn1–N7: 2.153(2) Å] and the nitrogen atom of the second bridging group [Mn1–N4: 2.363(2) Å] are situated in the axial positions. The existence of an inversion center causes the Mn–N4–Mn1A–N4A bridging unit to form a plane. In this dimeric unit, the Mn cations are separated from each other by 3.528(4) Å. The bridging Mn–N4–Mn1A angle is 103.5°. The bridging and terminal azido ligands are quasilinear and the N4–N5–N6 and N7–N8–N9 angles measure 177.03 and 178.22°, respectively.

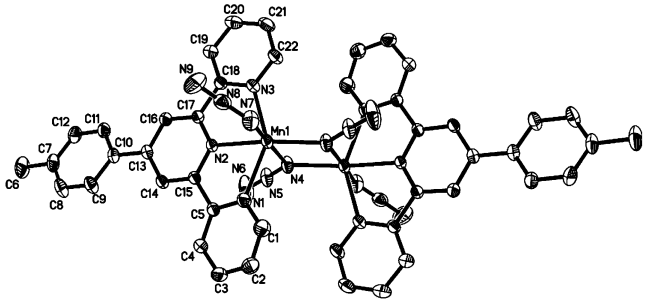

Figure 1. Crystal structure of complex **1**.

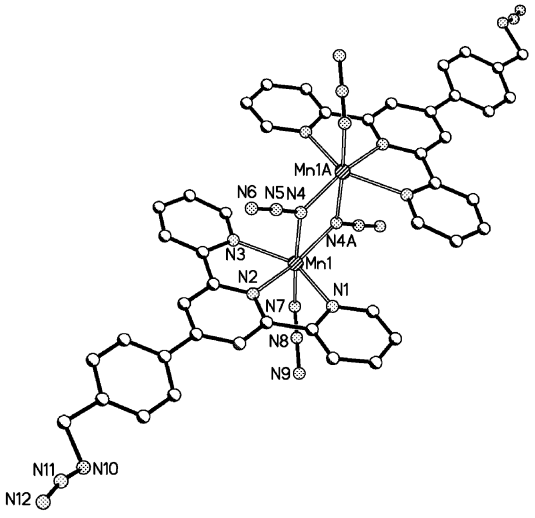

Figure 2. Crystal structure of complex **2**.

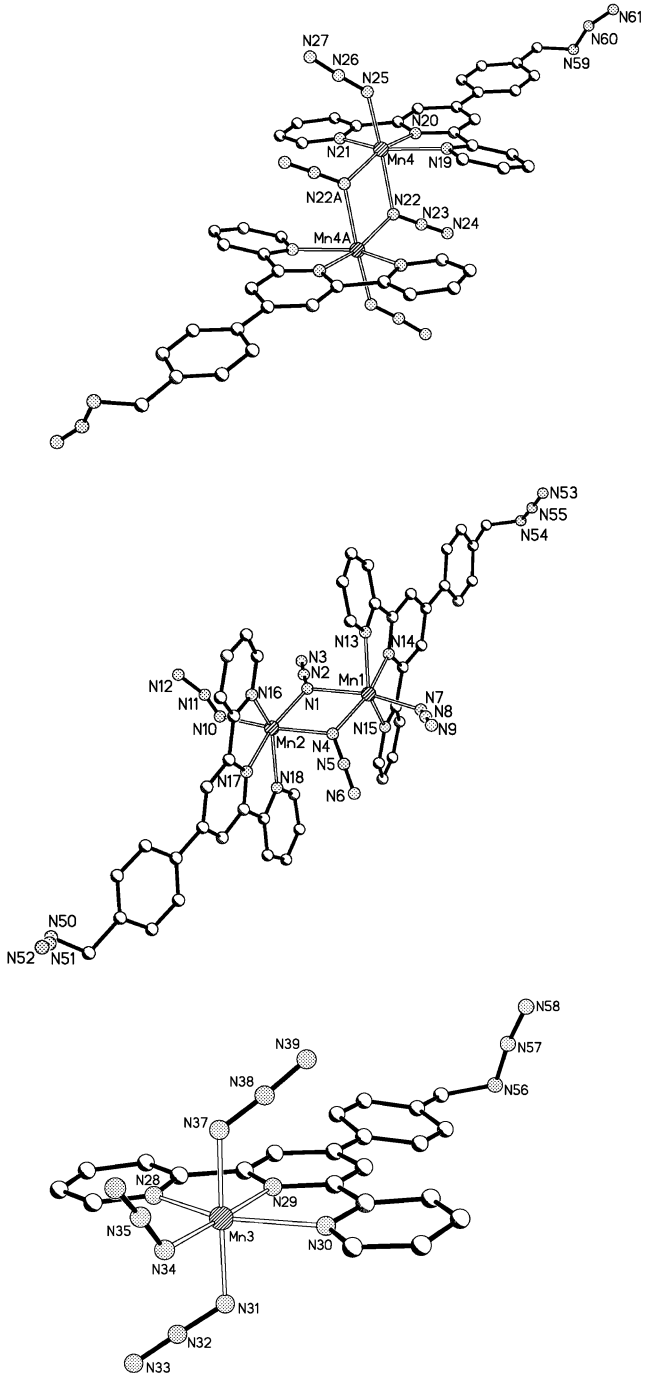

Figure 3. Crystal structure of complex **3** showing three cocrystallized moieties.

In complex **2**, each Mn cation exhibits a distorted octahedral coordination sphere and the Mn–N bond lengths range from 2.126(3) Å [Mn1–N4A (A: 1 –*x*, 1 – *y*, 1 – *z*)] to 2.378(2) Å (Mn1–N4). In this dimeric unit, the Mn cations are separated from each other by 3.532(4) Å with a bridging Mn–N4–Mn1A angle of 103.1°. The bridging and terminal azido ligands are quasilinear [177.29 and 179.90°].

The structure of complex **3** comprises three doubly end-on azide-bridged $Mn^{II}$ dimers and two $Mn^{III}$ monomers. One dimer exhibits a centrosymmetric structure and the

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

other is asymmetric. The dimeric structure is very similar to that of complexes **1** and **2**. In the asymmetric dimer comprised of Mn1 and Mn2, the nitrogen atoms of one terminal azido group [Mn1–N7: 2.135(3) Å] and one bridging group [Mn1–N1: 2.331(3) Å] are situated in the axial positions. The intradimer Mn1···Mn2 distance is 3.569(6) Å, and the bridging Mn1–N1–Mn2 and Mn1–N4–Mn2 bond angles are 104.2 and 106.73°, respectively. In the inversion center related unit, the Mn–N distances are in the range 2.138(4) (Mn4–N25) to 2.341(3) Å (Mn4–N22). In this dimeric unit, the Mn cations are separated from each other by 3.562(3) Å. The bridging azides slightly deviate (up and down) from that plane and the bridging Mn–N4–Mn1A angle is 105.1°. In the neutral $Mn^{III}$ monomer Mn(ttp-$N_3$)$(N_3)_3$, the Mn–N bond lengths range from 1.951(3) to 2.248(3) Å, which is consistent with a $Mn^{III}$ ion with a Jahn–Teller effect for the $d^4$ electronic configuration. The bond lengths and coordination geometry are very similar to those of [Mn(terpy)$(N_3)_3$].[18]

### Magnetic Behavior of Complexes 1, 2, and 3

The $\chi_m T$ vs. $T$ plots (2–300 K) of complexes **1**, **2**, and **3** are shown in Figures 4, 5, and 6, respectively. At 300 K, the $\chi_m T$ values per dimer are 8.762 and 8.904 emu K mol$^{-1}$ for **1** and **2**, respectively, which are both close to the expected value (8.75 emu K mol$^{-1}$) for two uncoupled spin $S_{Mn}$ = 5/2 systems. With decreasing temperature, $\chi_m T$ increases sharply to reach a maximum value of 6.43 emu K mol$^{-1}$ at 8 K for complex **1** and 14.34 emu K mol$^{-1}$ at 9 K for complex **2**; it then decreases because of weak intermolecular antiferromagnetic interaction and/or zero-field splitting of the ground spin state of $S$ = 5. Magnetic susceptibility could be fit to a Curie–Weiss law with Curie constant $C$ = 8.96 emu K mol$^{-1}$ and a positive Weiss constant $\theta$ = 8.68 K for complex **1** and $C$ = 4.08 emu K mol$^{-1}$ and $\theta$ = 7.89 K for complex **2**. These results indicate that the overall magnetic behavior of **1** and **2** is ferromagnetic, which should be attributed to the dinuclear superexchange mediated through the $\mu_{1,1}$-azido bridges. The expression for the magnetic susceptibility ($\chi_d$) of a $Mn^{II}$ dimer derived from Van Vleck's equation (the spin Hamiltonian $\hat{H} = -2J\hat{S}_{Mn1}\hat{S}_{Mn2}$) is expressed in Equation (1), in which $A$ = 55 + 30exp(–10$J$/$kT$) + 14exp(–18$J$/$kT$) + 5exp(–24$J$/$kT$) + exp(–28$J$/$kT$) and $B$= 11 + 9exp(–10$J$/$kT$) + 7exp(–18$J$/$kT$) + 5exp(–24$J$/$kT$) + 3exp(–28$J$/$kT$) + exp(–30$J$/$kT$).

$$\chi_d = \frac{2Ng^2\beta^2}{kT}\frac{A}{B} \quad (1)$$

Considering weak intermolecular antiferromagnetic coupling, the final molar magnetic susceptibility takes the form of Equation (2), where z$J'$ is the interaction between molecules, and the $N$, $g$, $\beta$, and $\theta$ parameters have their usual meaning.

$$\chi_M = \frac{\chi_d}{1-\chi_d(2zJ'/Ng^2\beta^2)} \quad (2)$$

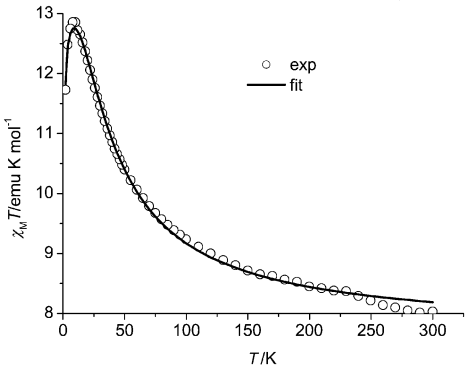

Figure 4. $\chi_m T$ vs. $T$ plot for complex **1**. The solid line represents the best fit.

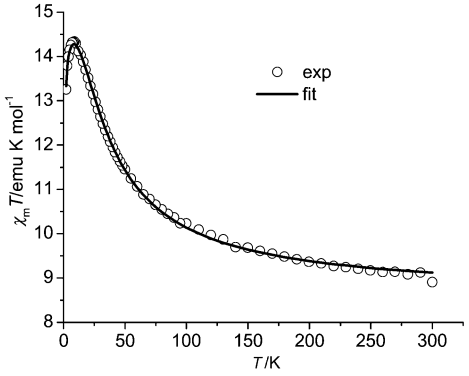

Figure 5. $\chi_m T$ vs. $T$ plot for complex **2**. The solid line represents the best fit.

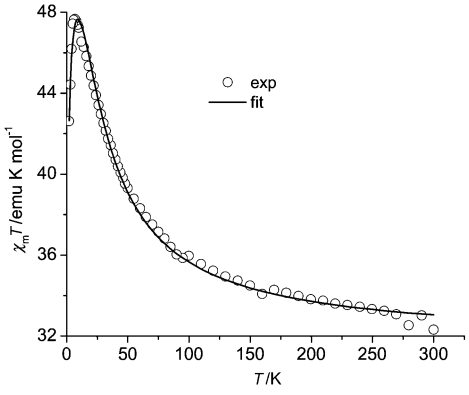

Figure 6. $\chi_m T$ vs. $T$ plot for complex **3**. The solid line represents the best fit.

The best-fit parameters obtained are $J$ = 2.46(4) cm$^{-1}$, $g$ = 1.99(1), and $zJ'$ = –0.0078 cm$^{-1}$ with an agreement factor of $R = \Sigma(\chi_{obsd}T - \chi_{cald}T)^2/\Sigma(\chi_{obsd}T)^2 = 4.24 \times 10^{-5}$ for complex **1** and $J$ = 2.25(2) cm$^{-1}$, $g$ = 1.98(1), $zJ'$ = –0.0072(3) cm$^{-1}$ and $R = 2.03 \times 10^{-5}$ for complex **2**.

The decrease in $\chi_m T$ at low temperature could be alternatively interpreted by the presence of zero-field splitting (ZFS) of the spin ground state $S_T$ = 5. The data were fit to a model that includes the energy splitting of the ground spin state. By using a modified term of the Heisenberg spin Hamiltonian of a dinuclear system ($\hat{H} = -2J\hat{S}_1\hat{S}_2$) as $\hat{H}_{ZFS}$

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

$= D[\hat{S}_{Tz}^2 - S_T(S_T+1)/3]$, the expression for the magnetic susceptibility of ferromagnetically coupled $Mn^{II}$ dimer is depicted in Equation (3),[15c] where $A = 6\exp(9D/kT) + 24\exp(6D/kT)+54\exp(D/kT) + 96\exp(-6D/kT) + 150\exp(-15D/kT) + 180\exp(-10J/kT) + 84\exp(-18J/kT) + 30\exp(-24J/kT) + 6\exp(-28J/kT)$, $B = \exp(10D/kT) + 2\exp(9D/kT) + 2\exp(6D/kT) +2\exp(D/kT) + \exp(-6D/kT) + 2\exp(-15D/kT) + 9\exp(-10J/kT) + 7\exp(-18J/kT) + 5\exp(-24J/kT) + 3\exp(-28J/kT) +\exp(-30J/kT)$.

$$\chi_M = \frac{Ng^2\beta^2}{3kT}\frac{A}{B} \quad (3)$$

The least-square fit of the experimental data to the above expression gives the following parameters: $J = 2.46(2)\ cm^{-1}$, $g = 1.99(1)$, $D = 0.019(1)\ cm^{-1}$, and $R = 4.10\times10^{-5}$ for complex **1** and $J = 2.26(2)\ cm^{-1}$, $g = 1.98(1)$, $D = 0.017(1)\ cm^{-1}$, and $R = 2.02\times10^{-5}$ for complex **2**.

The best-fit results including intermolecular interaction or zero-field splitting are very similar. Both effects are likely operative with similar strength, and it is impossible to distinguish between them.[15c]

At 300 K, the $\chi_m T$ value of complex **3** is ca. 33.0 emu K $mol^{-1}$, which is close to that (32.25 emu K $mol^{-1}$) expected for an uncoupled system ($6Mn^{II} + 2Mn^{III}$). With a decrease in the temperature, the $\chi_m T$ values increase sharply to reach a maximum value of 47.66 emu K $mol^{-1}$ at 7 K, and then they decreases to 42.62 emu K $mol^{-1}$ at 2 K due to weak antiferromagnetic interaction and/or zero-field splitting. These results indicate that the overall behavior of **3** corresponds to a ferromagnetic interaction, which should be attributed to the dinuclear superexchange mediated through the $\mu_{1,1}$-azido bridges. Magnetic susceptibility could be fit to a Curie–Weiss law with Curie constant $C =$ 32.57 emu K $mol^{-1}$ and a positive Weiss constant $\theta =$ 6.25 K. The positive $\theta$ value and the shape of the $\chi_m T$ curves for **3** indicate the existence of ferromagnetic interactions between double EO azido-bridged $Mn^{II}$ ions.

Taking the contributions of intermolecular interaction and the $Mn^{III}$ monomers into account and using one $J$ value for simplicity, the final molar magnetic susceptibility is in the form of Equation (4), where $\chi_{dimer}$ is the expression including both $J$ and $zJ'$ for complexes **1** and **2**.

$$\chi_M = 3\chi_{dimer} + \frac{4Ng^2\beta^2}{kT} \quad (4)$$

The least-square fit of the experimental data gives the following parameters: $J = 1.92(4)\ cm^{-1}$, $g = 1.98(1)$, $zJ' = -0.0019(4)\ cm^{-1}$, and $R = 5.47\times10^{-5}$ for complex **3**.

Field dependence of the magnetization at 2 K of complexes **1**, **2**, and **3** are shown in the Supporting Information. Experimental data fit well to the Brillouin function value for $S = 5$, and are well above that for two noncoupling $S =$ 5/2 $Mn^{II}$ ions, which indicates the existence of ferromagnetic interactions between double EO azido-bridged $Mn^{II}$ ions. For complex **3**, the $Mn^{III}$ monomers ($S_{Mn^{III}} = 2$) should be included when calculating the Brillouin curve, that is, $S = 5\times3 + 2\times2$ and noninteracting $S = 6\times5/2 + 2\times2$, respectively. The experimental data for **3** are above the Brillouin curve for $S = 6\times5/2 + 2\times2$ at low magnetic field (<20 kOe), and they are below that for $S = 5\times3 + 2\times2$. The discrepancy in **3** compared with complexes **1** and **2** is assigned to the presence of $Mn^{III}$ ions, and it is usually difficult to reach magnetic saturation because of magnetic anisotropy.[19]

The above results could be interpreted by the theoretical point of view for dinuclear complexes by using the spin-polarization model and hybrid density functional theory (DFT). Kahn et al. first explained the ferromagnetic interactions between EO azido-bridged dinuclear complexes on the basis of the spin-polarization effect. This model considers that the electron of a bridging nitrogen atom (α spin) of the in-plane $\pi_g$ orbital (HOMO) is partially delocalized toward the two metal orbitals; the unpaired electrons occupying the orbitals are likely to have β spins, which favors ferromagnetic interactions. The interaction through the

azido bridge does not depend on the surroundings of the metal ions but only on the fashion of azido bridges.[9] DFT calculations show that the value of $J$ is mainly dependent on the energy gap between the molecular orbitals associated with the unpaired electrons (SOMOs). Aromí et al. recently gave a rough relationship between the exchange coupling constant ($J$) and the Mn–N–Mn bridging angle ($\theta$), which was afterwards improved to $J = 0.614\theta - 61.9$ on the basis of eight complexes.[15a,15b] The magnet data of this work and available EO azido-bridged dinuclear complexes are in good agreement with the fact that the exchange coupling constant increase with the Mn–N–Mn bridging angle (Table 3), which is consistent with theoretical predictions.[9a] The $J$–$\theta$ relationship can be now improved on the basis of 15 data sets listed in Table 3 to give the equation $J = 0.276\theta - 26.9$, as shown in Figure 7. In addition, an increase in the asymmetry of the azido bridging ($\Delta d$ in Table 3) was shown to bring about a decrease in antiferromagnetic interactions ($J_{AF}$), and consequently an increase in the global magnetic exchange constant ($J = J_{AF} + J_F$).[14a] Careful examination of the data in Table 3 shows that the $J$ values for the dimeric complexes generally increase with an increase in $\Delta d$, which is in agreement with the above prediction.

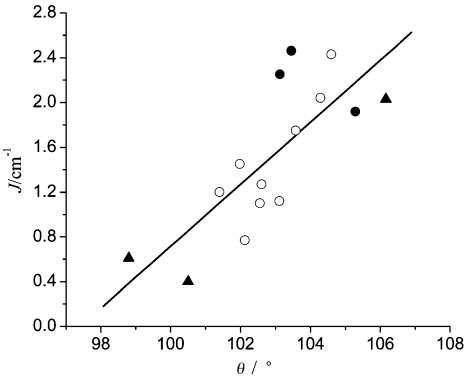

Figure 7. Plot of $J$ vs. Mn–N–Mn bond angle ($\theta$) for EO azido-bridged $Mn^{II}$ compounds (● this work, ▲ 1D complexes). The straight line represents the best fit.

## Conclusions

We successfully prepared three doubly EO azido-bridged dinuclear $Mn^{II}$ complexes. The ferromagnetic properties of dinuclear superexchange mediated through the $\mu_{1,1}$-azido bridges were confirmed in all complexes. Consideration of the intermolecular antiferromagnetic coupling of $Mn^{II}$ or the presence of zero-field splitting (ZFS) of the molecular spin ground state allows the magnetic coupling constants to be evaluated. On the basis of the results of this work and the available $\mu_{1,1}$-azido-bridged $Mn^{II}$ complexes, a clearer magnetostructural correlation was reached.

## Experimental Section

**Materials:** 4′-*p*-Tolyl-2,2′:6′,2′′-terpyridine (ttp) and 4′-(*p*-bromomethylphenyl)-2,2′:6′,2′′-terpyridine (ttp-Br) were prepared as previously reported.[21] All other reagents were commercial grade materials and used as received.

**Measurements:** Elemental analyses were determined with an Elementar Vario EL elemental analyzer. IR spectra were measured as KBr pellets with a Magna-IR 750 spectrophotometer in the 4000–400 $cm^{-1}$ region. Variable-temperature magnetic susceptibility was measured with a SQUID magnetometer with an applied magnetic field of 2000 Oe for **1**, **2**, and **3**.

***Caution!*** *Perchlorate and azide salts are potentially explosive and should be handled carefully in small amounts.*

**4′-*p*-Tolyl-2,2′:6′,2′′-terpyridine (ttp):** Yield: 8%. $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 8.73 (s, 2 H), 8.69–8.60 (m, 4 H), 7.89–7.80 (m, 4 H), 7.51 (d, $J$ = 6.3 Hz, 2 H), 7.32 (ddd, $J$ = 7.2, 4.6, 1.2 Hz, 2 H), 2.45 (s, 3 H) ppm. $C_{22}H_{17}N_3$ (323.40): calcd. C 81.71, H 5.30, N 12.99; found C 81.53, H 5.47, N 12.50.

**4′-(*p*-Bromomethylphenyl)-2,2′:6′,2′′-terpyridine (ttp-Br):** Yield 85%. $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 8.79 (s, 2 H), 8.76–8.69 (m, 4 H), 7.98–7.89 (m, 4 H), 7.61 (d, $J$ = 6.5 Hz, 2 H), 7.41 (ddd, $J$ = 7.5, 4.8, 1.3 Hz, 2 H) ppm. $C_{23}H_{16}BrN_3$ (414.30): calcd. C 65.68, H 4.01, N 10.44; found C 65.42, H 3.91, N 10.49.

**$[Mn_2(N_3)_4(ttp)_2]$ (1):** An aqueous solution (5 mL) of sodium azide (1.5 mmol) was placed in a tube to which was added a buffer layer of water/methanol (10 mL). A methanol solution (10 mL) of $Mn(ClO_4)_2{\cdot}6H_2O$ (0.5 mmol) and ttp (0.5 mmol) was added to form a third layer. Orange crystals were formed on interdiffusion of the reactants in about 1 week. One suitable crystal was chosen for single-crystal X-ray diffraction. Yield: 80.9 mg (35% based on manganese). IR (KBr): $\tilde{\nu}$ = 2046 (vs) N=N=N, 1607 (vs), 1546 (s), 1546 (s), 1474 (s), 1329 (m), 1015 (m), 821 (m), 790 (m), 733 (w), 686 (w), 660 (w) $cm^{-1}$. $C_{44}H_{34}Mn_2N_{18}$ (924.77): calcd. C 57.15, H 3.71, N 27.26; found C 57.07, H 3.90, N 27.37.

**$[Mn_2(N_3)_4(ttp\text{-}N_3)_2]$ (2):** A solution of $Mn(ClO_4)_2{\cdot}6H_2O$ (0.5 mmol) and ttp-Br (0.5 mmol) in methanol (10 mL) was slowly diffused into an aqueous solution (5 mL) of sodium azide (1.5 mmol) in the dark. After 1 week, well-formed orange single crystals were obtained. Yield: 75.5 mg (30% based on manganese). IR (KBr): $\tilde{\nu}$ = 2093 (vs), 2056 (vs), 1603 (vs), 1569 (s), 1546 (s), 1404 (s), 1347 (m), 1326 (m), 1246 (s), 1199 (w), 1165 (m), 1014 (s), 883 (w), 856 (w), 829 (w), 786 (s), 740 (w), 686 (w), 659 (w) $cm^{-1}$. $C_{44}H_{32}Mn_2N_{24}$ (1006.82): calcd. C 52.49, H 3.20, N 33.39; found C 52.11, H 3.29, N 33.85.

**$[Mn_2(N_3)_4(ttp\text{-}N_3)_2]_3[Mn(ttp\text{-}N_3)(N_3)_3]_2$ (3):** The synthetic method is slightly different from that of **2**. A solution of $Mn(ClO_4)_2{\cdot}6H_2O$ (0.2 mmol) and ttp-Br (0.2 mmol) in methanol (10 mL) was diffused into a solution of sodium azide (1.5 mmol) in water (5 mL). After 4 weeks of exposure to light, red-brown crystals were formed. Yield: 25.7 mg (25% based on manganese). IR (KBr): $\tilde{\nu}$ = 2086 (sh), 2063 (vs), 2037 (vs), 1608 (vs), 1573 (s), 1547 (s), 1477 (s), 1431 (s), 1400 (s), 1326 (m), 1276 (m), 1246 (m), 1164 (m), 1013 (s), 891 (w), 829 (w), 790 (s), 733 (w), 690 (w), 659 (w) $cm^{-1}$. $C_{176}H_{128}Mn_8N_{102}$ (4111.32): calcd. C 51.42, H 3.14, N 34.75; found C 51.40, H 3.25, N 34.48.

**X-ray Structure Determination:** Diffraction data were collected with a Bruker Smart CCD area detector with graphite-monochromated Mo-$K_\alpha$ ($\lambda$ = 0.71073 Å) at room temperature. All calculations were performed by using the SHELXS-97 and SHELXL-97 programs.[22] All structures were solved by direct method and refined by the full-matrix least-squares method on $F^2$ with anisotropic thermal parameters for all non-hydrogen atoms. The hydrogen atoms were located geometrically and refined by using a riding model.

# Novel *gem*-Dithiolato-Bridged Rhodium Hydroformylation Catalysts: Bridging the Gap in Dinuclear Rhodium Thiolate Chemistry

**Marc A. F. Hernandez-Gruel,[a] Gustavo Gracia-Arruego,[a] Angel B. Rivas,[b] Isabel T. Dobrinovitch,[a] Fernando J. Lahoz,[a] Alvaro J. Pardey,[b] Luis A. Oro,*[a] and Jesús J. Pérez-Torrente*[a]**

**Keywords:** Homogeneous catalysis / Hydroformylation / Dinuclear complexes / *gem*-Dithiolato ligands / Rhodium

The direct protonation of the bridging hydroxo ligands in $[Rh(\mu\text{-}OH)(cod)]_2$ by 1,1-dimercaptocyclohexane $[Chxn(SH)_2]$ yields the *gem*-dithiolato-bridged compound $[Rh_2(\mu\text{-}S_2Chxn)(cod)_2]$ (**1**). The dinuclear framework in **1** is supported by a 1,1-cyclohexanedithiolato ligand exhibiting a $1{:}2\kappa^2S,1{:}2\kappa^2S'$ coordination mode. Compound **1** is an active catalyst precursor in the presence of P-donor ligands for the hydroformylation of oct-1-ene under mild conditions of pressure and temperature (100 PSI, 353 K). The best results were obtained with phosphite ligands as modifying ligands. An aldehyde selectivity of 97 %, a regioselectivity towards the linear aldehyde of 81 %, and turnover frequencies of up to 198 $h^{-1}$ were obtained with the catalytic system **1**/$P(OMe)_3$. The dinuclear compound $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PPh_3)_2]$ (**2**) was isolated from the catalytic solutions resulting from the system **1**/$PPh_3$ and was characterized by spectroscopic means and by X-ray diffraction to be the *trans* isomer. The mixed-ligand dinuclear complexes **2** and $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PCy_3)_2]$ (**3**) (Cy = cyclohexyl) were independently prepared by reaction of $Chxn(SH)_2$ with the mononuclear complexes $[Rh(acac)(CO)(PR_3)]$ in the appropriate molar ratio.

## Introduction

Dimetallic complexes can serve as catalysts because the expected cooperation between the metal atoms should result in more active and selective catalysts than monometallic systems.[1] However, fragmentation has been a major problem in polymetallic catalysts and, in spite of the intensive research in this field, the number of active dimetallic catalysts actually operating through a dimetallic mechanism are scarce.[2,3] Stanley and co-workers have demonstrated that the homodimetallic rhodium complex *rac*-$[Rh_2(nbd)_2(et,ph\text{-}P4)]^{2+}$, containing a binucleating tetraphosphane ligand, is a precursor of a highly active and selective catalyst for the hydroformylation of 1-alkenes by a mechanism involving dimetallic cooperation between the two rhodium centers.[3] As evidenced by the Stanley's hydroformylation system, the design of the binucleating ligands is of major importance as the catalytic activity largely depends on the structure of the complex. In particular, the ligands must fulfil the electronic requirements of the active metal centers, impart the appropriate electronic and steric influence on the reactions, and more importantly, produce flexible structures allowing the accommodation of the metal centers in close proximity but preventing it from fragmenting.[4]

In this context, it is well known that dinuclear thiolato-bridged complexes $[Rh(\mu\text{-}SR)(CO)(PR'_3)]_2$ (R = *t*Bu, Ph; R′ = OMe, OPh, Ph) are effective catalysts in the hydroformylation of olefins at moderate pressure and temperature (Figure 1a).[5] However, the dinuclear structure of the active catalytic species has been questioned, as kinetic studies suggested the involvement of mononuclear species.[6] Similarly to the Kalck's systems, fluorothiolato- and aminothiolato-bridged dinuclear rhodium complexes have been described as active precursors for the hydroformylation of alkenes under mild conditions.[7] A step forward in rhodium thiolate chemistry was the preparation by Claver and co-workers of di- and tetranuclear dithiolato rhodium complexes with catalytic activity in the hydroformylation of 1-hexene (Figure 1c).[8,9] Monodentate thiolato-bridging ligands provide flexible structures that support a wide range of bonding and nonbonding metal distances by modification of the hinge angle between the rhodium coordination planes. In contrast, the bridging and chelating coordination mode of the dithiolato ligand results in more rigid dinuclear structures with a possible influence on the catalytic activity. In addition, chirality was introduced at the backbone of the dithiolato ligand, which gives rise to chiral dinuclear complexes that show very good regioselectivities in the hydro-

formylation of styrene, although the observed enantioselectivities were low, indicating that the effect of the presence of a chiral dithiolato ligand is rather small.[10]

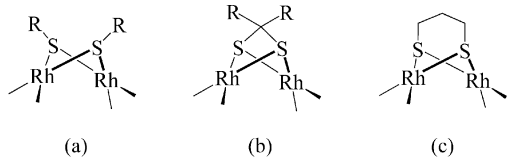

Figure 1. Different thiolato-bridged dinuclear complexes.

The nuclearity of the dithiolato rhodium complexes $[Rh_2(\mu\text{-}S(CH_2)_nS)(L_2)_2]_x$ is influenced both by the number of methylenic units between the two sulfur atoms and by the auxiliary ligands. Tetranuclear diolefin complexes ($L_2$ = cod, $x$ = 2) were generally obtained from dithiolato ligands with large $n$ values (i.e. $n$ = 4). However, the tetranuclear compounds were converted to dinuclear complexes by carbonylation at atmospheric pressure (L = CO, $x$ = 1), which suggests labile Rh–S bonds.[9] In fact, the ion-pair compounds $[Rh(diphos)_2][Rh(dithiolato)(CO)_2]$ were observed in the reaction between a dinuclear carbonyl dithiolato-bridged complex and diphosphanes.[11] In addition, high-pressure spectroscopic techniques (HPNMR and HPIR) have shown that some thiolato- and dithiolato dinuclear rhodium complexes evolve to mononuclear rhodium hydride complexes under hydroformylation conditions.[12]

In order to reinforce the dinuclear framework, we envisaged dinuclear rhodium complexes supported by *gem*-dithiolato ligands (Figure 1b). This type of ligand, although closely related to the standard dithiolato ones, should provide access to new dinuclear complexes with a number of features that could be of interest both in stoichiometric and catalytic reactions. Firstly, the presence of a single bridgehead carbon atom between both sulfur atoms should lead to a more compact $[Rh(\mu\text{-}S_2CR_2)Rh]$ core that is probably more resistant to fragmentation. Secondly, the structure and the coordination mode of the ligand should generate much more rigid dinuclear systems with a likely smaller angle between the coordination planes of the rhodium centers and shorter metal–metal distances, which favor the cooperative effects between the metal centers. Finally, it is important to note that the R groups on the $sp^3$ bridgehead carbon atom are directly oriented toward the rhodium atoms and not toward the center of the dinuclear unit, which could have a determining steric influence on the hydroformylation reaction.

Herein we wish to report on the synthesis of *gem*-dithiolato-bridged dinuclear rhodium complexes and their catalytic activity in the hydroformylation of oct-1-ene. Although a few mono- and dinuclear methanedithiolato and *gem*-dithiolato complexes have been reported,[13] these dinuclear compounds are, to the best of our knowledge, the first example of *gem*-dithiolato complexes directly synthesized from a *gem*-dithiol compound.

## Results and Discussion

The reaction between $[Rh(\mu\text{-}OH)(cod)]_2$ and 1,1-dimercaptocyclohexane $[Chxn(SH)_2]$ in dichloromethane gave a red-orange solution of the compound $[Rh_2(\mu\text{-}S_2Chxn)(cod)_2]$ (**1**), which was isolated as an orange-red microcrystalline solid in good yield (Figure 2). Interestingly, compound **1** can be obtained in similar yields from other di- and mononuclear standard starting materials in rhodium chemisty such as $[Rh(\mu\text{-}OMe)(cod)]_2$ and [Rh(acac)(cod)], although an external base ($NEt_3$) is necessary to drive the reaction to completion. The dinuclear formulation of the complex is supported both by the determination of the molecular weight in chloroform and by the FAB+ spectra that shows the dinuclear ion at $m/z$ = 568. The $^1H$ NMR spectrum in $CDCl_3$ at room temperature shows sharp resonances and is in agreement with the expected rigid framework with $C_{2v}$ symmetry. Thus, two resonances for the olefinic =CH protons and the carbon atoms of the equivalent 1,5-cyclooctadiene ligands were observed in the $^1H$ and $^{13}C\{^1H\}$ NMR spectra, respectively. The protons of the 1,1-cyclohexylene fragment display three resonances, which indicates a rapid equilibrium between the possible chair conformations at room temperature.

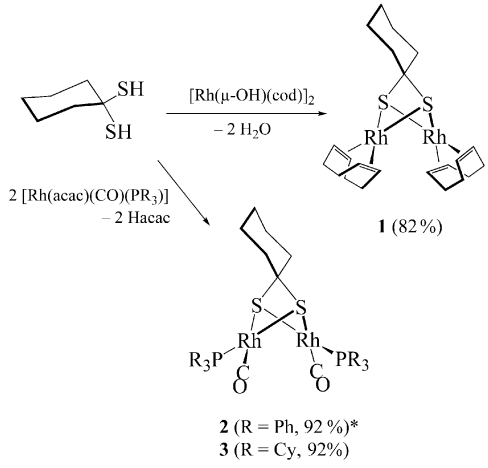

Figure 2. Synthesis of rhodium *gem*-dithiolato-bridged dinuclear complexes. (* cis isomer < 5%).

Compound **1** was used as a catalyst precursor, in the presence of monodentate P-donor ligands, for the hydroformylation of oct-1-ene under mild conditions of temperature and pressure (353 K and 100 PSI) (Figure 3). It has been found that the catalytic activity is strongly dependent on the P/Rh ratio. In the absence of P-donor ligands, no catalytic activity was observed at 100 PSI, although extensive isomerization to internal alkenes was observed at 200 PSI. Almost certainly, compound **1** is transformed into the inactive tetracarbonyl complex $[Rh_2(\mu\text{-}S_2Chxn)(CO)_4]$ under hydroformylation conditions, and an excess of $PR_3$ ligands is necessary to maintain a sufficient concentration of the possibly active phosphane-containing species $[Rh_2(\mu\text{-}S_2Chxn)(CO)_{4-x}(PR_3)_x]$. The optimum P/Rh ratio was found to be approximately 4, as higher ratios produce a slight decrease in the catalytic activity. The results obtained in the hydro-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

formylation of oct-1-ene under these optimized conditions are shown in Table 1. When $P(OMe)_3$ was used as the modifying ligand, conversions of 67.9% or 88.4% were obtained in 2 or 3 h (entries 1 and 2), respectively. In both catalytic runs, the aldehyde selectivity was as high as 97%, with regioselectivities of up to 81% for the linear aldehyde (only 1-nonanal and 2-methyl-octanal were obtained in the reactions). The by-products of these reactions were octane, the hydrogenation product, detected in trace amounts (<1%), and internal n-octenes, resulting from olefin isomerization (≈ 2%).

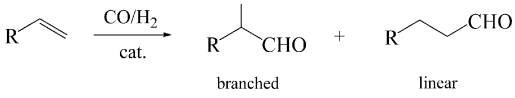

Figure 3. Hydroformylation of oct-1-ene (R = $-C_6H_{13}$).

Table 1. Hydroformylation of oct-1-ene with the complex $[Rh_2(\mu\text{-}S_2Chxn)(cod)_2]$ (**1**) as catalyst precursor.[a]

| Run | Ligand | P/Rh | *t* [h] | % Conv.[b] | % Aldehyde[b] | % *n*[b] | TOF [$h^{-1}$][c] |
|---|---|---|---|---|---|---|---|
| 1 | $P(OMe)_3$ | 4 | 2 | 67.9 | 97.2 | 81 | 198 |
| 2 | $P(OMe)_3$ | 4 | 3 | 88.4 | 97.4 | 80 | 172 |
| 3 | $P(OPh)_3$ | 4 | 2 | 96.5 | 76.7 | 83 | 222 |
| 4 | $PPh_3$ | 4 | 12 | 65.2 | 93.2 | 76 | 30 |
| 5 | $PCy_3$ | 4 | 12 | 43.9 | 93.0 | 54 | 20 |
| 6[d] | $PPh_3$ | 4 | 12 | 68.7 | 92.3 | 74 | 32 |

[a] Reaction conditions: 100 PSI ($CO/H_2$, 1/1), 353 K, oct-1-ene (10.2 mmol, 0.6 M), $[Rh_2(\mu\text{-}S_2Chxn)(cod)_2]$ (0.017 mmol, 1 mM). [b] Conversion, selectivity for aldehyde, and regioselectivity for the linear aldehyde (*n*) determined by GC. [c] TOF = $mol_{aldehyde}/[mol_{catalyst}]\cdot h^{-1}$ corresponds to the reaction time. [d] $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PPh_3)_2]$ (**2**) as catalyst precursor.

The catalytic system resulting from $P(OPh)_3$ (entry 3) is more active, reaching a 96.5% conversion in 2 h, with a similar regioselectivity. In contrast, this system is much less selective (aldehyde selectivity 76.7%) as a consequence of the high isomerization activity that produces internal n-octenes. However, neither 2-ethylheptanal nor 2-propylhexanal were detected by GC, which indicates that under these experimental conditions, the internal olefins were not hydroformylated.

The catalytic performance with phosphite ligands is superior than that observed with phosphane ligands, as they provided higher conversions for the same reaction times. The TOF for aldehyde production in these phosphite catalytic systems was found to be about 200 turnover/h. However, the catalytic systems obtained with triphenyl- or tricyclohexylphosphane as auxiliary ligands provided TOF numbers for the aldehyde of about 30 turnover/h (see Table 1). For example, when $PPh_3$ was used as the modifying ligand, a 65.2% conversion was attained in 12 h with good aldehyde selectivity (93.2%) and 76% regioselectivitiy for the linear aldehyde (entry 4). Although the same chemoselectivity was observed in the $PCy_3$ catalytic system, both the activity and the regioselectivity (54%) are considerably smaller (entry 5).

The investigation of the catalytic solutions after the catalytic runs when using $PPh_3$ as the P-donor ligand allowed the isolation of the dinuclear complex $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PPh_3)_2]$ (**2**). Compound **2** can also be prepared in a straightforward manner with an excellent yield from the reaction of $[Rh(acac)(CO)(PPh_3)]$ and $Chxn(SH)_2$ in a 2:1 molar ratio (Figure 2). The molecular structure of compound **2** was determined by X-ray diffraction and is shown in Figure 4. Selected bond lengths and angles are collected in Table 2. The dinuclear skeleton of **2** is held up by a 1,1-cyclohexanedithiolato ligand exhibiting a bridging and chelating coordination mode (1:2$\kappa^2$S, 1:2$\kappa^2$S′) that results in the formation of two fused four-membered metallacycles. The 1,1-cyclohexylene fragment adopts the usual chair conformation, and both rhodium atoms exhibit a distorted square-planar geometry by coordination to two additional CO and $PPh_3$ ligands. In contrast with dinuclear thiolato $[Rh(\mu\text{-}SR)(CO)(PR_3)]_2$ complexes, where the $PR_3$ ligands are usually in a *cis* arrangement to accommodate the *anti* conformation of the thiolate ligands,[14–16] the $PPh_3$ ligands in **2** adopt a mutually *trans* disposition.

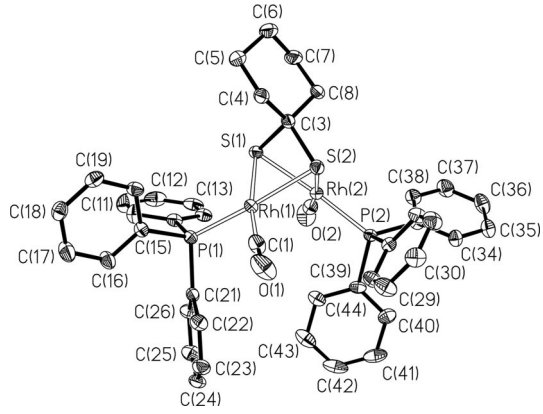

Figure 4. Molecular structure of the dinuclear complex $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PPh_3)_2]$ (**2**).

Table 2. Selected bond lengths [Å] and angles [°] for dinuclear compound $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PPh_3)_2]$ (**2**).

It is worth noting that the average Rh–S–Rh and S–Rh–S bond angles, 74.25(2)° and 71.07(2)°, are significantly smaller than those found in the related dinuclear dithiolate complexes *cis*-[Rh(μ-SPh)(CO)($PMe_3$)]$_2$ [79.3(5) and 81.0(1)°][15] and *cis*-[Rh(μ-S*t*Bu)(CO)($PPh_3$)]$_2$ [81.6(3) and 80.7(3)°].[16] Both parameters are strongly influenced by the narrow angle of 96.82(12)° centered on the bridgehead carbon atom of the 1,1-cyclohexanedithiolato ligand [S(1)–C(3)–S(2)] that enables the S donor atoms to come closer together [nonbonding S···S distance of 2.7833(10) Å] and, in turn, this results in a very small angle of 91.04(2)° between both rhodium coordination planes (defined only by the metal-coordinated atoms) and a short Rh···Rh distance of 2.8903(3) Å [112.25(3) and 111.61(12)°, 3.061(1) and 3.103(6) Å in the above-mentioned dithiolate complexes, respectively]. The $RhS_2Rh$ torsion angle of 95.76(2)°, which is closely related to the Rh···Rh distance, is slightly larger than the angle between the coordination planes, as a consequence of the separation of the metal atoms from their coordination planes by 0.0635(2) and 0.1670(2) Å [Rh(1) and Rh(2), respectively]. This fact reflects the existence of a feeble repulsion between the metal atoms that is due to the ligand-forced, short metal–metal nonbonding distance, as suggested before in other similar cases.[9,17]

The geometrical constraints imposed by the *gem*-dithiolato ligand in **2** relative to the other dithiolato ligands are largely reflected both in the smaller S–Rh–S angles, 79.02(6) and 84.49(19)° in the complexes [Rh(μ-S$(CH_2)_2$S)(cod)$_2$] and [Rh(μ-S$(CH_2)_3$S)(cod)$_2$],[9] and in the smaller angle between the rhodium coordination planes, 96.95 and 103.99 respectively, although the Rh–S–Rh angles and the Rh···Rh distances are of comparable magnitude. On the other hand, the structural parameters of the central core in **2** compares well with those observed in the structurally related dinuclear compound [$Rh_2${μ-$S_2$CN(Me)(Ph)}(cod)$_2$], which has a dithiocarbamate bridging ligand exhibiting the same coordination mode.[18]

The spectroscopic data indicate that compound **2** exists in solution mainly as the *trans* isomer, which was observed as a complex resonance in the $^{31}P\{^1H\}$ NMR ($C_6D_6$) spectrum at $\delta$ = 41.90 ppm. This signal correlates well with the calculated spectrum using the parameters reported in the Experimental Section, which resulted from the consideration of small $^2J_{Rh-P}$, $^3J_{P-P}$, and $J_{Rh-Rh}$ coupling constants.[19] However, the *cis* isomer was also observed (<5%) as a doublet at $\delta$ = 39.6 ($J_{Rh-P}$ = 162 Hz). The dinuclear compound [$Rh_2$(μ-$S_2$Chxn)(CO)$_2$($PCy_3$)$_2$] (**3**) was prepared in excellent yield following a similar synthetic protocol starting from [Rh(acac)(CO)($PCy_3$)] (Figure 2). The $^{31}P\{^1H\}$ NMR ($C_6D_6$) spectrum only shows a resonance at $\delta$ = 53.10 ppm with a similar pattern to that found in the spectrum of compound **2** and suggests that compound **3** exists exclusively as the *trans* isomer. This fact is probably associated to the bulkiness of the $PCy_3$ ligands that completely disfavors the formation of the *cis* isomer. The signals for the equivalent carbonyl groups are observed in the $^{13}C\{^1H\}$ NMR ($C_6D_6$) spectra of both compounds as a doublet of doublets at $\delta$ = 192.2 (**2**) and 191.8 ppm (**3**) ($J_{Rh-C}$ = 75 Hz, $^2J_{P-C}$ = 17 Hz). The IR spectra of both compounds in dichloromethane show a broad $\nu$(CO) band for the terminal carbonyl groups at 1957 (**2**) and 1960 $cm^{-1}$ (**3**), which is in good agreement with a *trans* disposition of the ligands.[7b,7f,10b]

The mixed-carbonyl compound **2** is also an active precursor in the hydroformylation of oct-1-ene. Although related dinuclear thiolate systems have shown that diolefin complexes, in the presence of $PR_3$ ligands, are more active than the mixed carbonyl-phosphane species under the same experimental conditions,[7f] in the present case comparable chemoselectivity, regioselectivity, and activity are obtained when using the same P/Rh ratio (entry 6).

The results presented in Table 1 indicate that the activity of the catalytic systems decrease with the basicity of the P-donor ligands. Interestingly, the reverse trend was shown for dinuclear systems based on functionalized amino-thiolate ligands in the hydroformylation of hex-1-ene.[7e,7f] On the other hand, it is evident that the regioselectivity is not controlled exclusively by steric factors since the more sterically demanding ligand ($PPh_3$) affords the lower regioselectivities. This fact was already observed in the hydroformylation of hex-1-ene with a cationic dinuclear catalyst precursor having an aminothiolato-bridged ligand.[7f]

As far as the nuclearity of the active species during catalysis is concerned, we are aware that, under hydroformylation conditions, some dinuclear rhodium complexes containing thiolate bridging ligands are precursors of the mononuclear rhodium(I) hydrido species that probably account for the catalytic activity.[12] In spite of the obtained regioselectivities, that are roughly comparable to those observed in the catalytic systems [Rh(acac)$(CO)_2$]/$PPh_3$ and [Rh(acac)$(CO)_2$]/P$(OPh)_3$, the recovery of the dinuclear compound **2** after the catalytic reaction in the system **1**/$PPh_3$ and the singular structural features of the compact [Rh(μ-$S_2CR_2$)Rh] core strongly motivate us to look further into the chemical behavior of these types of compounds. Further studies on the synthesis and reactivity of dinuclear rhodium complexes containing new *gem*-dithiolato ligands are currently under way, in order to determinate the influence of the bridging ligand on the catalytic activity and to analyze a potential intermetallic cooperative mechanism in these dimetallic species.

## Conclusions

We have shown that novel dinuclear *gem*-dithiolato-bridged rhodium complexes can easily be obtained in high yields directly by double deprotonation of a *gem*-dithiol compound by using mono- or dinuclear rhodium complexes containing basic ligands. The diolefin compound [$Rh_2$(μ-$S_2$Chxn)(cod)$_2$] (**1**) is an active catalyst precursor in the presence of P-donor ligands for the hydroformylation of oct-1-ene under mild conditions. The performance of the resulting catalytic systems is strongly dependent on the nature of the modifying P-donor ligand, and it has been found that ligands of the type P$(OR)_3$ are better than $PR_3$ ligands in terms of both activity and selectivity.

## Experimental Section

**General:** All manipulations were performed under a dry argon atmosphere by using Schlenk-tube techniques. Solvents were dried by standard methods and distilled under argon immediately prior to use. Standard literature procedures were used to prepare the complexes $[Rh(\mu\text{-}OH)(cod)]_2$,[20] $[Rh(acac)(CO)(PPh_3)]$,[21] and $[Rh(acac)(CO)(PCy_3)]$.[22] 1,1-Dimercaptocyclohexane was prepared according to the reported method.[23] Oct-1-ene was purchased from Aldrich and was distilled prior to use.

**Physical Measurements:** $^1H$, $^{31}P\{^1H\}$, and $^{13}C\{^1H\}$ NMR spectra were recorded on a Varian Gemini 300 spectrometer operating at 300.08 MHz for $^1H$. Chemical shifts are reported in parts per million and referenced to $SiMe_4$ by using the residual resonances of the deuterated solvents ($^1H$ and $^{13}C$) and 85% $H_3PO_4$ ($^{31}P$) as external reference. Assignments in complex NMR spectra were made by simulation with the program gNMR© v 3.6 (Cherwell Scientific Publishing Limited) for Macintosh. The initial choice of chemical shifts and coupling constants were optimized by successive iterations following a standard least-squares procedure; a numerical assignment of the experimental frequencies was used. IR spectra were recorded on a Nicolet-IR 550 spectrometer. Elemental C, H and N analysis were performed with a Perkin–Elmer 2400 microanalyzer. Molecular weights were determined with a Knauer osmometer by using chloroform solutions of the complexes. Mass spectra were recorded in a VG Autospec double-focusing mass spectrometer operating in the $FAB^+$ mode. Ions were produced with the standard $Cs^+$ gun at ca. 30 Kv; 3-nitrobenzylic alcohol (NBA) was used as matrix. Hydroformylation experiments were carried out in a stainless steel magnetically stirred autoclave (100 mL) equipped with a thermocouple and an external heating mantle. The syngas ($CO/H_2$ = 1) was supplied at constant pressure from a ballast. The drop in pressure in the ballast was monitored by using a pressure transducter.

**Preparation of $[Rh_2(\mu\text{-}S_2Chxn)(cod)_2]$ (1):** To a solution of $[Rh(\mu\text{-}OH)(cod)]_2$ (0.502 g, 1.100 mmol) in $CH_2Cl_2$ (5 mL) was added 1,1-dimercaptocyclohexane ($Chxn(SH)_2$, 170 μL, 1.241 mmol, $\rho$ = 1.083 g mL$^{-1}$) to give a red-orange solution, which was stirred for 15 min. The addition of EtOH (10 mL) gave a red suspension, which was concentrated under vacuum to ca. 5 mL and then filtered to give a red-orange microcrystalline solid, which was washed with EtOH (2 × 3 mL) and dried under vacuum. Yield: 0.511 g (82%). $C_{22}H_{34}Rh_2S_2$ (568.44): calcd. C 46.48, H 6.03, S 11.28; found C 46.53, H 6.05, S 11.53. $^1H$ NMR (300.08 MHz, $CDCl_3$, 293 K): $\delta$ = 4.54 (m, 4 H, =CH), 4.23 (m, 4 H, =CH, cod), 2.43 (m, 12 H, $>CH_2$, cod and Chxn), 1.98 (m, 4 H, $>CH_2$), 1.83 (m, 4 H, $>CH_2$, cod), 1.44 (m, 4 H, $>CH_2$), 1.26 (m, 2 H, $>CH_2$, Chxn) ppm. $^{13}C\{^1H\}$ NMR (75.46 MHz, $CDCl_3$, 293 K): $\delta$ = 84.0 (C1, Chxn), 79.8 (d, $J_{Rh-C}$ = 12 Hz, =CH), 79.1 (d, $J_{Rh-C}$ = 12 Hz, =CH, cod), 57.2 (C2 and C6, Chxn), 31.4 and 31.1 ($>CH_2$, cod), 24.3 (C4), 22.0 (C3 and C5, Chxn) ppm. MS ($FAB^+$, $CH_2Cl_2$): *m/z* (%) = 568 (100) [$M^+$] 460 (60) [$M^+$ – cod]. Mol. weight ($CHCl_3$): calcd 568; found 562.

**Preparation of $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PPh_3)_2]$ (2):** To a suspension of $[Rh(acac)(CO)(PPh_3)]$ (0.501 g, 1.018 mmol) in diethyl ether (15 mL) was added $Chxn(SH)_2$ (73 μL, 0.533 mmol, $\rho$ = 1.083 g mL$^{-1}$) to immediately give an orange solution, which was stirred for 15 min. The addition of MeOH (15 mL) gave an orange suspension, which was stirred for 5 min and concentrated under vacuum to about one half of the original volume and then filtered to give an orange solid, which was washed with cold MeOH (2 × 5 mL) and dried under vacuum. Yield: 0.433 g (92%). $C_{44}H_{40}O_2P_2Rh_2S_2$ (932.68): calcd. C 56.66, H 4.32, S 6.87; found C 56.68, H 5.15, S 6.85. $^1H$ NMR (300.08 MHz, $C_6D_6$, 293 K): $\delta$ = 7.93 (m, 12 H), 7.05 (m, 18 H, $PPh_3$), 2.63 (m, 4 H, $>CH_2$), 1.45 (m, 4 H, $>CH_2$), 1.07 (m, 2 H, $>CH_2$, Chxn) ppm. $^{13}C\{^1H\}$ NMR (75.46 MHz, $C_6D_6$, 293 K): $\delta$ = 192.2 (dd, $J_{Rh-C}$ = 75, $^2J_{P-C}$ = 17 Hz, CO), 135.5 (d, $J_{P-C}$ = 45 Hz), 134.4 (d, $J_{P-C}$ = 12 Hz), 130.1, 128.5 (d, $J_{P-C}$ = 12 Hz, $PPh_3$), 86.7 (C1), 57.6 (C2 and C6), 24.6 (C4), 21.7 (C3 and C5, Chxn) ppm. $^{31}P\{^1H\}$ NMR (121.47 MHz, $C_6D_6$, 293 K): $\delta$ = 41.90 (AA′XX′ spin system, A = $^{31}P$ and X = $^{103}Rh$, calcd. spectrum: $J_{Rh-P}$ = 163.72 Hz, $^2J_{Rh-P}$ = –1.47 Hz, $^3J_{P-P}$ = 6.60 Hz, $J_{Rh-Rh}$ = 3.59 Hz, *trans* isomer), 39.6 (d, $J_{Rh-P}$ = 162 Hz, *cis* isomer). MS ($FAB^+$, $CH_2Cl_2$): *m/z* (%) = 932 (25) [$M^+$] 904 (20) [$M^+$ – CO], 876 (15) [$M^+$ – 2CO], 532 (100) [$M^+$ – Chxn – 2CO – $PPh_3$]. Mol. Weight ($CHCl_3$): calcd 932; found 940. IR (pentane ): $\nu$(CO) = 1957 (s) cm$^{-1}$.

**Preparation of $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PCy_3)_2]$ (3):** $[Rh(acac)(CO)(PCy_3)]$ (0.367 g, 0.719 mmol) and $Chxn(SH)_2$ (50 μL, 0.365 mmol, $\rho$ = 1.083 g mL$^{-1}$) were reacted in diethyl ether (15 mL) for 15 min to give an orange suspension. The suspension was concentrated under vacuum to about one half the volume and cooled to –85 °C. The orange microcrystalline solid was filtered, washed with cold pentane (2 × 5 mL), and dried under vacuum. Yield: 0.319 g (92%). $C_{44}H_{76}O_2P_2Rh_2S_2$ (968.96): calcd. C 54.54, H 7.90, S 6.62; found C 54.22, H 7.98, S 6.50. $^1H$ NMR (300.08 MHz, $CDCl_3$, 293 K): $\delta$ = 2.85 (m, 6 H, $PCy_3$), 2.19–2.06 (m, 28 H), 1.80–1.65 (m, 28 H), 1.25–1.10 (m, 14 H), ($PCy_3$, Chxn) ppm. $^{13}C\{^1H\}$ NMR (75.46 MHz, $CDCl_3$, 293 K): $\delta$ = 191.8 (dd, $J_{Rh-C}$ = 75, $^2J_{P-C}$ = 17 Hz, CO), 84.5 (C1), 57.1 (C2 and C6, Chxn), 35.7 (d, $J_{P-C}$ = 21Hz), 26.8 (d, $J_{P-C}$ = 11 Hz), 26.7 (d, $J_{P-C}$ = 10 Hz), 25.7 ($PCy_3$), 23.9 (C4), 21.1 (C3 and C5, Chxn) ppm. $^{31}P\{^1H\}$ NMR (121.47 MHz, $C_6D_6$, 293 K): $\delta$ = 53.10 (AA′XX′ spin system, A = $^{31}P$ and X = $^{103}Rh$, calcd. spectrum: $J_{Rh-P}$ = 158.30 Hz, $^2J_{Rh-P}$ = –0.54 Hz, $^3J_{P-P}$ = 3.79 Hz, $J_{Rh-Rh}$ = 3.74 Hz, *trans* isomer). MS ($FAB^+$, $CH_2Cl_2$): *m/z* (%) = 968 (100) [$M^+$], 938 (96) [$M^+$ – CO – 2 H], 908 (65) [$M^+$ – 2CO – 4 H]. Mol. weight ($CHCl_3$): calcd 968; found 970. IR (pentane ): = $\nu$(CO) = 1960 (s) cm$^{-1}$.

**Standard Hydroformylation Experiment:** In a typical run, a solution of the catalyst precursor $[Rh_2(\mu\text{-}S_2Chxn)(cod)_2]$ (**1**) (0.017 mmol), which contains the phosphane or phosphite ligand (0.20–0.60 mmol), oct-1-ene (10.2 mmol), and toluene (15.4 mL), was transferred from a Schlenk tube under argon to the autoclave by using a stainless steel cannula. The autoclave was purged with syngas three times at 120 PSI and then pressurized at 50 PSI and heated at 80 °C. When thermal equilibrium was reached, the pressure was adjusted to 100 PSI, and the mixture stirred for 8 h with the continuous supply of syngas at constant pressure. After the reaction time, the autoclave was cooled to room temperature and depressurized. The reaction mixture was analyzed by gas chromatography with a Hewlett–Packard 5890 instrument equipped with a capillary column (HP, ULTRA 1. 25 m × 0.32 mm × 0.17 μm) and a flame-ionization detector. The products were quantified by the internal standard method by using anisole.

**Crystal Structure Determination of $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PPh_3)_2]$ (2):** Suitable crystals for X-ray diffraction of compound **2** were obtained from a saturated solution of the complex in dichloromethane/(diethyl ether) at 258 K. A summary of the crystal data, data collection, and refinement parameters are given in Table 3. Intensity data were collected at low temperature [150(2) K] on a Bruker SMART diffractometer (equipped with a CCD area detector) by using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). Data were integrated with the Bruker SAINT package,[24] and absorption corrections were applied by the SADABS program.[25] The

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

structure was solved by direct methods and completed by subsequent difference Fourier techniques. Refinement on $F^2$ was carried out by full-matrix least-squares methods (SHELXL97).[26] All non-hydrogen atoms were refined with anisotropic displacement parameters; all hydrogen atoms were observed in the difference Fourier maps and refined as free isotropic atoms. CCDC-654127 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Table 3. Crystal data, data collection, and refinement parameters for the X-ray analysis of $[Rh_2(\mu\text{-}S_2Chxn)(CO)_2(PPh_3)_2]$ (**2**).

# *ortho*-Directed Metathetical Fluoride/Amide Exchange in (Pentafluorophenyl)-amides[‡]

**Pavel L. Shutov,[a] Sergey S. Karlov,*[b] Klaus Harms,[a] Maxim V. Zabalov,[b] Jörg Sundermeyer,*[a] Jörg Lorberth,[a] and Galina S. Zaitseva[b]**

**Keywords:** Fluorinated ligands / Amides / Nucleophilic substitution / Density functional calculations

The indium tris(amide)s $[(Et_2N)_{3-n}In\{N(C_6F_5)(2\text{-}C_5H_4N)\}_n]$ [*n* = 1 (**15**), 2 (**16**) or 3 (**9**)] have been prepared by treatment of $[In(NEt_2)_3]_2$ (**3**) with a stoichiometric amount of $(2\text{-}C_5H_4N)(C_6F_5)NH$ (**1**). The analogous reaction of $Bi(NMe_2)_3$ (**2**) with 3 equiv. of amine **1** and the treatment of $BiCl_3$ (**5**) with a stoichiometric amount of $(2\text{-}C_5H_4N)(C_6F_5)NLi$ (**4**) both lead to $[Bi\{N(C_6F_5)(2\text{-}C_5H_4N)\}_3]$ (**10**). In contrast, only the difluoride **11** or the monofluoride **12**, which are the products of intramolecular *ortho*-directed exchange of $NMe_2$ and F substituents, are obtained from the reaction of **2** with 1 or 2 equiv. of **1**, respectively. The reaction between $Me_3Sb(Hal)_2$ [Hal = Br (**7**) Cl, (**8**)] and 1 or 2 equiv. of lithium salt **4** gives the corresponding stable monoamides $[Me_3(Hal)Sb\{N(C_6F_5)(2\text{-}C_5H_4N)\}]$ [Hal = Br (**17**), Cl (**18**)] or bis(amide) $[Me_3Sb\{N(C_6F_5)(2\text{-}C_5H_4N)\}_2]$ (**19**), respectively. The structure of **9** has been confirmed by an X-ray structure analysis, and density functional calculations data have been used to explain the possible reaction pathway of the *ortho*-directed metathetical fluoride/amide exchange.

## Introduction

There has been a strong interest in activation of the C–F bond in polyfluoro organic compounds during the past several decades due to the possible utilization of these activation processes in organic synthesis.[2,3] A variety of methods for activating C–F bonds with transition metal centers have been published recently, and several examples based on early, middle, or late transition metal compounds have been used for the replacement of an F atom in polyfluoroaryl moieties, mostly by oxidative addition reactions.[4–11] Nucleophilic substitution reactions of an aryl carbon–fluorine bond assisted by main group element compounds (alkali and alkaline earth metals or silicon derivatives) have also been widely investigated.[4,5,12,13] However, to the best of our knowledge, most of the mechanistically studied examples have been ascribed to *intermolecular* processes. Assumptions about *intramolecular* pathways have been made exclusively for *ortho*-directed fluorine atom substitution for $C_6F_5X$ species (X is a *ortho*-directing donor functionality) in reactions with Li or Mg reagents such as ArLi, RMg(Hal), ArMg(Hal) or ArN(R)Mg(Hal).[13,14]

Recently, we reported the reaction of $Sb(NEt_2)_3$ with $C_6F_5(2\text{-}C_5H_4N)NH$ (**1**), which leads to the antimony tris(amide)s $[(Et_2N)_2Sb\{N(C_6F_5)(2\text{-}C_5H_4N)\}]$, $[(Et_2N)Sb\{N(C_6F_5)(2\text{-}C_5H_4N)\}_2]$, and $[Sb\{N(C_6F_5)(2\text{-}C_5H_4N)\}_3]$ with one, two, or three pentafluoro(2-pyridyl)anilido groups.[1] Trivalent antimony compounds containing one or two $NEt_2$ groups are unexpectedly unstable, and they rearrange to give the bis(amido)antimony fluorides $[SbF\{N(C_6F_5)(2\text{-}C_5H_4N)\}_2]$ and $[(Et_2N)SbF\{N(C_6F_5)(2\text{-}C_5H_4N)\}]$, in almost quantitative yield at room temperature within 21 d.[1] To the best of our knowledge no such intramolecular rearrangements have been reported previously except in a paper by Schrock et al., where a similar nucleophilic substitution product is reported in low yield in the reaction of $Mo(NMe_2)_4$ with $(C_6F_5NHCH_2CH_2)_2NMe$.[15] In order to gain further insight into the fluoride/amide metathesis assisted by antimony, and to expand the scope of this reaction, we report herein our investigation of the analogous transamination reactions of $Bi(NMe_2)_3$ (**2**) and $[In(NEt_2)_3]_2$ (**3**) with $C_6F_5NH(2\text{-}C_5H_4N)$ (**1**). The reactions of the lithium salt of amine **1**, namely $C_6F_5NLi(2\text{-}C_5H_4N)$ (**4**), with $BiCl_3$ (**5**), $InCl_3$ (**6**), $Me_3SbBr_2$ (**7**), and $Me_3SbCl_2$ (**8**) are also reported. The structure of the novel monomeric indium tris(amide) $[In\{N(C_6F_5)(2\text{-}C_5H_4N)\}_3]$ (**9**) is confirmed by X-ray crystallography, and density functional calculations are used to distinguish possible rearrangement pathways.

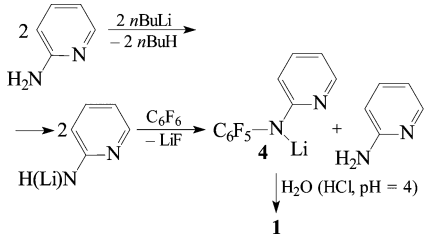
## Results and Discussion

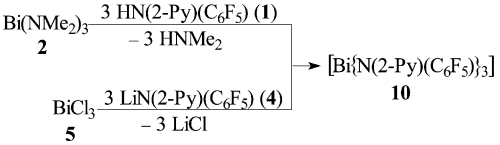
### Synthesis

Ligand **1** was first prepared by treating 2-bromopyridine with (pentafluorophenyl)amine,[16] although recently Ashenhurst et al. have used the approach of Koppang for the synthesis of **1**,[17] which involves the treatment of $C_6F_6$ with an equimolar mixture of (2-pyridylamido)lithium and $LiNH_2$.[18] We also used this reaction to prepare amine **1**, although we modified the method according to Equation (1). The twofold excess of lithiated 2-pyridylamine per mol of $C_6F_6$ is essential as product **1** is acidic enough to quench the nucleophile.



(1)

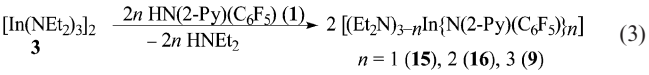
Treatment of $Bi(NMe_2)_3$ (**2**) with 3 equiv. of amine **1** in toluene and the reaction of lithium amide **4** with $BiCl_3$ (**5**) both afforded tris(amide) **2** in good yield [Equation (2)].



(2)

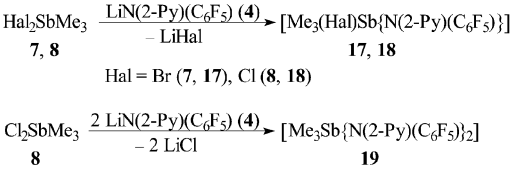
Treatment of $Bi(NMe_2)_3$ (**2**) with 1 or 2 equiv. of amine **1** led to difluoride **11** and monofluoride **12**, respectively, as products of a rearrangement reaction (Scheme 1). The instability of the plausible intermediates $[(NMe_2)_{3-n}Bi\{N(C_6F_5)(2\text{-}C_5H_4N)\}_n]$ is in sharp contrast to the corresponding antimony compounds, which only rearrange after extended reaction times.[1] Moreover, traces of both **11** and **12** were detected by NMR spectroscopy during the reaction of **2** with 3 equiv. of **1**. Thus, intramolecular nucleophilic substitution at a $C_6F_5$ moiety assisted by bismuth proceeds much faster than that for antimony derivatives. Hydrolysis of **11** and **12** led to the tris(amine)s **13** and **14**, which are difficult to synthesize by other methods.

In contrast to the reaction patterns of Sb and Bi compounds, the transamination of In amide **3** with 1, 2, and 3 equiv. of **1** selectively led to the corresponding tris(amide)s **15**, **16**, and **9**, respectively. No similar rearrangement processes were found in these studies [Equation (3)].



(3)

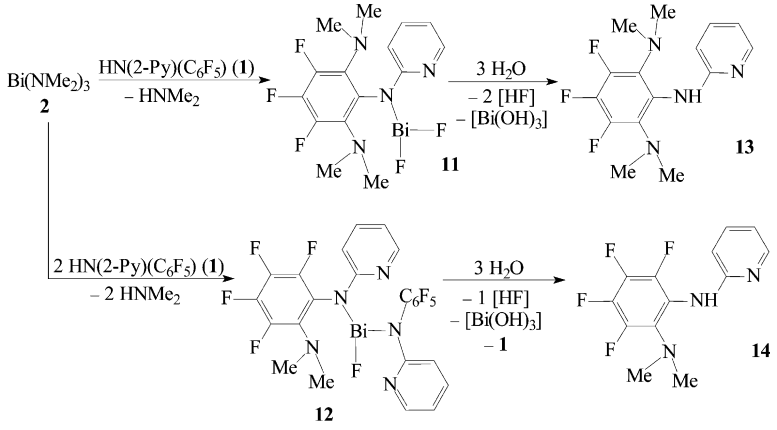
The tendency to rearrange is higher for compounds with a large covalent radius, low coordination number, and highly polar M–N bonds. We assume that this is probably more due to kinetic than to thermodynamic reasons. If the covalent character in M–N bonding is increased, for example by increasing the formal oxidation state of the central atom, the compounds become more inert with respect to rearrangement reactions: we observed that reaction of 1 or 2 equiv. of lithium amide **4** with $(Hal)_2SbMe_3$ (**7** and **8**) led to the expected unrearranged monoamides **17** and **18** or diamide **19** [Equation (4)]. While $Sb^{III}$ amides tend to rearrange, $Sb^{V}$ amides are inert with respect to this fluoride/amide exchange under ambient conditions.



(4)

### NMR Spectroscopic Study

The $^1H$, $^{13}C$, and $^{19}F$ NMR spectra of all compounds are consistent with a $\kappa^2$-*N*,*N*′-bonding mode of the 2-pyridylamido ligands. The solution spectra of bismuth fluo-



Scheme 1.

rides **11** and **12** are very similar to their previously characterized Sb analogs.[1] As already observed, the presence of one or two $NMe_2$ groups adjacent to the *ipso*-C atom of the aromatic rings inhibits the rotation of these moieties about the N–$C_{ipso}$ bond. N-coordination in a chelate ring leads to the appearance of two signals for the $NMe_2$ group in the $^1H$ NMR spectra of **11** and **12**. In accordance with these data, we assume that indium compounds **9**, **15**, and **16** are monomeric chelate complexes in $C_6D_6$ solutions.

It should be noted that two different configurations (*fac* and *mer*) are possible for indium and bismuth tris(amide)s **9** and **10**. Ashenhurst et al. found recently that the closely related Al derivative $[Al\{N(C_6F_5)(2\text{-}C_5H_4N)\}_3]$ undergoes a dynamic *fac*/*mer* isomerization in $CDCl_3$ solutions at 25 °C.[18] The broadening of the signals in the $^1H$ and $^{13}C$ NMR spectra of **9** and **10** indicates that a similar isomerization process probably takes place here as well. The ability of both **9** and **10** to isomerize in solution was confirmed by the very close values of total energy for both isomers (see Density Functional Calculations section below).

### Molecular Structure of 9

The molecular structure of **9** is shown in Figures 1 and 2, and Table 1 summarizes selected geometrical parameters. Compound **9** possesses a monomeric structure in the solid state. The coordination sphere of the indium atom is a distorted $InN_6$ octahedron with three amido groups and three pyridyl nitrogen atoms in a *fac* arrangement similar to the structurally related complex $[Al\{N(C_6F_5)(2\text{-}C_5H_4N)\}_3]$.[18] The distortion from octahedral geometry appears to be induced by the steric constraints of the $C_6F_5N(2\text{-}C_5H_4N)$ ligand. Analysis of the Cambridge Structural Database (Version 5.28, November 2006)[19] reveals more than ten structures with a similar $InN_6$ structural fragment, most of which contain either pyrazolylborate or phthalocyanine ligands or have ionic structures such as $In(NCS)_6^{3-}$. Interestingly, the most closely related structure, that of $[In(N_3)_3\text{-}Py_3]$,[20] possesses a *mer* configuration. As expected, the covalent In–$N_{amido}$ bonds in **9** [2.174(3)–2.202(2) Å] are shorter than the donor–acceptor In–$N_{Py}$ bonds [2.259(2)–2.324(3) Å].

No short contacts between In and the fluorine atoms of the $C_6F_5$ groups are found in the solid state. The shortest In···F contact in **9** of 3.585 Å (where F is an *ortho*-fluorine

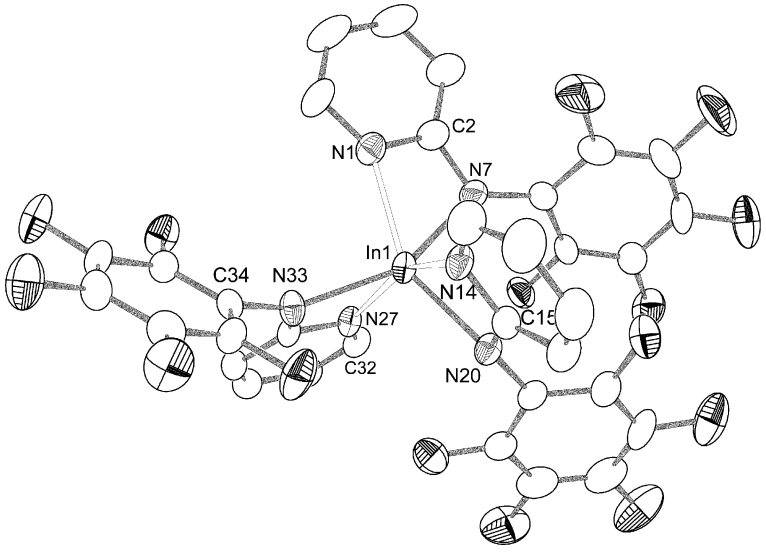

Figure 1. Thermal ellipsoid drawing of complex **9**. Hydrogen atoms and disordered toluene have been omitted for clarity. Displacement ellipsoids are drawn at the 50% probability level.

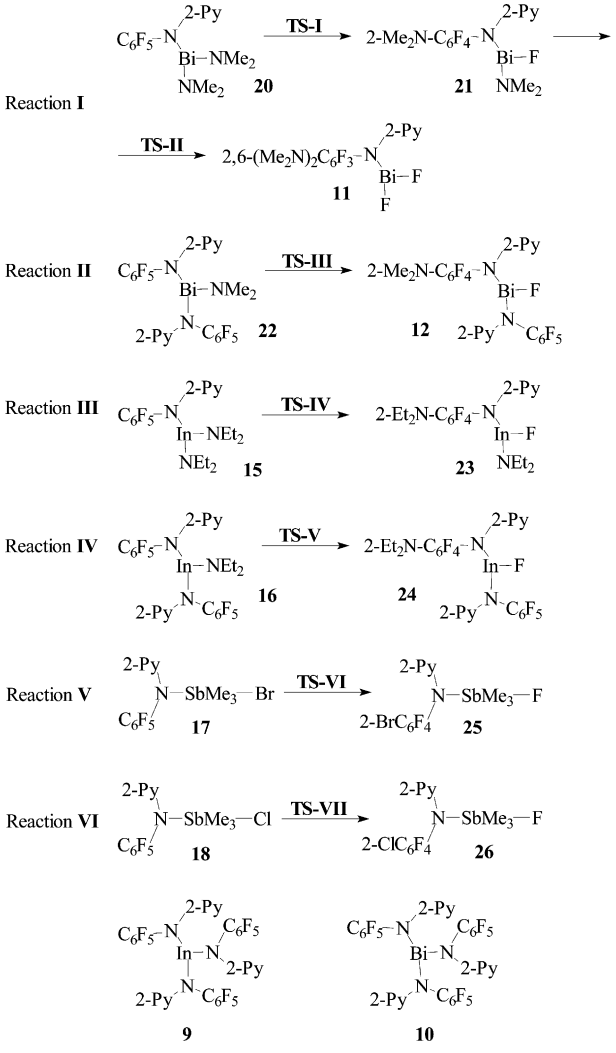
 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

atom) is larger than the sum of the van der Waals radii of indium and fluorine (3.40 Å).[21]

### Density Functional Study on Metal Complexes and Nucleophilic Substitution Reactions

To gain a better understanding of the driving force behind the *ortho*-directed metathetic fluoride/amide rearrangements we carried out density functional calculations at the PBE level of theory on a number of stable compounds and metastable intermediates on the reaction coordinate. The calculated structures and the reactions studied are presented in Scheme 2.



Scheme 2.

The compounds are likely to possess intramolecular contacts between the metal atom and the pyridine nitrogen atoms, therefore two different types of molecules were studied: derivatives containing additional intramolecular $N_{Py}\rightarrow M$ contacts (a) and derivatives without these contacts (b). In the cases where several additional $N_{Py}\rightarrow M$ contacts are possible, structures with the maximum number of contacts were calculated. The most important geometry parameters of species in series (a) are listed in Table 2; the calculated molecular structures of the compounds studied, the most important geometry parameters of these species, and the values of their total energies are listed in the Supporting Information. According to the results of the density functional calculations, the values of total energy for derivatives (a) with $N_{Py}\rightarrow M$ bonds are larger than those for the corresponding compounds (b) without these contacts for all species studied. The differences between the energy values for the starting materials lie within the range 7.03 (**20**) to 35.04 kcal mol$^{-1}$ (**16**). The analogous values for the rearrangement products are 5.89 (**20**) to 41.27 kcal mol$^{-1}$ (**16**).

It is of interest to note that the total energy of **9a**(*fac*) is practically identical to that of **9a**(*mer*): $\Delta E = E$[**9a**(*fac*)] – $E$[**9a**(*mer*)] = 1.16 kcal mol$^{-1}$; the same $\Delta E$ value was found for the Bi compound **10a**. This energy equivalence testifies to the possibility of *fac*/*mer* conformational exchange in solution for **9** and **10**, as proposed on the basis of the NMR spectroscopic data. The total energy values of **9a** and **10a**, which possess $N_{Py}\rightarrow M$ bonds, are also larger than those for **9b** and **10b**, respectively. These differences are 51.41 [**9**(*fac*)] and 52.49 kcal mol$^{-1}$ [**9**(*mer*)], and 39.56 [**10**(*fac*)] and 35.31 kcal mol$^{-1}$ [**10**(*mer*)]. We can therefore expect that all metal derivatives of the $C_6F_5N(2\text{-}C_5H_4N)$ ligand in question possess intramolecular coordination in solution [series (a)].

It should be noted that the calculated parameters of compound **9a**(*fac*) (In–$N_{amido}$ 2.256 Å; In–$N_{Py}$ 2.332–2.333 Å) are close to those found for the solid-state structure of **9** (see above). Consequently, we believe that the theoretical method used gives reasonable results for indium derivatives; the appropriateness of this method for Sb and Bi compounds was confirmed by us previously.[1,22]

Taking into consideration that no X-ray structure of prepared or proposed compounds is reported except for that of **9a**, the calculated geometrical data for the molecules studied [series (a), with $N_{Py}\rightarrow M$] are of particular interest. The primary coordination environment of the Bi atom in **11a**, **12a**, and **20a**–**22a** may be treated as a trigonal pyramid as the Bi–$N_{Py}$ distances are smaller than the sum of the van der Waals radii of bismuth and nitrogen (3.94 Å).[21] Consequently, the Bi atom can be regarded as [3+1]-coordinate in **20a** and [3+2]-coordinate in **22a**. Analogous [3+2]-coordination is found in **11a** due to additional interaction of the Bi atom with one $NMe_2$ group. In contrast to **11a**, however, the Bi atom in **21a** should be regarded as [3+1]-coordinate because no interaction between the Bi atom and $NMe_2$ group is found in this compound. The Bi atom in **12a** possesses three additional contacts with nitrogen atoms (two $N_{Py}$ and one $NMe_2$), which means that the distortion of the primary trigonal-pyramidal coordination environment of the bismuth atom is maximal. The starting compounds **20a**, **21a**, and **22a** also possess a short Bi–F contact (3.592, 3.378, and 3.431 Å, respectively).

The coordination polyhedron of the In atom in **15a** and **16a** is a distorted tetrahedron (two In–$NEt_2$ and one In–$N_{amide}$ and In–$N_{Py}$ bonds) and a distorted trigonal bipyramid (In–$NEt_2$ and two In–$N_{amide}$ and In–$N_{Py}$ bonds),

[a] Shortest distance for the molecule. [b] Splitting bond. [c] Nascent bond. [d] No interaction. [e] Covalent bond. [f] Dative bond.

respectively. Compounds **15a** and **16a** also possess a short In–F contact (3.524 and 3.420 Å, respectively). These values are comparable with those found for bismuth derivatives (see above), although the smaller covalent and van der Waals radii of indium in comparison with those of bismuth should be noted.

The coordination polyhedron of the Sb atom in **17a** and **18a** is a distorted octahedron (three Sb–$CH_3$ and one Sb–$N_{amide}$, Sb–Hal, and Sb–$N_{Py}$ bonds). These compounds do not possess any short Sb–F contacts (shortest distance: 3.721 and 3.729 Å, respectively).

As stated above, six reactions were studied during this work (Scheme 2). Analysis of the total energy values for the starting materials and products (Table 3) shows that the products are thermodynamically more favored in all the reactions studied. However, the experimental results show that reactions **I** and **II** proceed completely and compounds **20**–**22** are not detected in the reaction mixtures, while reactions **III**–**VI** do not take place. This means that kinetic factors are the key to understanding the origin of these processes. We therefore calculated the transition-state (TS) geometries of reactions **I**–**VI** for structures with (**TSIa**–**TSVIIa**) and without (**TSIb**–**TSVIIb**) $N_{Py}$→M interactions. The most important geometrical parameters of species in series (a) are listed in Table 2 and the molecular structures of the TSs studied, their atomic coordinates, and the total energy values are given as Supporting Information. Table 3 summarizes the relative energy values for the species studied, including the transition states **I**–**VII** (the activation barriers).

The computed barriers (Table 3) for the observed reactions **20a** → **21a**, **21a** → **11a**, and **22a** → **12a** in the gas phase are low (17.64–24.41 kcal mol$^{-1}$), while those for reactions **III**–**VI** are considerably higher (46.23–50.57 kcal mol$^{-1}$). The values found for the activation barrier in reactions **I** and **II** are very close to those previously found for the reaction [$(Et_2N)Sb\{N(C_6F_5)(2\text{-}C_5H_4N)\}_2$] → [$SbF\{N(C_6F_5)(2\text{-}C_5H_4N)\}_2$] (27.70 kcal mol$^{-1}$).[1] Similarly close values (21.8–41.2 kcal mol$^{-1}$, RB3LYP/DZVP level of theory) have been found for the activation barrier for the insertion of $Pd(PH_3)_2$ into the C–F bond of different fluoroarenes ($FC_6H_3XY$; X, Y = H, CN, $NO_2$).[23]

Table 3. $\Delta H$ [$E_{total}$(products) – $E_{total}$(reactants); kcal mol$^{-1}$] for reactions **I**–**VI** as well as activation barriers for these rearrangements ($E_{act}$; kcal mol$^{-1}$).

| Reaction | I | | II | III | IV | V | VI |
|---|---|---|---|---|---|---|---|
| | **20a → 21a** | **21a → 11a** | **22a → 12a** | **15a → 23a** | **16a → 24a** | **17a → 25a** | **18a → 26a** |
| $\Delta H$ | –28.72 | –26.67 | –22.86 | –26.07 | –31.87 | –9.82 | –9.36 |
| $E_{act}$ | 17.64 (**TSIa**) | 24.41 (**TSIIa**) | 20.30 (**TSIIIa**) | 46.77 (**TSIVa**) | 50.57 (**TSVa**) | 47.88 (**TSVIa**) | 46.23 (**TSVIIa**) |
| | **20b → 21b** | **21b → 11b** | **22b → 12b** | **15b → 23b** | **16b → 24b** | **17b → 25b** | **18b → 26b** |
| $\Delta H$ | –29.85 | –24.80 | –23.36 | –33.28 | –25.64 | –2.15 | –1.05 |
| $E_{act}$ | 24.64 (**TSIb**) | 29.02 (**TSIIb**) | 25.59 (**TSIIIb**) | 16.17 (**TSIVb**) | 31.00 (**TSVb**) | 36.17 (**TSVIb**) | 34.01 (**TSVIIb**) |

The computed barriers for the system without $N_{Py}$→M bonds [series (b)] are different from those previously discussed for species which contain $N_{Py}$→M contacts [series (a)]. While the values for reactions **20b** → **21b**, **21b** → **11b**, **22b** → **12b**, **17b** → **25b**, and **18b** → **26b** are close to those found previously (see Table 3), the barriers for reactions of indium species **15b** → **23b** and **16b** → **24b** are dramatically lower than those for reactions **15a** → **23a** and **16a** → **24a**.

Some general trends should be noted with regard to the calculated transition state geometries [series (a)]. First of all, the species are characterized by a considerable shortening of the M–F contacts in comparison with those found in reactants **15a**–**18a** and **20a**–**22a**, while the splitting bond (M–N or Sb–Hal) becomes elongated. Some elongation of the M–$N_{Py}$ distances in the TSs in comparison with those in the corresponding reactants should be mentioned, especially the significant alterations in **TSVIa** and **TSVIIa**.

A noticeable elongation of both C–C bonds (aromatic $C_6F_5$ ring) at the carbon atom involved in the rearrangement processes is also found for all TSs studied. The values of the nascent C–N bond lengths in **TS1a**–**TSVa** vary between 1.760 and 1.991 Å, while the corresponding covalent bonds in the products of reactions **I**–**IV** are 1.399–1.461 Å. Analogously, the values of the splitting C–F bond lengths in **TS1a**–**TSVa** vary between 1.482 and 1.565 Å, while the corresponding covalent bonds in the reactants of reactions **I**–**IV** are 1.348–1.356 Å. The F–C–N angles in **TS1a**–**TSVa** vary between 85.6 and 92.6°. The geometry of the transition states therefore allows us to define the proposed mechanism of the nucleophilic addition under study as a concerted oxidative addition.[11,24,25]

We believe that the main driving force behind the studied rearrangements is the formation of thermodynamically more favorable species. In the case of bismuth derivatives **20a**, **21a**, and **22a**, as well as the previously studied antimony compounds $[(Et_2N)_2Sb\{N(C_6F_5)(2\text{-}C_5H_4N)\}]$ and $[(Et_2N)Sb\{N(C_6F_5)(2\text{-}C_5H_4N)\}_2]$,[1] these interconversions proceed very easily as the weak $N_{Py}$→M contacts in these substances do not prevent M–F bond formation. In our opinion the rearrangement is likely to proceed through formation of a hypervalent fragment $C_{C_6F_5}$–F–Bi(Sb) with retention of the Bi(Sb)–$NR_2$ bond in **TS1a**–**TSIIIa**. Thus, the presence of additional electron density on the metal atom is necessary to decrease the activation barrier of the studied rearrangement.

In contrast, the indium derivatives **15** and **16** are stable and do not participate in any rearrangement processes due to the very strong $N_{Py}$→In interaction. The presence of this bond in indium derivatives increases the steric hindrance to the attack of the F atom at the In atom, although the indium center is more electron-deficient than in compounds without additional interactions. Both these factors prevent the rearrangement of **15** and **16** from occurring. This conclusion is confirmed by the decrease of the computational barrier found for **15b** → **23b** and **16b** → **24b** (compounds without $N_{Py}$→In contacts).

As regards reactions **V** and **VI**, we believe that the high barriers are caused by factors analogous to those previously mentioned for indium derivatives. The comparatively strong $N_{Py}$→Sb interaction along with the presence of five covalent bonds around the antimony atom in **17a** and **18a** prevent these Sb centers from participating in the supposed rearrangement. It should be noted, however, that the difference between the reactants and products in these reactions is not as large as in other reactions studied (Table 3).

## Conclusions

In an extension of our studies on antimony(III) amides we have investigated the transamination of pentafluoro(2-pyridyl)aniline with dialkylamides of bismuth(III), antimony(V), and indium(III). The reaction between $Bi(NMe_2)_3$ (**2**) and $HN(2\text{-}C_5H_4N)(C_6F_5)$ (**1**) affords the expected tris(amide) **10**, whereas replacement of only one or two $NMe_2$ groups leads to the isolation of the unexpected bismuth fluorides **11** and **12** as a result of an F↔$NMe_2$ metathesis. In contrast, the treatment of $[In(NEt_2)_3]_2$ (**2**) with the same amine **1** leads to the corresponding stable monomeric tris(amide)s **9**, **15**, or **16**. No F↔$NEt_2$ rearrangement occurs for **15** and **16**. Furthermore, antimony(V) amides such as **17** and **18** tend to be more stable with respect to this rearrangement than the antimony(III) amides reported previously. These examples show that the tendency to undergo this rearrangement increases with an increase of the covalent radius and decreases with an increase of coordination number of the central atom. This rearrangement also requires a highly polar M–N bond, therefore increasing the covalent character of the compound (e.g. by a higher oxidation state) decreases the likelihood of this metathesis to occur. Density functional calculations on the activation barriers of the studied reactions have been found to be in agreement with the experimental results. The steric demand of the substituents at the central atom as well as its electron deficiency are the crucial factors that define the stability of these tris(amide)s to F↔$NR_2$ or conceivable F↔Hal rearrangements.

## Experimental Section

**General Remarks:** All manipulations were performed under dry, oxygen-free argon using standard Schlenk techniques. All manipulations of Bi-containing compounds were carried out in brown glass equipment. Solvents were dried by standard methods and distilled prior to use. $Bi(NMe_2)_3$ (**2**),[26] $[In(NEt_2)_3]_2$ (**3**),[27] $Me_3SbBr_2$ (**7**),[28] and $Me_3SbCl_2$ (**8**)[29] were prepared according to the literature. $C_6D_6$ was obtained from Deutero GmbH and dried with sodium. $^1H$, $^{13}C$, and $^{19}F$ NMR spectra were recorded with Bruker ARX 200, AC 300, AMX 400, or DRX 500 spectrometers at 23 °C. Chemical shifts in the $^1H$ and $^{13}C$ NMR spectra are given in ppm relative to internal $Me_4Si$, and those in $^{19}F$ NMR experiments relative to $CFCl_3$ as an external standard. EI mass spectra were recorded with a Finnigan MAT CH7A device using electron impact ionization at 70 eV, and FD mass spectra were recorded with a Finnigan MAT 95S device; all assignments were made with reference to the most abundant isotopes. Elemental analyses were carried out by the Fachbereich Chemie of the Philipps University

Marburg (Heraeus-Rapid-Analyzer). The nonempirical generalized gradient approximation (GGA) for the exchange-correlation functional of Perdew et al. (PBE) was employed in this work.[30,31] All calculations were performed using the program PRIRODA developed by Laikov,[32] which implements an economical computational procedure. The one-electron wavefunctions were expanded in the extended TZ2P atomic basis sets of the contracted Gaussians {311/1} for H, {611111/411/11} for C, N, and F, {6111111111/611111/11} for Cl, {6111111111111/5111111111/51111} for Br, {711111111111111/611111111111/51111111} for In and Sb, and {24,24,24,24,24,24,24,24/22,22,22,22,22,22,22,22/15,15,15,15,15/9} for Bi. Full geometry optimization was performed by DFT-PBE methods for a number of structures followed by vibrational frequency calculation using analytical first and second derivatives. Each structure was characterized by a vibrational analysis. Each transition state has only one imaginary normal mode and equilibrium geometry states have only real normal modes. An IRC (intrinsic reaction coordinate) calculation was run starting from the transition state geometry in both directions and verified initial and final structures linked to the transition state. The present theoretical method has been used, and has given very useful results, in antimony and bismuth chemistry.[22]

**Synthesis of (2-$C_5H_5N$)($C_6F_5$)NH (1):** *n*-Butyllithium (1.6 M in hexane, 325 mL, 0.52 mol) was added dropwise to a stirred solution of 2-aminopyridine (48.94 g, 0.52 mol) in thf (50 mL) at –78 °C. The reaction mixture was warmed to 25 °C and stirred at room temperature for 4 h, and then all volatiles were removed under reduced pressure; thf (300 mL) was added to the residue, and then a solution of $C_6F_6$ (48.36 g, 0.26 mol) in thf (60 mL) was added dropwise at –45 °C over about 1 h. The reaction mixture was warmed to room temperature and refluxed for a further 24 h. Dilute hydrochloric acid was then carefully added to the reaction mixture to pH = 4. The organic phase was washed twice with dilute hydrochloric acid (100 mL), and the combined aqueous phases were extracted with diethyl ether (2 × 100 mL). All organic phases were combined and dried with $Na_2SO_4$, and all volatiles were removed under reduced pressure. The residue was extracted with hot *n*-heptane, and crystallized crude **1** was purified by sublimation (50 °C/$5 \times 10^{-3}$ bar). Colorless crystals. Yield: 60.72 g (90%). EI-MS: *m*/*z* (%) = 260 (42) [$M^+$], 241 (100) [$M^+$ – F]. $^1$H NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 5.99 (m, 1 H), 6.36 (m, 1 H), 6.84 (br. s, 1 H, NH), 6.98 (m, 1 H), 8.07 (m, 1 H) ppm. $^{13}$C NMR ($C_6D_6$, 50.32 MHz): $\delta$ = 108.45, 116.25, 137.78, 148.29, 155.29 (all carbon atoms of pyridyl groups) ppm; 4 signals for the carbon atoms of the $C_6F_5$ group were not observed in the spectrum. $^{19}$F NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –164.07 (t, 2 F), –161.80 (t, 1 F), –147.27 (d, 2 F) ppm.

**Synthesis of 2-$C_5H_5N$($C_6F_5$)NLi·thf (4·thf):** *n*-Butyllithium (1.6 M in hexane, 22.50 mL, 36.00 mmol) was added dropwise to a stirred solution of **1** (9.33 g, 35.88 mmol) in thf (50 mL) at –78 °C. The reaction mixture was warmed to 25 °C and stirred at room temperature for 5 h, and then all volatiles were removed under reduced pressure to give a white solid. The crude product was washed with cold *n*-pentane (3 × 10 mL) and dried under reduced pressure. Yield: 11.03 g (91%). White solid. $C_{15}H_{12}F_5LiN_2O$ (338.20): calcd. C 53.27, H 3.58, N 8.28; found C 52.94, H 3.50, N 8.03. $^1$H NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 1.02–1.08 (m, 4 H, O-$CH_2$-$CH_2$), 3.20–3.26 (m, 4 H, O-$CH_2$), 6.16–6.27 (m, 2 H), 6.97–7.06 (m, 1 H), 7.84 (br. s, 1 H) ppm. $^{19}$F NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –173.52 (br. s, 1 F), –166.15 (t, F), –155.10 (br. s, 2 F) ppm. $^{19}$F NMR (thf, 188.28 MHz): $\delta$ = –179.22 (t, 1 F), –170.14 (t, 2 F), –153.64 (d, 2 F) ppm.

**Synthesis of [(2-$C_5H_4N$)($C_6F_5$)N]$_3$Bi (10). Method a:** A solution of amine **1** (0.76 g, 2.90 mmol) in toluene (10 mL) was added dropwise at 0 °C to a stirred solution of **2** (0.33 g, 0.97 mmol) in toluene (10 mL). The reaction mixture was stirred at room temperature for 12 h, and all volatiles were removed under reduced pressure. The residue was recrystallized from *n*-pentane (–30 °C) to give **10** as a yellow solid. Yield: 0.78 g (82%). **Method b:** A solution of **4**·thf (1.67 g, 4.96 mmol) in thf (15 mL) was added dropwise to a stirred suspension of $BiCl_3$ (0.52 g, 1.65 mmol) in thf (20 mL) at 0 °C. The reaction mixture was stirred for a further 12 h, and then all volatiles were removed under reduced pressure. *n*-Pentane (30 mL) was added to the residue, and insoluble substances were removed by filtration. The solution was reduced in volume to 20% of the original volume and stored at –30 °C to obtain **10** as a yellow solid. Yield: 1.20 g (74%). $C_{33}H_{12}BiF_{15}N_6$ (986.45): calcd. C 40.18, H 1.23, N 8.52; found C 39.79, H 1.43, N 8.03. EI-MS: *m*/*z* (%) = 727 (28) [M – N($C_5H_4N$)($C_6F_5$)]$^+$. $^1$H NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 5.58 (br. s, 3 H), 6.14 (br. s, 3 H), 6.93–7.02 (m, 3 H), 7.89 (br. s, 3 H) ppm. $^{13}$C NMR ($C_6D_6$, 50.32 MHz): $\delta$ = 107.96, 112.33, 140.96, 144.17 ppm; 4 signals for the carbon atoms of the $C_6F_5$ group and 1 signal for a carbon atom of the pyridyl group were not observed in the spectrum. $^{19}$F NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –164.80 (br. s, 6 F), –162.64 (br. s, 3 F), –146.86 (d, 6 F) ppm.

**Synthesis of 11:** A solution of **1** (0.86 g, 3.3 mmol) in toluene (20 mL) was added dropwise to a stirred solution of **2** (1.15 g, 3.3 mmol) in toluene (15 mL) at –78 °C. The reaction mixture was stirred at room temperaturefor 24 h, and all volatiles were then removed under reduced pressure. The residue was recrystallized from *n*-pentane (–30 °C) to give **11** as a yellow solid. Yield: 1.21 g (66%). $C_{15}H_{16}BiF_5N_4$ (506.13): calcd. C 32.39, H 2.90, N 10.07; found C 31.27, H 2.98, N 9.20. FD-MS: *m*/*z* (%) = 519 (32) [$M^+$ – 2 F + H], 518 (20) [$M^+$ – 2 F]. $^1$H NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 2.37, 2.38 (2 s, 12 H, $NMe_2$) 5.70 (m, 1 H), 6.00 (m, 1 H), 6.98 (m, 1 H), 7.63 (m, 1 H) ppm. $^{19}$F NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –164.39 (br. s, 2 F, $F_2Bi$), –163.25 (t, 1 F), –149.50 (d, 2 F) ppm.

**Synthesis of 12:** A solution of **1** (0.62 g, 2.4 mmol) in toluene (10 mL) was added dropwise to a stirred solution of **2** (0.43 g, 1.3 mmol) in toluene (10 mL) at –78 °C. The reaction mixture was stirred at room temperature for 24 h, and then all volatiles were removed under reduced pressure. The residue was recrystallized from *n*-pentane (–30 °C) to give **12** as a yellow solid. Yield: 0.56 g (58%). $C_{24}H_{14}BiF_{10}N_5$ (771.37): calcd. C 37.37, H 1.83, N 9.08; found C 36.09, H 2.08, N 8.22. EI-MS: *m*/*z* (%) = 771 (1) [$M^+$]. FD-MS: *m*/*z* (%) = 772 (0.5) [$M^+$ + H], 771 (0.5) [$M^+$], 752 (2) [$M^+$ – F]. $^1$H NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 2.24, 2.25 (2 s, 6 H, Me), 5.83 (m, 1 H), 6.04 (m, 1 H), 6.10 (m, 1 H), 6.39 (m, 1 H), 7.02 (m, 1 H), 7.06 (m, 1 H), 7.57 (m, 1 H), 7.75 (m, 1 H) ppm. $^{19}$F NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –165.42 (t, 2 F), –165.26 (t, 1 F), –163.90 (t, 1 F), –162.96 (t, 1 F), –151.19 (d, 1 F), –146.70 (t, 2 F), –146.87 (br. s, 1 F, FBi), –142.78 (d, 1 F) ppm.

**Synthesis of 13:** Water (2 mL) was added dropwise to a stirred solution of **11** (0.72 g, 1.3 mmol) in toluene (10 mL), and the reaction mixture was stirred for 12 h. The organic phase was separated, dried with $Na_2SO_4$, and all volatiles were removed under reduced pressure. The residue was recrystallized from *n*-heptane (2 mL) to give **13** as a colorless solid. Yield: 0.26 g (65%). $C_{15}H_{17}F_3N_4$ (310.32): calcd. C 58.06, H 5.52, N 18.05; found C 57.63, H 4.09, N 17.64. EI-MS: *m*/*z* (%) = 310 (100) [$M^+$]. $^1$H NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 2.43, 2.44 (2s, 12 H, $NMe_2$), 6.12 (m, 1 H), 6.45 (m, 1 H), 7.06 (m, 1 H), 8.22 (m, 1 H) ppm. $^{13}$C NMR ($C_6D_6$, 50.32 MHz): $\delta$ = 42.49, 42.59 ($NMe_2$), 109.17, 115.56, 136.52, 148.57, 155.44 ppm; 4 signals for the carbon atoms of $C_6F_5$ and 1

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

signal for a carbon atom of the pyridyl group were not observed in the spectrum. $^{19}F$ NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –166.28 (t, 1 F), –150.42 (d, 2 F) ppm.

**Synthesis of 14:** Water (2 mL) was added dropwise to a stirred solution of **12** (0.43 g, 0.6 mmol) in toluene (10 mL), and the reaction mixture was stirred for 12 h. The organic phase was separated, dried with $Na_2SO_4$, and all volatiles were removed under reduced pressure. The residue was purified by chromatography ($SiO_2$; *n*-heptane/toluene (5:1), 30 mL) to give **14** as a colorless solid. Yield: 0.07 g (41%). $C_{13}H_{11}F_4N_3$ (285.24): calcd. C 54.74, H 3.89, N 14.73; found C 54.46, H 3.61, N 14.93. EI-MS: *m*/*z* (%) = 285 (100) [$M^+$]. $^1H$ NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 2.25, 2.26 (2s, 6 H, $NMe_2$), 6.17 (m, 1 H), 6.38 (m, 1 H), 7.01 (m, 1 H), 8.16 (m, 1 H) ppm. $^{13}C$ NMR ($C_6D_6$, 50.32 MHz): $\delta$ = 43.00, 43.09 ($NMe_2$), 108.74, 116.23, 137.53, 148.60, 155.90 ppm. $^{19}F$ NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –165.26 (t, 1 F), –162.93 (t, 1 F), –151.18 (d, 1 F), –142.78 (d, 1 F) ppm.

**Synthesis of 15:** A solution of amine **1** (0.30 g, 1.15 mmol) in toluene (10 mL) was added dropwise at –78 °C to a stirred solution of **3** (0.38 g, 0.58 mmol) in toluene (10 mL). The reaction mixture was stirred at room temperature for 12 h, and all volatiles were removed under reduced pressure. The residue was recrystallized from *n*-pentane (–30 °C) to give **15** as a yellow solid. Yield: 0.52 g (87%). $C_{19}H_{24}F_5InN_4$ (518.23): calcd. C 44.04, H 4.67, N 10.81; found C 43.57, H 4.41, N 10.04. EI-MS: *m*/*z* (%) = 374 (15) [M – 2 $NEt_2$]$^+$. $^1H$ NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 0.97 (t, 12 H, $CH_3$), 2.48 (q, 8 H, $NCH_2$), 5.89–6.01 (m, 2 H), 6.78–6.86 (m, 1 H), 7.52–7.54 (m, 1 H) ppm. $^{13}C$ NMR ($C_6D_6$, 50.32 MHz): $\delta$ = 15.61 ($CH_3$), 44.18 ($NCH_2$), 107.96, 112.33, 140.96, 144.17 ppm; four signals for the carbon atoms of the $C_6F_5$ group and one signal for a carbon atom of the pyridyl group were not observed in the spectrum. $^{19}F$ NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –165.63 (t, 1 F), –164.77 (t, 2 F), –149.89 (d, 2 F) ppm.

**Synthesis of 16:** The procedure was analogous to that used to synthesize **15**. Thus, treatment of a solution of **1** (1.46 g, 5.60 mmol) in toluene (10 mL) with a solution of **3** (1.46 g, 5.60 mmol) in toluene (10 mL) gave **16** as a light yellow solid. Yield: 1.46 g (74%). $C_{26}H_{18}F_{10}InN_5$ (705.26): calcd. C 44.28, H 2.57, N 9.93; found C 43.52, H 2.61, N 9.49. EI-MS: *m*/*z* (%) = 633 (76) [M – $NEt_2$]$^+$. $^1H$ NMR ($C_6D_6$, 300.13 MHz): $\delta$ = 0.68 (t, 6 H, $CH_3$), 3.29 (br. s, 4 H, $NCH_2$), 5.80–5.83 (m, 2 H), 6.09–6.13 (m, 2 H), 6.90–6.95 (m, 2 H), 7.47–7.49 (m, 2 H) ppm. $^{13}C$ NMR ($C_6D_6$, 75.47 MHz): $\delta$ = 12.10 ($CH_3$), 41.15 ($NCH_2$), 107.74, 110.81, 140.45, 144.27, 162.82 ppm; 4 signals for the carbon atoms of the $C_6F_5$ group were not observed in the spectrum. $^{19}F$ NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –164.74 (t, 2 F), –163.37 (t, 4 F), –147.14 (d) ppm.

**Synthesis of 9:** A solution of amine **1** (1.87 g, 7.20 mmol) in toluene (10 mL) was added dropwise at room temperature to a stirred solution of **3** (0.80 g, 1.20 mmol) in toluene (10 mL). The reaction mixture was stirred for 12 h, and all volatiles were removed under reduced pressure. The residue was recrystallized from *n*-pentane (–30 °C) to give **9** as colorless crystals. Yield: 2.00 g (93%). $C_{33}H_{12}F_{15}InN_6$ (892.28): calcd. C 44.42, H 1.36, N 9.42; found C 44.20, H 1.27, N 8.86. EI-MS: *m*/*z* (%) = 892 (79) [M]$^+$, 633 (63) [M – N($C_5H_4N$)($C_6F_5$)]$^+$, 374 (10) [M – 2 N($C_5H_4N$)($C_6F_5$)]$^+$. $^1H$ NMR ($C_6D_6$, 300.13 MHz): $\delta$ = 5.92–5.95 (m, 3 H), 5.99–6.03 (m, 3 H), 6.80–6.86 (m, 3 H), 7.56–7.58 (m, 3 H) ppm. $^{13}C$ NMR ($C_6D_6$, 75.47 MHz): $\delta$ = 108.05, 112.69, 140.89, 144.41 ppm; 4 signals for the carbon atoms of the $C_6F_5$ group and 1 signal for a carbon atom of the pyridyl group were not observed in the spectrum. $^{19}F$ NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –165.28 (br. s, 3 F), –164.66 (t, 6 F), –149.54 (br. s, 6 F) ppm.

**Synthesis of 17:** A solution of **4**·thf (1.64 g, 4.84 mmol) in thf (20 mL) was added dropwise at room temperature to a stirred solution of **7** (1.58 g, 4.84 mmol) in thf (15 mL). The reaction mixture was stirred at room temperature for 48 h, and all volatiles were removed under reduced pressure. Toluene (30 mL) was added to the residue, and insoluble substances were removed by filtration. The solution was reduced in volume to 5 mL and stored at –30 °C to obtain **17** as a white solid. Yield: 1.71 g (70%). $C_{14}H_{13}BrF_5N_2Sb$ (505.92): calcd. C 33.24, H 2.59, N 5.54; found C 33.05, H 2.51, N 5.33. EI-MS: *m*/*z* (%) = 506 (2) [M]$^+$, 247 (100) [M – N($C_5H_4N$)($C_6F_5$)]$^+$. $^1H$ NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 1.79 (s, 9 H, $SbMe_3$), 5.55–5.59 (m, 1 H), 6.20–6.27 (m, 1 H), 6.85–6.94 (m, 1 H), 7.58–7.61 (m, 1 H) ppm. $^{13}C$ NMR ($C_6D_6$, 50.32 MHz): $\delta$ = 20.83 ($SbMe_3$), 106.31, 113.53, 138.57, 146.21, 159.07 ppm; 4 signals for the carbon atoms of the $C_6F_5$ group were not observed in the spectrum. $^{19}F$ NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –162.18 (t, 2 F), –157.64 (t, 1 F), –147.22 (d, 2 F) ppm.

**Synthesis of 18:** The procedure was analogous to that used to synthesize **17**. Thus, treatment of a solution of **4**·thf (1.10 g, 3.24 mmol) in thf (20 mL) with a solution of **8** (0.77 g, 3.24 mmol) in thf (15 mL) gave **18** as a white solid. Yield: 1.15 g (77%). $C_{14}H_{13}ClF_5N_2Sb$ (461.47): calcd. C 36.44, H 2.84, N 6.07; found C 36.21, H 2.71, N 5.72. FD-MS: *m*/*z* (%) = 462 (1) [M]$^+$, 384 (100) [M – $C_5H_4N$]$^+$. $^1H$ NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 1.67 (s, $SbMe_3$), 5.56–5.61 (m, 1 H), 6.21–6.28 (m, 1 H), 6.86–6.95 (m, 1 H), 7.63–7.64 (m, 1 H) ppm. $^{13}C$ NMR ($C_6D_6$, 50.32 MHz): $\delta$ = 19.95 ($SbMe_3$), 106.80, 113.63, 138.58, 146.43, 158.78 ppm; 4 signals for the carbon atoms of the $C_6F_5$ group were not observed in the spectrum. $^{19}F$ NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –162.31 (t, 2 F), –158.10 (t, 1 F), –147.31 (d, 2 F) ppm.

**Synthesis of 19:** The procedure was analogous to that used to synthesize **17**. Thus, treatment of a solution of **4**·thf (2.64 g, 7.80 mmol) in thf (20 mL) with a solution of **8** (0.93 g, 3.90 mmol) in thf (15 mL) gave **19** as a white solid (extraction with *n*-pentane). Yield: 1.95 g (73%). $C_{25}H_{17}F_{10}N_4Sb$ (685.17): calcd. C 43.82, H 2.50, N 8.18; found C 43.58, H 2.35, N 7.66. EI-MS: *m*/*z* (%) = 669 (1) [M – Me]$^+$, 425 (100) [M – N($C_5H_4N$)($C_6F_5$)]$^+$. $^1H$ NMR ($C_6D_6$, 200.13 MHz): $\delta$ = 1.29 (br. s, $SbMe_3$), 5.96–6.00 (m, 2 H), 6.31–6.37 (m, 2 H), 6.94–7.02 (m, 2 H), 8.04–8.06 (m, 2 H) ppm. $^{13}C$ NMR ($C_6D_6$, 50.32 MHz): $\delta$ = 19.76 ($SbMe_3$), 106.80, 112.48, 138.49, 146.29, 159.51 ppm; 4 signals for the carbon atoms of the $C_6F_5$ group were not observed in the spectrum. $^{19}F$ NMR ($C_6D_6$, 188.28 MHz): $\delta$ = –164.27 (t, 4 F), –161.72 (t, 2 F), –146.97 (d, 4 F) ppm.

**X-ray Crystallographic Study. Crystal Data for 9·0.5$C_7H_8$:** Triclinic unit cell, space group $P\bar{1}$, with $a$ = 10.7275(8), $b$ = 12.9882(8), $c$ = 14.4190(10) Å, $\alpha$ = 72.264(8), $\beta$ = 79.030(9), $\gamma$ = 69.388(8)°, $V$ = 1783.2(2) Å$^3$, $Z$ = 2. 17664 reflections were collected at 193 K with a STOE IPDS diffractometer using graphite-monochromated Mo-$K_\alpha$ radiation and were corrected for absorption. 6471 reflections were unique ($R_{int}$ = 0.0517) and 4274 with $I > 2\sigma(I)$ "observed". The structure was solved by direct methods[33] and refined using the full-matrix least-squares procedure.[34] All non-hydrogen atoms were treated anisotropically, and hydrogen atoms were treated with fixed isotropic thermal parameters as "riding" on calculated positions. One molecule of disordered toluene is present in the unit cell and was refined with restraints for geometrical and thermal parameters. Final residuals for 540 refined parameters and 70 restraints: $wR2$ = 0.053 (for all unique data), $R1$ = 0.0314 (for the "observed" data). CCDC-631484 (**9**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# Optical, Magnetic and Structural Properties of the Spin-Crossover Complex $[Fe(btr)_2(NCS)_2]\cdot H_2O$ in the Light-Induced and Thermally Quenched Metastable States

**Vincent Legrand,[a,b] Sébastien Pillet,[a] Chiara Carbonera,[c] Mohamed Souhassou,[a] Jean-François Létard,[c] Philippe Guionneau,[c] and Claude Lecomte*[a]**

**Keywords:** Iron(II) / Photoswitching / Structural analysis / Photomagnetism / Spin crossover

$[Fe(btr)_2(NCS)_2]\cdot H_2O$ [btr = 4,4′-bis(1,2,4-triazole)] is the archetype of highly cooperative and low-dimensional spin-crossover complexes, which exhibit low-spin (LS) to high-spin (HS) light-induced conversion at very low temperature. The structural reorganizations related to the light-induced and thermally induced LS–HS transitions were characterized by single-crystal X-ray diffraction below the relaxation temperature ($T$ = 15 K < $T_{LIESST}$) and at 130 K within the thermal hysteresis loop. We show that the LIESST and thermal spin transitions lead to the same structural variations, namely an elongation of the Fe–N bonds by 0.18 Å (Fe–$N_{NCS}$) and 0.20 Å (Fe–$N_{btr}$), on going from LS to HS, together with a reorientation of the NCS group by nearly 13°. The atomic displacement amplitudes, derived from the crystal structures, indicate lattice vibration modes of larger amplitudes and correlatively lower vibration frequencies in the HS state. The deformation of the crystal lattice as a function of temperature and laser excitation was quantitatively analyzed in terms of the HS and LS thermal-expansion ($\boldsymbol{\alpha}_{HS}$ and $\boldsymbol{\alpha}_{LS}$) and spin-transition spontaneous-strain ($\boldsymbol{\varepsilon}$) tensors. The eigendirections and eigenvalues of the $\boldsymbol{\alpha}$ and $\boldsymbol{\varepsilon}$ tensors correlate well with the weak and strong interactions in the solid and are responsible for the high cooperativity and low-dimensional behaviour. Magnetic and spectroscopic measurements were performed in all the different spin states and related to the structural findings.

## Introduction

Spin crossover in iron(II) coordination complexes is a quite well-understood phenomenon, which has been thoroughly described and reviewed in the literature.[1] The spin conversion is related to the change in the electronic configuration of iron from $t_{2g}^4e_g^2$ in the high-spin (HS) state to $t_{2g}^6e_g^0$ in the low-spin (LS) state on decreasing temperature. This HS→LS electron redistribution in general parallels drastic structural modifications, namely a contraction of the Fe–ligand bonds by typically 0.2 Å as well as a decrease in the distortion of the Fe octahedral coordination polyhedron.[2] Correlatively, a decrease in the molecular volume by several $Å^3$ is usually characterized. Spin-crossover complexes can furthermore change their spin state upon the variation of a thermodynamic parameter such as temperature or pressure or by the application of a perturbation like an intense magnetic field[3] or light irradiation.[1] In the latter case, the process leading to the LS→HS conversion is reversible[4] and is called the LIESST effect (Light Induced Excited Spin State Trapping).[5] The relaxation from the light-induced metastable HS state to the thermodynamically stable LS state is attributed to a tunnel mechanism at very low temperature and to a much faster thermal activation over an energy barrier at higher temperature. Accordingly, the metastable HS state can be trapped at very low temperature. Recently, it has been shown that an elegant way to characterize the photomagnetic properties is to measure the $T_{LIESST}$ temperature, which somewhat represents the temperature at which the metastable state relaxes quickly.[6,7] For weakly cooperative systems, the relaxation obeys single-exponential kinetics, whereas in the case of high cooperativity, the relaxation rate follows sigmoidal kinetics, ascribed to an autoaccelerated phenomenon owing to the HS→LS large molecular volume change and long-range elastic interactions in the solid.[8]

The structural aspects of spin-crossover complexes, and especially their relationship with respect to the spin transition characteristics, are nowadays raising a renewed interest. Direct correlations do exist between the distortion of the iron coordination octahedron and the features of the spin transition (e.g. $T_{LIESST}$).[9] Careful investigations of the structural modifications occurring during the thermal spin transition were reported in the literature and were mostly

based on the comparison between the crystal structures in the HS state at room temperature and in the LS state at low temperature. Obviously, such studies suffer from thermal contraction effects, rendering a quantitative analysis quite meaningless if one wants to investigate fine structural details. In addition, atomic displacement parameters are not comparable between room temperature and low temperature; significant corrections to bond lengths would therefore also be required from libration motion.[10] The perturbation due to thermal contraction effects can be estimated, in a first approximation, by using isostructural materials which do not undergo the spin transition, e.g. by exchanging the central transition-metal ion.[11] A better strategy would take advantage of a hysteresis loop, if any, centred on the thermal spin transition, to derive the crystal structure in both the HS and LS states at identical temperature. For almost a decade, the crystal structures of light-induced metastable HS states have been reported for an increasing number of systems; they were derived from X-ray or neutron diffraction measurements performed at very low temperatures under light excitation.[12] These studies are possible thanks to the slowing of the HS to LS relaxation rate at very low temperature.[8] In some cases, a metastable HS state can also be trapped by rapid thermal quenching from room temperature to very low temperature: for example, the HS crystal structure of $[Fe(PM–BiA)_2(NCS)_2]$ (PM = *N*-2′-pyridylmethylene and BiA = 4-aminobiphenyl) was determined at 30 K.[13] Following previous notations, the metastable HS state is denoted by HS-2 from this point onwards in this paper (HS-2q and HS-2p are used for the thermally quenched and photoinduced states, respectively); the HS state above the thermal transition is denoted by HS-1 (Figure 1). Finally, very recently, high-resolution X-ray diffraction measurements on the spin-crossover compounds $[Fe(btr)_2(NCS)_2]\cdot H_2O$ [btr = 4,4′-bis(1,2,4-triazole)] and $[Fe(phen)_2(NCS)_2]$ (phen = 1,10-phenanthroline) have shown the possibility of the modelling of the electron-density distribution and the characterization of its redistribution upon spin transition, for instance, over the iron 3d atomic orbitals.[14–16] Whether the HS-2 states are identical within each other and how they compare to the HS-1 state are still controversial topics. In some cases, it has been proved that HS-2p and HS-2q are structurally different from HS-1 without any ambiguity, for instance in $[Fe(abpt)_2(N(CN)_2)_2]$,[17] leading to the concept of multimetastability.[18]

$[Fe(btr)_2(NCS)_2]\cdot H_2O$ is the archetype of highly cooperative spin-crossover compounds. It exhibits abrupt thermal spin transitions with a 21-K hysteresis loop ($T_{1/2\downarrow}$ = 123.5 K and $T_{1/2\uparrow}$ = 144.5 K). This complex crystallizes in the monoclinic space group *C*2/*c* without any symmetry change at the thermal spin transition. The crystal structure consists of an $Fe^{II}$ ion located in a slightly distorted $FeN_6$ centrosymmetric octahedral environment with four btr groups in the basal plane and two *trans* thiocyanate ligands in the apical directions (Figure 2). The btr group is a bidentate ligand leading to a bidimensional extended layer structure parallel to the *bc* plane. The NCS anions are directed away from the layers. The connection in the third direction is provided through van der Waals interactions and assisted by weak hydrogen bonds through a noncoordinated water molecule. On the basis of this specific polymeric layer structure, one might expect high cooperative interactions in the *bc* plane. The crystal structure was determined above and below the thermal transition at 293 K in the HS state[19] and at 104 K in the LS state.[20] The major structural modifications related to this transition are a shortening of the Fe–N bond lengths [$\Delta d_{Fe–NCS}$ = –0.175(4) Å, $\Delta d_{Fe–N(btr)}$ = –0.213(3) Å] and a reorientation of the NCS groups with a more linear Fe–N–C–S geometry in the LS state in parallel to a contraction of the unit cell by 4.8% [$\Delta V$ = –91(9) Å$^3$]. This system has been the subject of various studies at the thermal spin transition. The hysteresis loop has been followed by magnetic measurements and Mössbauer spectroscopy.[19] The effect of metal dilution was analyzed in $[Fe_xM_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ (M = Co, Ni) mixed systems, by calorimetric, magnetic and Mössbauer measurements;[21] these studies showed that metal dilution smoothes the transition curves. The first studies of the metastable HS state were performed through reflectivity and magnetic measurements on $[Fe_xCo_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ derivatives;[22] the authors studied the LIESST relaxation and the LITH (Light Induced Thermal Hysteresis) loop under permanent irradiation at $\lambda$ = 600 nm and 40 mW cm$^{-2}$. Finally, it has been shown that the HS ↔ LS transition is related to a domain nucleation, growth and coarsening process in the solid state, with an unprecedented light-induced structural reorganization.[20,23]

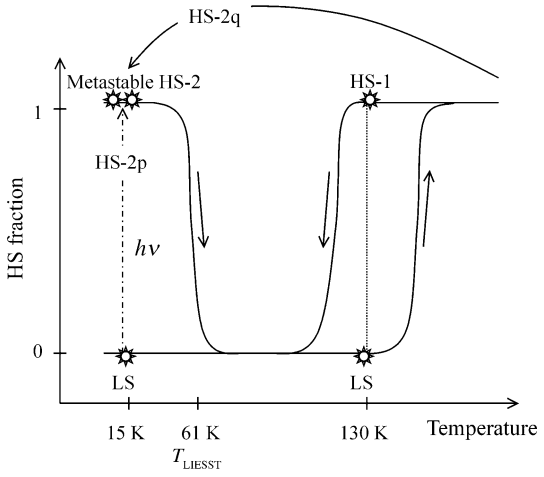

Figure 1. Schematic structural phase diagram (see text for the phase labelling).

We report here a detailed structural analysis of $[Fe(btr)_2(NCS)_2]\cdot H_2O$ in various spin states, HS-1, LS, HS-2q, HS-2p, by using X-ray diffraction measurements performed at two temperatures, 15 K and 130 K (Figure 1). The main goal of this study is the characterization of the structural reorganization related to the light-induced and thermally induced spin transitions independent of thermal contraction/expansion effects. Our structural findings are correlated to magnetic and spectroscopic results, which allows us

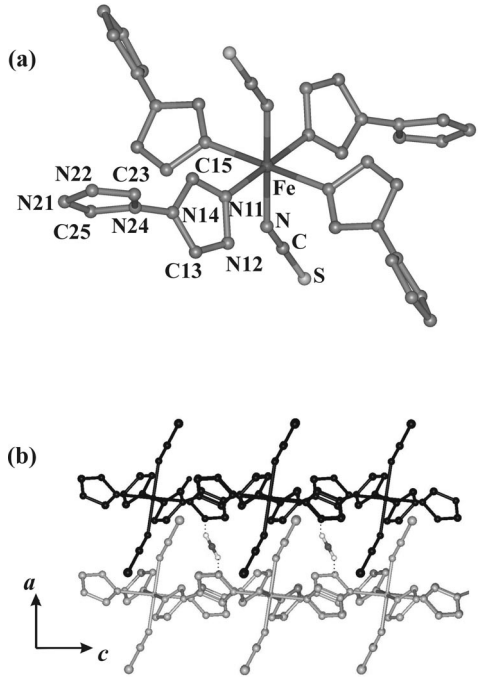

Figure 2. (a) Molecular structure of $[Fe(btr)_2(NCS)_2]\cdot H_2O$ in the HS-2q state at 15 K. (b) View of the layer stacking along the *a* axis. Hydrogen atoms of the btr groups are omitted for clarity.

to define the appropriate experimental conditions for the photocrystallographic measurements. We must emphasize that, for consistency, single crystals of similar quality and size were used in all the experiments reported here.

## Results and Discussion

### Optical Spectroscopy

$[Fe(btr)_2(NCS)_2]\cdot H_2O$ exhibits thermochromic effects associated with the HS–LS transition, from colourless at room temperature to pink at low temperature. The change in the diffuse absorption spectrum as a function of temperature is given in Figure 3. On decreasing the temperature from 160 K to 100 K and passing through the thermal HS-to-LS transition, the absorption band with a maximum intensity at 550 nm (18200 $cm^{-1}$) increases in intensity. This band is characteristic of the LS state and is attributed to the spin-allowed $^1A_1 \rightarrow {}^1T_1$ transition, according to the Tanabe–Sugano diagram for $Fe^{II}$ ($d^6$) in an octahedral ligand field. In parallel, the band with a maximum intensity at 875 nm (11400 $cm^{-1}$), characteristic of the HS state and corresponding to the $^5T_2 \rightarrow {}^5E$ transition, decreases in intensity. Below nearly 75 K, the 550-nm absorption band is gradually attenuated to a minimum value at 10 K owing to the partial LS-to-HS phototransformation under the probing white beam ("LITH down" in Figure 3). On further increasing the temperature to 100 K, first the 550-nm absorption band remains almost constant and in a second step increases in intensity, corresponding to the relaxation from HS to LS ("LITH up" in Figure 3). Finally, from 100 K to 160 K, the LS-to-HS thermal transition occurs, the 550-nm absorption band is attenuated and recovers its initial value. In such diffuse absorption measurements, the intensity ratio of the $^5T_2 \rightarrow {}^5E$ and $^1A_1 \rightarrow {}^1T_1$ bands should not be taken too strictly, because they may change owing to powder sample texture effects; therefore, they cannot be directly compared to single-crystal absorption spectra. In addition, a slight bleaching of the powder sample, resulting possibly from surface dehydration, has been noticed at the end of the measurement, which could alter the intensity of the $^5T_2 \rightarrow {}^5E$ band. It is indeed known that dehydrated $[Fe(btr)_2(NCS)_2]\cdot H_2O$ loses its spin-transition behaviour and is a HS system.

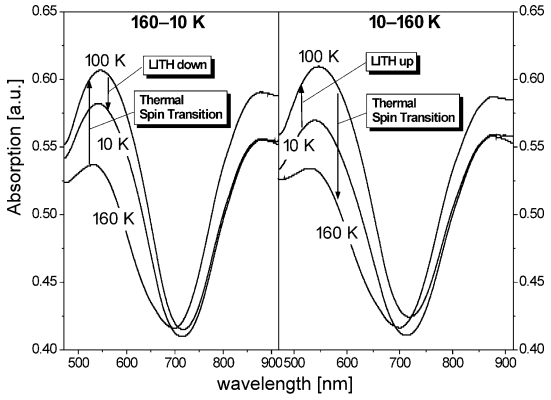

Figure 3. Diffuse absorption spectra as a function of temperature in the cooling (160–10 K) and warming (10–160 K) modes. The 10-K spectrum corresponds to the photostationary state under the experimental conditions of the reflectivity measurements.

This 550-nm absorption band displays a high contrast depending on the spin state. The diffuse reflected intensity vs. temperature at the wavelength $\lambda$ = 532 nm was thus investigated in more detail and is given in Figure 4. The thermal hysteresis loop is well defined with $T_{1/2\downarrow}$ = 123 K and $T_{1/2\uparrow}$ = 144 K, in perfect agreement with magnetic and crystallographic results.[19,20] On decreasing the temperature from 75 to 10 K, we observe an increase in the reflectivity signal, corresponding to partial LS-to-HS conversion induced by the probing white light. Then, as the temperature is increased further, the signal presents a constant plateau till nearly 62 K, at which the LS value is recovered. This loop, defined below 75 K, corresponds to the light-induced thermal hysteresis phenomenon (LITH),[24] already discussed by Desaix et al.,[22] and clearly confirms the existence of a photoinduced instability for $[Fe(btr)_2(NCS)_2]\cdot H_2O$. By comparison of the reflectivity value at the photostationary state (0.43) with those obtained for the purely LS (0.39) and purely HS (0.46) states, we can estimate a surface photoconversion, $\gamma_{HS}$, of nearly 0.5 at saturation.

The spin selectivity of the bands centred at 550 nm and 875 nm indicates that they correspond to the optimum laser wavelengths for inducing the LS-to-HS-2 (LIESST) and HS-2-to-LS (reverse LIESST) conversions, respectively. This information is crucial for defining the excitation conditions for the photocrystallographic measurements.

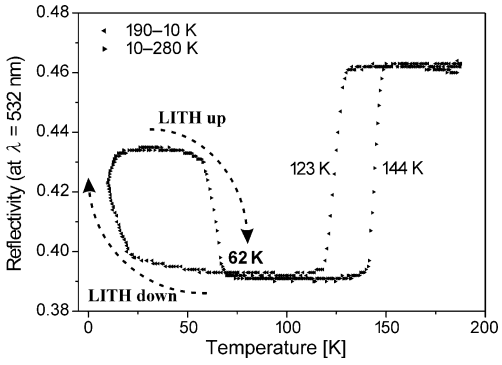

Figure 4. Reflectivity measurements as a function of temperature at $\lambda$ = 532 nm in the cooling (190–10 K) and warming (10–280 K) modes: $T_{1/2\downarrow}$ = 123 K, $T_{1/2\uparrow}$ = 144 K.

### Magnetic Behaviour of the Light-Induced and Thermally Induced Metastable States

The magnetic properties as a function of temperature and light irradiation were investigated by using different measurement procedures. For the first measurement (Figure 5a), the sample was rapidly quenched to 10 K in the HS-2q state. Then, the temperature was raised in the dark; $\chi_M T$ initially increases slightly, as a result of zero-field splitting of the quintet HS-2 state, before reaching a plateau and then sharply falls off to 0 $cm^3 K mol^{-1}$ at 61 K, indicating a complete relaxation of the molecular species into the LS state. After the relaxation, the thermal transitions were recorded in the warming and cooling modes and are consistent with literature results:[19] very abrupt and complete transitions at $T_{1/2\downarrow}$ = 123.5 K and $T_{1/2\uparrow}$ = 144.5 K. The $\chi_M T$ value at low temperature on the plateau is nearly identical (3.5 $cm^3 K mol^{-1}$) to that observed at high temperature in the HS-1 state, suggesting that the quenched state corresponds to almost $\gamma_{HS}$ = 1. The $T_{TIESST}$ (Thermally Induced Excited Spin State Trapping) value is estimated at 61 K, and the HS-2-to-LS relaxation at this temperature is as abrupt as those for the thermal transitions. These magnetic measurements prove without any ambiguity that it is possible to quench $[Fe(btr)_2(NCS)_2]\cdot H_2O$ single-crystal samples in the HS-2q state.

For the second measurement (Figure 5b), the sample was cooled gradually from room temperature (HS-1 state) to 10 K (LS state) and then irradiated with a laser at $\lambda$ = 514 nm ($P$ = 5 mW $cm^{-2}$) to promote the HS-2p state. The $\chi_M T$ value rose up to 0.63 $cm^3 K mol^{-1}$ after a 15-h continuous irradiation, which indicates partial LS-to-HS-2p photoconversion. By comparison with the $\chi_M T$ value obtained at 160 K for the HS-1 state (3.0 $cm^3 K mol^{-1}$), a photoconversion of about 21% is estimated. On increasing the temperature in the dark, the HS-to-LS relaxation is observed at $T$ = 61 K. Under 60-mW $cm^{-2}$ excitation with green light of 550 nm wavelength at $T$ = 10 K, Morscheidt et al.[25] also induced a partial conversion of at most 20% HS-2.

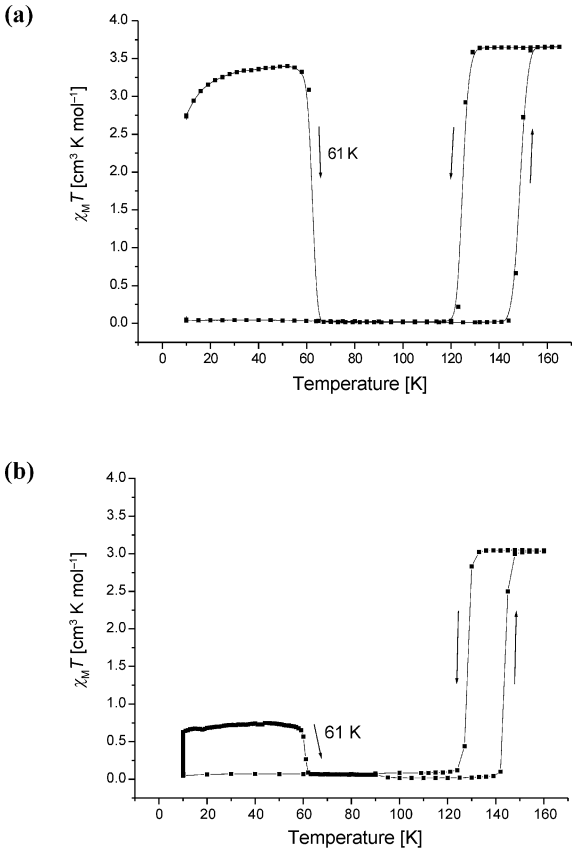

Figure 5. Temperature dependence of $\chi_M T$ for (a) the thermally quenched sample and (b) the photoinduced sample.

Finally, the photoexcitation and relaxation kinetics were derived. The magnetic signal was recorded during a 23-h continuous irradiation at 10 K at $\lambda$ = 514 nm (Figure 6a). It clearly shows a nonlinear sigmoidal behaviour, which has been attributed to a competition between photoexcitation and relaxation by Enachescu et al. for $[Fe_xM_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ derivatives (M = Ni, Co, Zn).[26] This is the basis for the light-induced instability phenomenon. After saturation of the magnetic signal at 0.89 $cm^3 K mol^{-1}$, the excitation light was turned off, and the magnetic signal was monitored in the dark. The negligible change in the signal in the dark, although a slight negative trend is noticeable, confirms the high stability of the HS-2 state at $T$ = 10 K, in the tunnel relaxation regime. The reverse-LIESST effect was then induced by using an excitation wavelength corresponding to the $^5T_2 \rightarrow {}^5E$ transition at $\lambda$ = 830 nm (following the optical reflectivity results); the irradiance was set to 5 mW $cm^{-2}$. The sudden change in the slope and the continuous decrease in the magnetic signal therefore confirm the reversibility of the light-induced LS–HS conversion for $T < T_{LIESST}$. The molar magnetic susceptibility of the HS-2 state at 10 K after thermal trapping was also monitored as a function of time and converted to $\gamma_{HS}$ (Figure 6b) in order to calibrate the 15-K photocrystallographic measurements. The relaxation kinetics is very slow at this temperature, which is well below $T_{LIESST}$ and $T_{TIESST}$, and corresponds to the tunnel relaxation regime.

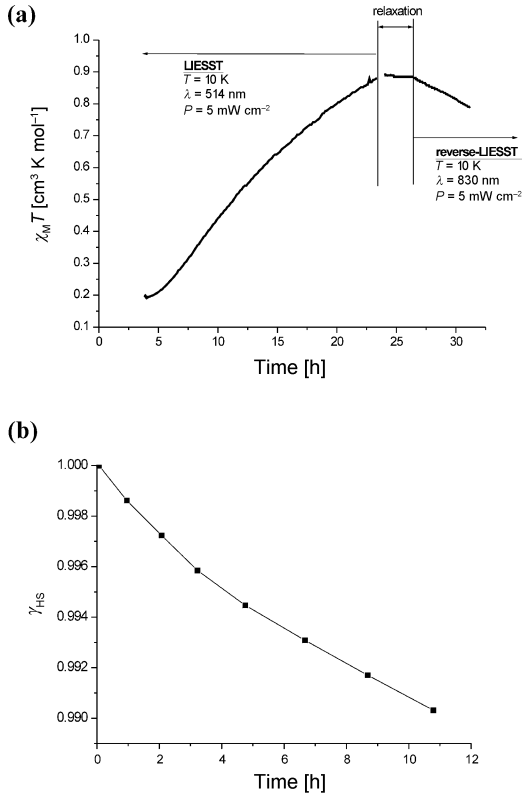

Figure 6. (a) Time dependence of $\chi_M T$ during LS→HS photoexcitation (LIESST) and HS→LS photorelaxation (reverse-LIESST) at 10 K. (b) Relaxation kinetics of the quenched metastable HS state in the dark at 10 K, derived from susceptibility measurements as a function of time.

All together, these magnetic results, in addition to the previous optical properties, are mandatory for the choice of appropriate experimental conditions for the photocrystallographic measurements (temperature, excitation wavelength and duration). They indeed confirm the possibility for a careful X-ray diffraction measurement on the HS-2q and HS-2p states at very low temperature ($T \approx 10$ K), as the necessary requirements are met: possible photoconversion, efficient thermal quenching, high relaxation $T_{LIESST}$ and $T_{TIESST}$ temperatures and an almost negligible relaxation rate at sufficiently low temperature (10 K).

## Thermal Expansion Analysis

The lattice constants of $[Fe(btr)_2(NCS)_2]\cdot H_2O$ were derived from single-crystal X-ray diffraction as a function of temperature (15 K $< T <$ 270 K) in all the different spin states and are reported in Figure 7. From room temperature to 124 K, in the HS-1 state, the *a* and *b* cell axes contract linearly, whereas the *c* axis slightly expands in a linear fashion, leading to a thermal contraction of the unit cell volume. Upon passing the thermal spin transition at $T_{1/2\downarrow}$ = 124 K, the lattice constants change abruptly, giving a cell volume variation, $\Delta V_{HL}$, of –91 Å$^3$ (5%). In the LS state (15 K $< T <$ 144 K), a contraction of the *a* and *b* axes and an expansion of the *c* axis are observed. Remarkably, the lattice parameters in the metastable HS-2 states are in almost perfect linear continuity to those of the HS-1 state. At 15 K, the cell volume expansion from LS to HS-2, $\Delta V_{HL}$ = +91 Å$^3$, exactly matches the volume variation at the thermal transition.

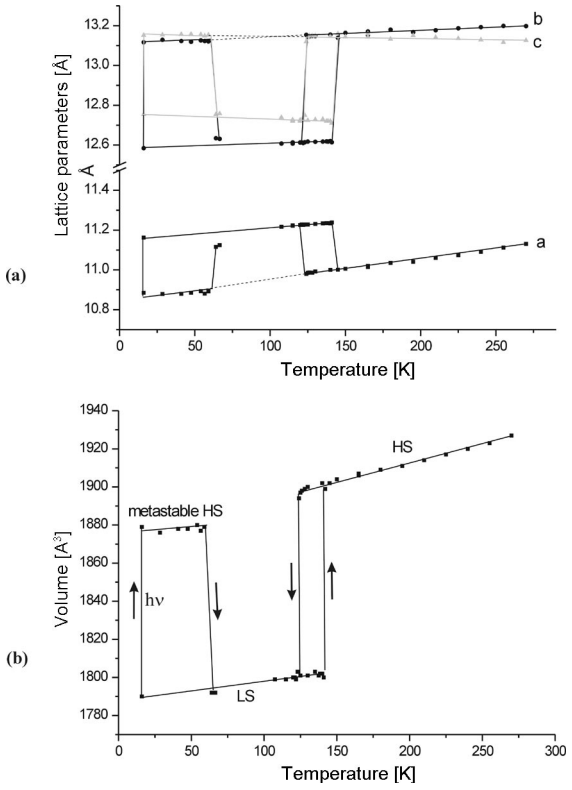

Figure 7. (a) Unit cell parameters and (b) unit cell volume as a function of temperature (15–270 K).

The temperature dependence of the lattice constants was further analyzed by using the formalism of the lattice expansion model.[27] This model, which is based on the assumption of a direct proportionality between the HS–LS cell volume change and $\gamma_{HS}$, was efficiently used to describe the behaviour of several spin-crossover materials such as $[Fe(mtz)_6]\cdot(BF_4)_2$ and $[Fe(ptz)_6]\cdot(BF_4)_2$.[28,29] In the generalized form of this model, a vector, $\mathbf{X}(T)$, is given by Equation (1):

$$\mathbf{X}(T) = \{\mathbf{1} + \boldsymbol{\alpha} T + \boldsymbol{\varepsilon}\gamma_{HS}(T)\}\mathbf{X}\,(T = 0) \quad (1)$$

In Equation (1), $\boldsymbol{\alpha}$ is related to the thermal expansion of the crystal lattice, whereas $\boldsymbol{\varepsilon}$ describes the spontaneous strain (deformation) of the crystal lattice upon LS–HS transition. The thermal expansion of a crystal lattice is well described by the Grüneisen approximation, including anharmonicity contributions. The free energy of the crystal lattice is parameterized by its bulk modulus, the vibration energy of the phonons and the Grüneisen constant.[30] In a first approximation, $\boldsymbol{\alpha}$ is assumed to be the same in the HS and LS states, which is usually quantitatively sufficient for spin-crossover materials whose crystal structure consists of individual molecular entities.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

The lattice parameters were fitted by the least-squares method to linear functions, whose coefficients exhibit significant spin dependencies (Table 1). Accordingly, we anticipate that the assumption that the thermal-expansion tensor, $\boldsymbol{\alpha}$, is the same for both spin states is hardly fulfilled in the case of $[Fe(btr)_2(NCS)_2]\cdot H_2O$, because of its particular 2D polymeric crystal structure. Indeed, different phonon vibration energies might be expected on changing from the LS to the HS state. In such a case, a more general expression of the lattice expansion model given by Equation (1), including spin-dependent thermal-expansion tensors $\boldsymbol{\alpha}_{HS}$ and $\boldsymbol{\alpha}_{LS}$, is required [Equation (2)]:

$$\mathbf{X}(T) = \left[\mathbf{1} + \left\{\gamma_{HS}(T)\boldsymbol{\alpha}_{HS} + [1-\gamma_{HS}(T)]\boldsymbol{\alpha}_{LS}\right\}T + \boldsymbol{\varepsilon}\gamma_{HS}(T)\right]\mathbf{X}(T=0) \quad (2)$$

Table 1. Results of the least-squares fit of the lattice parameters as a function of temperature using linear functions $\mathbf{X}(T) = \mathbf{X}(0) + \boldsymbol{\alpha}_L T$.

| Parameter | Spin state | Fitted functions |
|---|---|---|
| $a$ | HS | $10.857(3) + 9.9(2)\times10^{-4}\,T$ |
| | LS | $11.157(1) + 5.7(1)\times10^{-4}\,T$ |
| $b$ | HS | $13.106(4) + 3.4(3)\times10^{-4}\,T$ |
| | LS | $12.581(2) + 2.6(2)\times10^{-4}\,T$ |
| $c$ | HS | $13.153(5) - 7(3)\times10^{-5}\,T$ |
| | LS | $12.76(1) - 2.6(7)\times10^{-4}\,T$ |
| $\beta$ | HS | $90.74(4) + 3.5(36)\times10^{-3}\,T$ |
| | LS | 92.37(3) |

By using $\gamma_{HS}(T)$ derived from the magnetic measurements, the elements of the tensors $\boldsymbol{\alpha}_{HS}$, $\boldsymbol{\alpha}_{LS}$ and $\boldsymbol{\varepsilon}$ in Equation (2) were fitted to the measured values of the lattice parameters vs. temperature through a Monte Carlo algorithm, until the minimum of the agreement function $R = \Sigma[x_{obs}(T) - x_{calc}(T)]^2/\Sigma[x_{obs}(T)]^2$ was reached. Results of the fit are given in Table 2. The orthonormal coordinate system attached to the crystal was defined as conventional in the monoclinic system: $\boldsymbol{e_2}//b$, $\boldsymbol{e_3}//c$ and $\boldsymbol{e_1}//a^*$.

The elements of the $\boldsymbol{\alpha}_{HS}$ and $\boldsymbol{\alpha}_{LS}$ tensors clearly indicate a similar behaviour with nonetheless some specific discrepancies. In both spin states, the largest eigenvalue corresponds to an eigendirection almost along the crystallographic $a$ axis, that is to say perpendicular to the structural layers, as can be seen in Figure 8. The coefficients $a^0_{22}$ and $a^0_{33}$ correspond to two mutually perpendicular directions roughly parallel to the structural layers. The interlayer region is therefore the most affected by temperature ($a^0_{11} > a^0_{22}$, $a^0_{33}$); the corresponding thermal contraction is furthermore almost twice as large in the HS state [$a^0_{11} = 9.73(7)\times10^{-5}\,K^{-1}$] as that in the LS state [$a^0_{11} = 5.05(3)\times10^{-5}\,K^{-1}$]. Correlatively, the overall thermal volume contraction, approximated by the trace of the $\boldsymbol{\alpha}$ tensor [$Tr(\boldsymbol{\alpha}) = a^0_{11} + a^0_{22} + a^0_{33}$], is also twice as large in the HS state. This behaviour correlates to a slight reduction of the hydrogen-bond strength, which is responsible for the interlayer connection, in the HS state with an increase in the Ow···N12 distances [$d_{Ow\cdots N12}$(LS) = 3.026(3) Å and $d_{Ow\cdots N12}$(HS) = 3.065(1) Å at 130 K for instance]. In both spin states, the thermal volume contraction is much lower than that observed for molecular spin-crossover systems {$Tr(\boldsymbol{\alpha}) = 26\times10^{-5}\,K^{-1}$ at 298 K in the HS state for [Fe(PM-BiA)$_2$(NCS)$_2$] for instance},[11] due to the lower sensitivity to deformation of the crystal lattice of $[Fe(btr)_2(NCS)_2]\cdot H_2O$. This is expected on the basis of its polymeric crystal structure.

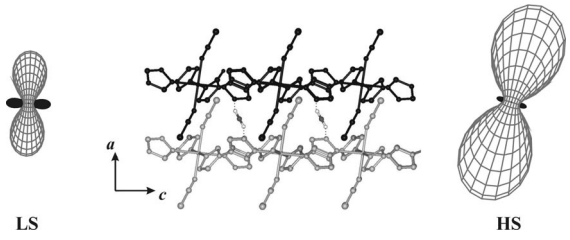

Figure 8. Representation of the thermal-expansion tensor in the HS and LS states oriented with respect to the layer crystal structure. Positive thermal expansion is displayed in light grey, negative in black.

Table 2. Coefficients $a_{ij}$ and eigenvalues $a^0_{ij}$ of the thermal-expansion tensors ($\boldsymbol{\alpha}_{LS}$, $\boldsymbol{\alpha}_{HS}$) and coefficients $\varepsilon_{ij}$ and eigenvalues $\varepsilon^0_{ij}$ of the spontaneous-strain tensor ($\boldsymbol{\varepsilon}$).

| | $a_{11}$ [$10^{-5}$ K$^{-1}$] | $a_{22}$ [$10^{-5}$ K$^{-1}$] | $a_{33}$ [$10^{-5}$ K$^{-1}$] | $a_{13}$ [$10^{-5}$ K$^{-1}$] |
|---|---|---|---|---|
| $\boldsymbol{\alpha}_{HS}$ | 8.86(7) | 2.62(1) | –0.58(1) | –3.00(8) |
| $\boldsymbol{\alpha}_{LS}$ | 5.05(3) | 2.08(1) | –2.08(2) | –0.043(1) |
| | $a^0_{11}$ [$10^{-5}$ K$^{-1}$] | $a^0_{22}$ [$10^{-5}$ K$^{-1}$] | $a^0_{33}$ [$10^{-5}$ K$^{-1}$] | $Tr(\boldsymbol{\alpha})$ [$10^{-5}$ K$^{-1}$] |
| $\boldsymbol{\alpha}^0_{HS}$ | 9.73(7) | 2.62(1) | –1.43(1) | 10.92(9) |
| $\boldsymbol{\alpha}^0_{LS}$ | 5.05(3) | 2.08(1) | –2.08(2) | 5.05(6) |
| | $\varepsilon_{11}$ [$10^{-2}$] | $\varepsilon_{22}$ [$10^{-2}$] | $\varepsilon_{33}$ [$10^{-2}$] | $\varepsilon_{13}$ [$10^{-2}$] |
| $\boldsymbol{\varepsilon}$ | –2.62(1) | 4.17(1) | 3.11(1) | 1.46(1) |
| | $\varepsilon^0_{11}$ [$10^{-2}$] | $\varepsilon^0_{22}$ [$10^{-2}$] | $\varepsilon^0_{33}$ [$10^{-2}$] | $Tr(\boldsymbol{\varepsilon})$ [$10^{-2}$] |
| $\boldsymbol{\varepsilon}^0$ | –2.97(1) | 4.17(1) | 3.46(1) | 4.66(3) |

The spontaneous strain at the HS–LS transition is also highly anisotropic, with a negative contribution along the crystallographic $a$ axis and positive values along the $b$ and $c$ axes. The HS–LS transition correlates therefore to an increase in the interlayer spacing and an overall contraction parallel to the layers. The former aspect is related to a reorientation of the NCS group with a more linear Fe–N–C–S geometry in the LS state (see below), whereas the contraction within the layer is connected to the abrupt Fe–N bond shortening at the transition. Note that $\boldsymbol{\varepsilon}$ was fitted on the whole temperature range, and it therefore assumes an identical spontaneous strain at the thermal and light-induced transitions.

### Similarities between the HS-2q and HS-2p Structures

The lattice parameters exhibit systematic positive differences from HS-2p to HS-2q: $\Delta a$ = 0.031(2) Å, $\Delta b$ = 0.049(2) Å, $\Delta c$ = 0.015(2) Å [$\Delta V$ = 14.4(5) Å$^3$]. This positive

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

volume discrepancy would suggest that HS-2p corresponds to an incomplete metastable HS-2 state with some residual LS species. The comparative structural characteristics of the $FeN_6$ octahedron are given in Table 3. On the whole, the mean-square atomic position deviation, *mfa*, is only 0.0125 Å between these two metastable HS-2 crystal structures, as calculated by mapping the structures of the $Fe(btr)_4(NCS)_2$ fragment with KPLOT,[31] including only non-hydrogen atoms. It is worth noting that the bond lengths are systematically more precise and larger in the HS-2q state than in HS-2p, but the differences for the Fe–N bonds are within $2\sigma$. The angular deformation of the $FeN_6$ octahedron, defined as the sum of the deviations from 90° of the 12 *cis* N–Fe–N angles in the coordination sphere,[2] shows some differences: $\Sigma_{HS\text{-}2q}$ = 15.6(4)° and $\Sigma_{HS\text{-}2p}$ = 18(2)°. The differences between HS-2p to HS-2q in the btr bond lengths and angles are in the range of the experimental uncertainty, except for the N14–N24, N22–C23 and N21–C25 bonds which are at the limit of the statistical significance. The geometry of the NCS ligand is also very similar, with bond lengths, *d*(N–C), of 1.179(1) and 1.174(8) Å and *d*(C–S) values of 1.634(1) and 1.631(6) Å for the HS-2q and HS-2p states, respectively. The interlayer Ow–Hw···N12 hydrogen-bond contacts present the same structural characteristics, with Ow···N12 distances of 3.044(2) and 3.036(7) Å for the HS-2q and HS-2p states, respectively, correlated to a slight displacement of the water molecule [$\Delta d$(Ow) = 0.009(3) Å].

Table 3. Selected structural characteristics in the various spin states. The octahedron volume $V_p$ was calculated with IVTON.[44]

| | 15 K | | | 130 K | |
|---|---|---|---|---|---|

| Fe–N–C | 162.79(4) | 149.46(8) | 149.0(5) | 163.1(1) | 150.66(6) |
| Σ [°] | 14.8(2) | 15.6(4) | 18(2) | 14.4(7) | 15.4(3) |
| $V_p$ [Å$^3$] | 10.09(1) | 13.34(1) | 13.2(1) | 10.10(1) | 13.41(1) |

According to the structural arguments presented here, we cannot firmly confirm or reject the hypothesis that HS-2q and HS-2p correspond to a unique phase in the case of $[Fe(btr)_2(NCS)_2]\cdot H_2O$.

### LS→HS-2q Structural Modifications at 15 K

Figure 9 presents a superposition of the molecular structures in the LS and HS-2q states at 15 K. The mean-square atomic position deviation,[31] *mfa*, which in this case gives insight into the mean magnitude of the LS-to-HS-2q atomic displacement, is 0.272 Å (Table 4). This value is very similar for the LS-to-HS-2p transition (*mfa* = 0.270 Å). Upon the LS-to-HS-2q spin-state change, the Fe–N coordination bonds expand by $\Delta d$(Fe–$N_{NCS}$) = 0.181(2) Å, $\Delta d$(Fe–N11) = 0.198(2) Å and $\Delta d$(Fe–N21) = 0.196(2) Å. The deformation of the $FeN_6$ octahedron is slightly lower in the LS state [$\Sigma_{LS}$ = 14.8(2)°] than in the HS-2q phase [$\Sigma_{HS\text{-}2q}$ = 15.6(4)°], which is the usual trend for such iron(II) compounds. However, these deformations are much less severe than those for other $Fe(L)_2(NCS)_2$ spin-transition complexes whose $\Sigma_{HS}$ values are typically around 70°.[2] The $FeN_6$ octahedron volume changes by $\Delta V_p$ = +3.25(2) Å$^3$, which accounts for only 14% of the total unit cell volume variation ($\Delta V_{cell}$ = +92 Å$^3$), since there are four iron octahedrons per unit cell. During the spin-state change, the NCS ligand, in the *trans* position, undergoes a reorientation by $\Delta\theta_{LH}$ = –13.3(1)°, the Fe–N–C angle being closer to 180° in the LS state than in the HS-2q state. As discussed above, this NCS reorientation is correlated to the expansion of the crystallographic *a* axis, which increases the interlayer spacing, and therefore is the main contribution to $\Delta V_{cell}$. As for the btr ligand, the variations in bond length and angle are

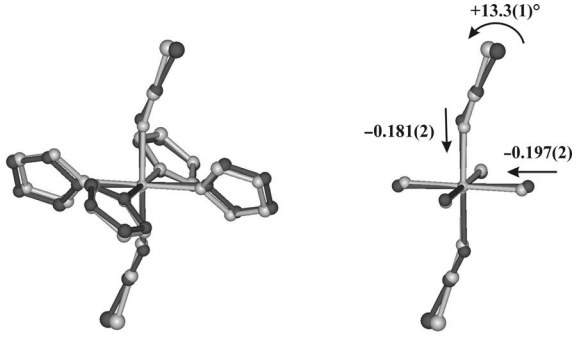

Figure 9. Superposition of the molecular structures in the LS state (grey) and the HS-2q state (black) at 15 K.

Table 4. Geometrical reorganization of the $FeN_6$ octahedron upon various spin-state changes. *mfa* is the mean-square atomic position deviation, given by $mfa = (\sum_{i=1}^{n} S_i^2/n)^{1/2}$, where the $S_i$ are the distances [Å] between corresponding pairs of atoms in the two structures. *mfa* was calculated by using KPLOT.[31]

| Bond length [Å] | LS→HS-2p (15 K) | LS→HS-2q (15 K) | LS→HS-1 (130 K) |
|---|---|---|---|
| Fe–N | +0.179(5) | +0.181(2) | +0.179(2) |
| Fe–N11 | +0.193(7) | +0.198(2) | +0.202(2) |
| Fe–N21 | +0.185(6) | +0.196(2) | +0.203(2) |
| N–C–S | –0.01(1) | –0.002(3) | –0.011(6) |
| Ow···N12 | +0.011(8) | +0.019(3) | +0.039(4) |
| Angle [°] | | | |
| N–Fe–N11 | +0.7(2) | +0.54(6) | +0.60(9) |
| N–Fe–N21 | 0.0(2) | +0.02(5) | +0.04(8) |
| N11–Fe–N21 | –0.2(2) | –0.34(6) | –0.39(8) |
| Fe–N–C | –13.8(5) | –13.3(1) | –12.5(2) |
| ΔΣ [°] | +3(2) | +0.8(6) | +1(1) |
| $\Delta V_p$ [Å$^3$] | +3.1(1) | +3.25(2) | +3.31(2) |

within the experimental uncertainty, whereas the dihedral angle between the triazole rings increases significantly from 84.81(3)° to 88.20(6)°. Finally, we note a displacement of the water molecule along the crystallographic *b* direction [$\Delta d(\mathrm{Ow})_{\mathrm{HL}}$ = –0.236(1) Å] resulting in a small increase in the interlayer Ow···N12 contacts by 0.019(3) Å.

### LS→HS-1 Structural Reorganization at 130 K

Upon the LS-to-HS-1 spin-state change at 130 K, the mean-square atomic position deviation is 0.266 Å, which is marginally lower than that calculated for the LS-to-HS-2q transition. As a matter of fact, the 130 K HS and 15 K HS-2q states are closely related to each other (*mfa* = 0.0317 Å); this criterion is even lower for the corresponding LS structures (*mfa* = 0.0155 Å). The coordination bonds expand by $\Delta d(\mathrm{Fe–N_{NCS}})$ = 0.179(2) Å, $\Delta d$(Fe–N11) = 0.202(2) Å and $\Delta d$(Fe–N21) = 0.203(2) Å, which are within the $\sigma$ values calculated for the LS-to-HS-2q spin-state change. As for the latter, the angular distortion of the $FeN_6$ octahedron is smaller in the LS state [$\Sigma_{\mathrm{LS}}$ = 14.4(7)°] than in the HS-1 one [$\Sigma_{\mathrm{HS\text{-}1}}$ = 15.4(3)°]. The $FeN_6$ octahedron volume changes by $\Delta V_{\mathrm{p}}$ = +3.31(2) Å$^3$, which accounts for nearly 13% of the unit cell volume change ($\Delta V_{\mathrm{cell}}$ = 99 Å$^3$), similar to the LS-to-HS-2q spin-state change. The bond length variations of the btr ligand between the two spin states are within the uncertainty, except for the bonds C13–N14 and C23–N24, which are slightly longer in the LS state. The dihedral angle between the triazole ring planes has the same values as at 15 K [84.8(1)° and 88.32(4)° in the LS and HS-1 states, respectively]. Again, as for the LS-to-HS-2q transition at 15 K, we observe a reorientation of the NCS by $\Delta\theta_{\mathrm{LH}}$ = –12.5(2)°. Finally, we note a 0.039(4)-Å increase in the intermolecular Ow···N12 contact in the HS-1 state with respect to the LS state. The displacement of the water molecules along the crystallographic *b* direction is in this case $\Delta d(\mathrm{Ow})_{\mathrm{HL}}$ = –0.255(1) Å. As a conclusion, we can claim that the LS→HS-2q and LS→HS-1 transitions lead to almost identical structural modifications.

### Thermal Motion Analysis

The importance of molecular vibrations in the spin conversion phenomenon was first recognized by Sorai and Seki on the basis of calorimetric measurements; they indeed revealed that the spin transition is an entropy-driven process.[32] If we look in general at spin-crossover materials, $\Delta S_{\mathrm{LH}}$ typically amounts to about 50 J K$^{-1}$ mol$^{-1}$, of which the vibrational contribution to the molar entropy accounts merely for 60–70%, while the electronic (spin multiplicity) entropy represents only 13.4 J K$^{-1}$ mol$^{-1}$ in the case of $Fe^{II}$ spin-crossover complexes. It is generally assumed that the major contributions to the vibrational entropy results from the 15 intramolecular normal modes of the regular $FeN_6$ octahedron and predominantly from the Fe–N stretching modes. Detailed IR and Raman spectroscopic measurements as well as nuclear inelastic scattering results, coupled to ab initio DFT calculations on isolated molecules, indicate, on the other hand, that some external (phonon) modes might also contribute significantly to the vibrational entropy.[33] However, a comprehensive knowledge of the importance of these phonon modes is still missing. Several models for spin crossover account explicitly for the role of vibrations, through a reduced number of empirical parameters such as the HS and LS Debye temperatures [$\Theta_{\mathrm{D}}$(HS) and $\Theta_{\mathrm{D}}$(LS), Zimmerman and König model[34]] or the effective HS and LS degeneracies of electro-vibrational origin ($\omega_{\mathrm{HS}}$ and $\omega_{\mathrm{LS}}$ in the two-level Ising-like model introduced by Bousseksou et al.[35]).

Literature results indicate that for the title $[Fe(btr)_2(NCS)_2]\cdot H_2O$ complex, $\Delta S_{\mathrm{LH}}$ is as high as 76 J K$^{-1}$ mol$^{-1}$.[21a] On the basis of its specific extended layer structure, the large cell volume change and the structural modifications at the spin transitions, large modifications of the atomic vibration amplitudes are expected as well. For cyanide-bridged iron(II) spin-crossover complexes, which exhibit a polymeric crystal structure, it has been suggested from Raman measurements that the contribution from intermolecular vibration to the total entropy might be non-negligible.[36] This is most probably related to the strong cooperativity induced by the extended polymeric structure. For similar reasons, lattice vibrational modes might also play an important role in $[Fe(btr)_2(NCS)_2]\cdot H_2O$. We have derived here the crystal structure in both spin states at two temperatures (15 K and 130 K), which affords the possibility to characterize the difference in vibrational behaviour (vibration modes and amplitudes) between HS and LS. The atomic vibration amplitudes, described through the atomic $\mathbf{U}_{ij}$ tensor in a conventional structural analysis (like the one performed here), consist of additive contributions from intramolecular vibration modes of high frequency and lattice vibrations (phonons) of lower frequency. For the thermal transition, the atomic displacement tensors were derived from the present structural analysis, whereas for the 15 K case, the atomic displacement tensors (for LS and HS-2q) were derived from the more accurate multipolar model of the electron density previously published.[16] In the latter, thermal vibrations are decorrelated from aspherical electron-density features. Recent experimental and theoretical investigations include the intramolecular normal modes of the regular $FeN_6$ octahedron as well as the ligand vibration modes through a multicoordinate approach.[33] We will rather follow here a simpler single-coordinate procedure.

Upon LS-to-HS state change (LS→HS-1 and LS→HS-2), a systematic enhancement in equivalent isotropic displacement parameters is observed, as shown in Table 5 and illustrated in Figure 10. The most striking feature is a similar trend from atom to atom at the two temperatures, the increase being nevertheless higher in almost all cases at 130 K. In the case of sulfur, the increase is much larger at 130 K than for all the other atoms and seems suspicious; it is most probably related to some disordering effects, which can not be resolved in the crystal structure analysis but are taken into account in the corresponding atomic displacement parameters. The systematic LS-to-HS increase in

atomic displacement amplitudes can be directly related to the spin transition and indicates vibration modes of globally larger amplitudes in the HS state; it can not be attributed to a population of higher-energy vibrational levels since measurements have been performed at rigorously the same temperature. This behaviour can be pictured by a mean potential well that is globally broader in the HS state (inset in Figure 10).

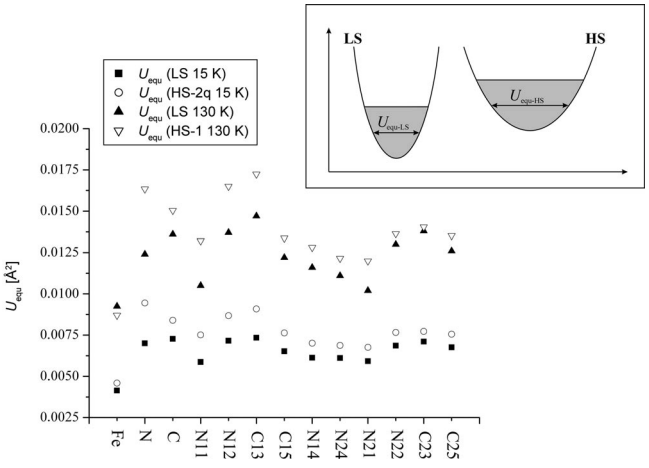

Figure 10. Equivalent isotropic displacement parameters $U_{equ}$ [$U_{equ}$ = 1/3($U_{11}$ + $U_{22}$ + $U_{33}$)]. The S atom has been omitted as it is possibly affected by some disordering effects (see text). Inset: schematic representation of the mean HS and LS vibrational potential wells.

The inspection of the anisotropic displacement parameters allows us to proceed further. Figure 11 displays the difference mean-square surfaces [$U_{HS}$ – $U_{LS}$] at 15 K and 130 K; it is evident that similar features are present at both temperatures. First of all, the atomic displacement amplitudes are systematically higher in the HS state with respect to the LS state, as discussed above. In the case of sulfur, the thermal motion is higher in the direction perpendicular to the NCS axis in the HS state, therefore characterizing a higher bending vibration of the NCS group together with a possible static disorder of the sulfur atom. The difference for btr also exhibits a systematic trend, the thermal motion being higher in the direction perpendicular to each triazole ring for all atoms. The fact that all btr atoms behave collectively confirms that this behaviour is due to higher vibration amplitudes of external (lattice) modes in the HS state and is indeed related to the spin-state change.

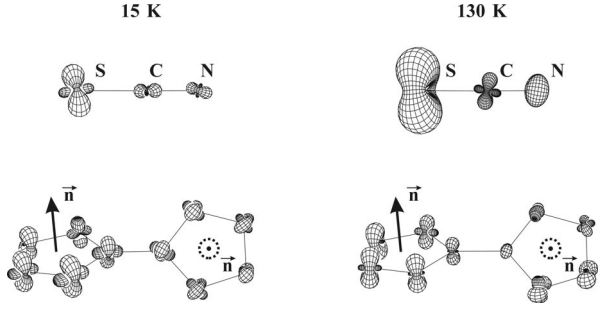

Figure 11. Difference mean-square surfaces [$U_{HS}$ – $U_{LS}$] calculated by using PEANUT.[43] Positive surfaces are in grey, negative surfaces are in black. The arrows depict the normal to each triazole ring.

Let us consider that the vibrational properties of each molecular fragment (btr, NCS and Fe) in each spin state can be described by a mean single harmonic oscillator (rigid group model). This is a gross approximation which can, however, help rationalize the observed trends. The mean-square displacement amplitude corresponding to a harmonic oscillator is related to the vibration frequency by $\langle u^2 \rangle = \frac{h}{8\pi^2 \mu \nu} \coth(h\nu/2k_B T)$, where $\mu$ is the reduced mass and $\nu$ the oscillator frequency. $\langle u^2 \rangle$ is a decreasing function of the oscillator frequency, $\nu$. In this context, at constant temperature, the increase in the mean-square displacement amplitude in the HS state is related to a decrease in oscillator frequency and correlatively to a decrease in the stiffness of the crystal lattice; thus $\nu_{HS} < \nu_{LS}$. For this hypothetical harmonic oscillator, the vibrational entropy is a decreasing function of the oscillator frequency; thus $S_{HS} > S_{LS}$. We therefore predict, as a result of our structural analysis an increase in vibrational entropy upon LS-to-HS state change due to the external vibration modes. This positive contri-

bution to $\Delta S_{LH}$ from external modes could explain the remarkably high LS-to-HS total entropy change for $[Fe(btr)_2(NCS)_2]\cdot H_2O$.

All together, these results show the relevance of such a structural analysis by using high-resolution X-ray diffraction for getting new insights into the vibrational properties of spin-crossover materials.

## Conclusions

This paper describes the structural properties of the LS and HS states of the spin-crossover complex $[Fe(btr)_2(NCS)_2]\cdot H_2O$ and their modifications during the thermal (130 K) and the LIESST (15 K) spin transitions. The LIESST process at very low temperature and the metastable HS-2-to-LS relaxation have been described on the basis of spectroscopic and photomagnetic measurements. The very slow relaxation of the photostationary HS-2 state allows precise crystallographic studies of the metastable HS-2p and HS-2q states.

The X-ray diffraction measurements of the LS and HS states at rigorously the same temperature for the two conversions allow a precise description of the structural variations attributed to the spin transition, free from any disturbing thermal effect. Under these considerations, we showed that both HS-2 states obtained by thermal quenching from room temperature and by photoirradiation have the same molecular structures, within experimental limits of accuracy (less than 0.01 Å). In addition, our results suggest that the LIESST and the thermal spin transitions lead to the same structural variations of the iron coordination polyhedron: the Fe–N bond lengths extend by 0.18 and 0.20 Å on going from LS to HS, and the NCS group undergoes a reorientation of nearly 13°, which accounts for the extension of the crystallographic *a* axis. The HS→LS transition reduces the intermolecular Ow–Hw···N12 contacts in the crystallographic *a* direction.

We have shown in the present analysis that detailed vibrational properties related to the spin transition can be derived from X-ray diffraction measurements, providing high-resolution (in Q) data are measured. Systematically higher vibration amplitudes are observed in the HS state as compared to the LS state. For the btr group, the collective increase in vibration amplitude is perpendicular to each triazole ring and results from globally lower-frequency external vibration modes in the HS state. These might contribute significantly to $\Delta S_{HL}$.

The thermal-expansion tensors for the HS and LS states exhibit a similar qualitative behaviour that parallels the specific layer crystal structure. In both spin states, the largest value of the thermal-expansion tensor is observed along the crystallographic *a* direction, that is, perpendicular to the structural layers. The corresponding thermal contraction is twice in the HS state with respect to the LS state. On the other side, the contraction is lower in the directions parallel to the layers. The spin transition in $[Fe(btr)_2(NCS)_2]\cdot H_2O$ is associated to large and anisotropic spontaneous strain, characterized by the tensor **ε**, whose eigenvalues correlate to an abrupt increase in the interlayer spacing and an overall contraction parallel to the layers.

## Experimental Section

**Sample Preparation:** The btr ligand and its iron complex, $[Fe(btr)_2(NCS)_2]\cdot H_2O$, were synthesized as reported in the literature.[37] Single crystals, suitable for accurate crystallographic studies, were grown by slow solvent evaporation in aqueous solution. For consistency, single crystals of similar quality and size were used for all the experiments: single-crystal X-ray diffraction, optical and magnetic measurements.

**Estimation of Crystal Heating during Photoexcitation:** We report in this paper the physical properties of the light-induced metastable state of $[Fe(btr)_2(NCS)_2]\cdot H_2O$ obtained by using various laser excitation conditions (laser wavelength and power) for the photomagnetic, reflectivity and photocrystallographic measurements. It is of fundamental importance to address the question of crystal heating under such laser excitation. Whatever the experiment, it is commonly assumed and hoped that this sample heating is reduced, but no clear procedure has ever been proposed for estimating the temperature increase in the probed sample. We propose here a very simple empirical procedure for the case of photocrystallographic experiments.

Prior to any photocrystallographic measurement, it is of common practice to analyze comparatively the UV/Vis absorption spectra of the ground and light-induced excited states from which the excitation conditions (laser wavelength and power) are optimized. In the case of spin-crossover materials, excitation wavelength corresponding to the spin-allowed $^1A_1$ to $^1T_1$ or MLCT (Metal-to-Ligand Charge Transfer) absorption band is commonly chosen. Under such excitation conditions, the energy transferred to the sample partly induces the LS-to-HS excitation, but is also dissipated by emission of phonons. This latter process may raise the sample temperature by several tens of degrees, which could drastically damage it or cause false interpretations of the LIESST phenomenon. By using typical heat conduction properties (thermal conductivity) of molecular crystals, characteristics (stream diameter and velocity) and heat convection properties of the cooling $N_2$ or He gas stream (density, heat capacity, kinematic viscosity,...), and laser excitation parameters (penetration depth, linear absorption coefficient, laser power), the heat-transfer equations could be solved numerically, but not without difficulty, to attain the temperature increase profile in a single-crystal sample.[38] We propose here a simpler in situ empirical procedure for roughly estimating the maximum sample temperature increase induced by combined photoillumination and open-flow ($N_2$ or He) cooling systems, which is applicable to spin-crossover materials. We use the fact that on increasing temperature and passing through the LS-to-HS-1 spin transition (at $T = T_{1/2\uparrow}$), the cell parameters change significantly. We can therefore first record diffraction frames in the LS state as references. Then turn on the laser and measure the same diffraction frames as a function of laser power. Upon the LS-to-HS transition, a Bragg peak displacement is expected and usually observed. Therefore, a direct inspection of the diffraction pattern while increasing the laser power would indicate the point at which the laser heats the sample to a temperature which is above $T_{1/2\uparrow}$.

This procedure was applied to $[Fe(btr)_2(NCS)_2]\cdot H_2O$. First we performed diffraction measurements on a single crystal of typical size ($0.25 \times 0.20 \times 0.20$ mm) in the LS state below $T_{1/2\uparrow} = 143$ K. At

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

$T$ = 113 K, the crystal was irradiated for 5 min at the optimum wavelength, $\lambda$ = 488 nm, at a laser output power from 0 to 530 mW, and the diffraction pattern before and after excitation was compared. The laser power was calibrated beforehand by using a power-meter. For low laser power (below 530 mW), no changes appeared in the diffraction pattern, whereas at a laser power of 530 mW, a Bragg peak splitting was noticeable, which is indicative of partial LS-to-HS conversion (Figure 12). In other words, part of the crystal sample, most probably the fraction of the crystal just facing the laser, is at a temperature greater than $T_{1/2\uparrow}$, and the temperature increase is at least 32 K. If the laser excitation is stopped, the diffraction pattern returns quickly back to the corresponding LS state, consistent with the measurement temperature, $T$ = 113 K, below $T_{1/2\downarrow}$. This proves that the crystal was not damaged by the laser, even at 530 mW.

It is well known that the specific heat is temperature-dependent, and the light-induced temperature may therefore be different at very low temperature ($T$ = 15 K), at which the LS-to-HS-2p transition is induced in the present work. To check whether this was indeed the case, we performed another diffraction measurement with a starting temperature of 66 K in the LS state, just above $T_{LIESST}$. Again, the laser power was increased while measuring the diffraction pattern to check whether the LS-to-HS-1 transition could be reached. This would indicate a temperature increase of 77 K. Even with the highest laser power of 530 mW, no change was noticeable, which indicated that the temperature increase was indeed limited to below 77 K. Another similar procedure, although not carried out here, would be to prepare the system in the metastable HS-2 (HS-2p or HS-2q) state at very low temperature and inspect the diffraction pattern while increasing the laser power until the HS-2-to-LS LIESST relaxation is observed.

Under such circumstances, we are confident that during our light-induced LS-to-HS-2p experiment at $T$ = 15 K, we did not heat our sample too much to surpass $T_{1/2\uparrow}$ and then quench our sample in the HS-2q state while turning off the laser. We propose that this procedure can be systematically checked prior to any photocrystallographic measurement. It is, however, purely empirical and does not allow a quantitative comparison with other experiments, since it is highly dependent on the current experimental excitation conditions used for the diffraction measurements.

**Spectroscopic and Photomagnetic Measurements:** Optical reflectivity properties were investigated with a custom-built reflectivity setup equipped with a CVI spectrometer, which allows the collection of both the reflectivity spectra within the 450–950 nm range at a given temperature and to follow the temperature dependence of the signal at a selected wavelength (±2.5 nm) at 5–290 K. The analysis was performed on a thin layer of the powdered sample, without any dispersion in a matrix in the cooling mode from room temperature to 10 K and then warming up to 185 K. One has to keep in mind that reflectivity measurements yield surface information as compared to bulk information obtained from photomagnetic and diffraction results.

Magnetic susceptibility measurements were obtained by using an MPMS-55 Quantum Design SQUID magnetometer operating in the 2–340 K temperature range. The temperature was varied at a rate of 0.5 K min$^{-1}$. All magnetic data are plotted as $\chi_M T$ vs. $T$, the molar magnetic susceptibility $\chi_M$ being corrected for the diamagnetism of the closed-shell core and sample diamagnetism. The photomagnetic experiments were carried out by using a Spectra-Physics Kr+ laser (488 nm and 532 nm) or a diode laser (830 nm), with a power of 5 mW cm$^{-2}$ at the sample surface, coupled through an optical fibre to the cavity of the SQUID magnetometer. The $T_{LIESST}$ properties were measured in relation with the previously published method.[7] The sample was first slowly cooled to 10 K in the LS state and then irradiated with the laser. As soon as the photostationary limit was reached (no further increase in the mag-

netic signal), the light irradiation was switched off and the magnetic signal recorded while the temperature was increased at a rate of 0.3 K min$^{-1}$. The $T_{LIESST}$ value is given by the extreme of the curve $\partial\chi_M/\partial T$ vs. $T$. Thermomagnetic data were also collected on the quenched metastable HS state by using a rapid thermal cooling from room temperature directly to 10 K and deriving $T_{TIESST}$ in the same way as $T_{LIESST}$.

**X-ray Diffraction Measurements:** Five data collections were performed in the different spin states: HS-1 and LS at 130 K within the thermal hysteresis loop, LS, HS-2p and HS-2q at 15 K (Figure 1) by using an Oxford Diffraction Xcalibur diffractometer with Mo-$K_\alpha$ radiation and equipped with a CCD Sapphire 2 detector. Diffraction experiments were performed by ω-scans by using a detector-to-sample distance of 50 mm at several detector 2$\theta$ positions. The cooling systems were an Oxford Diffraction He open flow Helijet and a $N_2$ open-flow cryostream. The temperature at the sample position was calibrated by using the tetragonal-to-orthorhombic structural phase transition of $DyVO_4$ at $T$ = 14 K.[39] For the measurements with the $N_2$ open-flow cryostream, the temperature was calibrated with a thermocouple. Owing to the small size of the sample, the temperature gradient inside the crystal can be neglected, the flux being homogeneous and linear at the sample position. All diffraction peaks were integrated by using CRYSALIS software.[40] Cell parameters were derived with a least-squares refinement on all measured reflections. The crystal faces were indexed to perform analytical absorption corrections. The measured reflections were merged and reduced by using SORTAV.[41] There was no evidence for structural phase transition or space group change after all spin-state changes (thermally induced and light-induced transitions). All structures were solved by direct methods and refined on $F^2$ using a similar strategy (SHELXL97).[42] Non-hydrogen atoms were refined anisotropically, hydrogen atoms were located on Fourier synthesis and refined isotropically without any constraint. More specific data collection and refinement details are given below and summarized in Table 6. We should stress the high resolution ($\theta_{max}$) and low internal agreement factor ($R_{int}$) of all the experiments as direct pieces of evidence for the high quality and internal consistency of the measured data.

**Low-Spin-State Data Collection at 15 K**: The single-crystal sample was directly quenched to 70 K (above $T_{LIESST}$); the temperature was gradually decreased further to 15 K. According to the magnetic measurements, the thermal transition of $[Fe(btr)_2(NCS)_2]\cdot H_2O$ is complete; our measured sample corresponds to a purely LS state.

**Metastable High-Spin States. Data Collection and Structural Refinement at 15 K:** The diffraction measurement of the metastable HS-2 states is practically more difficult than that for the LS state, owing to the inherent HS-2-to-LS relaxation. Accordingly, controlled specific conditions had to be found in order to ensure at the same time a complete population of the metastable state and a quenched relaxation. As shown by the magnetic results, the relaxation is almost negligible at 15 K. The change in the unit cell volume in the course of the diffraction measurements could be an appropriate indicator to follow in situ and estimate the HS-2-to-

LS relaxation rate in the course of the diffraction measurements, since the cell volume of the two spin states differ by more than 90 Å$^3$. We have already shown,[16] in the case of the HS-2q state, that the change in the cell volume as a function of time at 15 K exhibits a linear trend with an insignificant negative slope [$V(t)$ = 1880(3) – 0.002(5)$t$]. The metastable state can therefore be considered stationary during the diffraction measurement.

According to our magnetic results, a complete HS-2q state can be trapped at 15 K by flash cooling from room temperature. The HS-2q crystal structure indicates a slight static disorder of the S atom which was refined at two independent positions. The two S positions have complementary refined occupancies of 0.0300(5) and 0.9700(5) for the minor and major positions, respectively. Such a disorder is not uncommon for the axial NCS ligands of spin-transition complexes.

The excitation conditions for the diffraction measurements of the HS-2p state were optimized according to the photomagnetic and spectroscopic results. The absorption band corresponding to the $^1A_1 \rightarrow {}^1T_1$ transition (LIESST effect) is centred at 550 nm. For the photocrystallographic measurements, the optimum conversion was found at $\lambda$ = 488 nm ($P_{laser}$ = 46 mW, exposure time = 30 s), aside the maximum of the absorption band, ensuring a rather good penetration depth in the single-crystal sample. Using these excitation conditions, a complete photoconversion was reached, since at the photostationary state, the Bragg peaks corresponding to the LS state were not noticeable any more. It is to be noted that the data quality of the HS-2p state is lower than that of the HS-2q state, as a result of an increase in crystal mosaicity after light irradiation and, correlatively, a smaller number of collected reflections. It was very difficult to obtain and measure this photoinduced state, and several crystals were destroyed during preliminary irradiation tests. The presently described data set is the best we could achieve. Contrary to the HS-2q crystal structure, we could not detect any S static disorder. Whether this is related to the lower data quality or attributed to a real structural difference between HS-2q and HS-2p is still an open question.

**Low-Spin and High-Spin States. Data Collection and Structural Refinement at 130 K:** We took advantage of the large thermal hysteresis centred at 134 K to measure the HS-1 and LS states at the same temperature, 130 K, in both spin states. This is an important issue since in this case thermal contraction effects do not interfere in the structural comparison. The measured samples were prepared in the appropriate spin state depending on their history. The HS-1 state was obtained directly by cooling from room temperature, whereas for the LS state, the sample was first cooled down to 100 K (below $T_{1/2\downarrow}$ = 123.5 K) and then warmed up to 130 K. Contrary to the HS-2q state, no static disorder was noticed around S in either of the spin states.

CCDC-627392, -627393, -627394, -627395, -627396 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# C–S Bond Activation and Partial Hydrogenation of Thiophene by a Dinuclear Trihydride Platinum Complex

**Ainara Nova,[a] Fernando Novio,[a] Pilar González-Duarte,*[a] Agustí Lledós,*[a] and Rubén Mas-Ballesté[a]**

**Keywords:** C–S activation / Desulfurization / Thiophene / Hydride ligands / Platinum / Reaction mechanisms

[(dppp)$_2$Pt$_2$H$_3$]ClO$_4$ [**I**, dppp = Ph$_2$P(CH$_2$)$_3$PPh$_2$] was found to activate the C–S bond and to cause partial hydrogenation of thiophene. Thus, the reaction of **I** with neat thiophene (**T**) at reflux temperature yields [(dppp)Pt(SC$_4$H$_4$-*C*,*S*)] (**II**) and [(dppp)$_2$Pt$_2$(μ-SC$_4$H$_5$-*C*,*S*)]ClO$_4$ (**III**) at a 2:3 molar ratio. The same reaction in toluene or benzene solvent affords the same complexes **II** and **III** but in a 1:9 molar ratio. The concomitant formation of **II** and **III** was interpreted on the basis of theoretical calculations (DFT), which have provided a detailed insight into the reaction mechanism. Thus, the presence of **T** causes **I** to dissociate into [(dppp)PtH$_2$] and [(dppp)PtH(C$_4$H$_4$S-κ*S*)], this process being a common step for the two ensuing reaction pathways. After dissociation, the activation of the thiophene C–S bond to yield **II** involves participation of [(dppp)PtH$_2$] exclusively. However, the reaction leading to **III** requires the internal migration of the coordinated hydride to the thiophene ligand in [(dppp)PtH(C$_4$H$_4$S-κ*S*)] and the subsequent assistance of the {(dppp)Pt} fragment formed from [(dppp)PtH$_2$] by hydrogen elimination. As a result of the involvement of [(dppp)PtH$_2$] in the formation of both **II** and **III**, the two reaction pathways are competitive. The reactivity of **II** and **III** with various sources of hydride ligands and different protonic acids has also been examined. Thus, the reaction of **II** with HBF$_4$ leads to the thiolate-bridged dinuclear complex [(dppp)$_2$Pt$_2$(μ-SC$_4$H$_5$)$_2$](BF$_4$)$_2$ (**IV**). In the case of **III** the addition of HBF$_4$ leads to [(dppp)$_2$-Pt$_2$(μ-SC$_4$H$_6$)](BF$_4$)$_2$ (**V**), which transforms into **III** by the addition of a base. The X-ray structural characterization of the unprecedented complex **V** is reported here.

## Introduction

The reaction of thiophenes with homogeneous transition metals is considered a good strategy for modeling heterogeneous reactions that occur during the hydrodesulfurization (HDS) of petroleum.[1–6] This is a step in industrial oil refining in which sulfur is removed from crude oil by being chemically converted to $H_2S$ and hydrocarbon products.[7,8] Conventionally, the HDS process involves a reaction with hydrogen gas (up to 200 atm pressure) at temperatures of 300–450 °C over an alumina supported cobalt (or nickel) molybdenum catalyst. The evident importance of HDS together with environmental regulations that dictate increasingly smaller amounts of sulfur in gasoline and gasoil fuels[9,10] account for the current interest in developing more efficient technologies. Several reviews of the results obtained in the search for new heterogeneous catalysts,[11–15] in homogeneous modeling studies with transition-metal complexes[1,2,4,16–18] and in computational studies dealing with several aspects of heterogeneous HDS,[19–23] have already appeared. Remarkably, despite the large number of studies, the mechanism for the heterogeneous HDS of thiophenic molecules is not completely known and current technology has been unsuccessful in treating these compounds to achieve the sulfur levels required by new legislation.

The reactions of thiophenes with soluble metal complexes have provided mechanistic knowledge of the HDS process.[1,5,24–26] Significantly, many metals (Ru, Os, Ir, Re, Pt, Pd) have been shown to be more active as HDS promoters than the molybdenum–cobalt (or nickel) mixtures usually employed in industrial HDS.[10,12–14,27–30] Thus, the reaction of thiophene (**T**) with mono- or dinuclear transition-metal complexes has usually led to the cleavage of a single thiophene C–S bond and thus to the formation of a thiametalacycle as the product[4,31–41] (Scheme 1, right-hand side). Concerning these reactions, the most thorough mechanistic study involves a mononuclear rhodium species.[34] Although no intermediates were detected in this reaction, the use of selectively deuterated reagents and theoretical calculations made it possible to propose the corresponding mechanism.[42–44] In terms of mono- and dinuclear transition-metal complexes, the only example of a complete desulfurization of thiophene to butadiene was achieved by

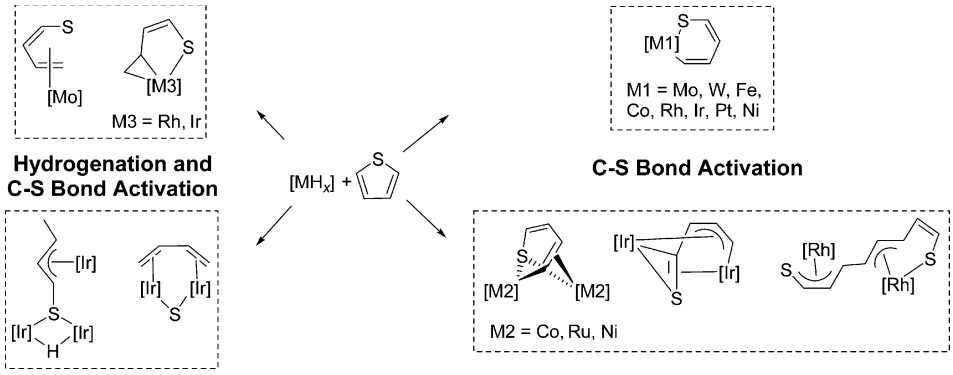

Scheme 1. Reported products obtained in the reaction of **T** with $[MH_x]$ ($x$ = 0–3) transition-metal complexes.

means of a dinuclear polyhydride iridium complex in the presence of a hydrogen acceptor compound.[45] Several intermediate species identified by NMR showed how the activation of the second C–S bond is subsequent to the hydrogenation of the thiophenic chain. Within this context, it is worth noting that in the examples where the first C–S bond activation is accompanied by hydrogenation (Scheme 1, left-hand side),[32,46,47] the complete desulfurization has usually required further treatment with $H_2$. However, the same reaction with the thiametalacycle products is unreported.

In this paper, a dinuclear polyhydride platinum complex was investigated for its ability to react with **T**. An approach followed in earlier studies of platinum-mediated desulfurization of thiophene, benzothiophene, and dibenzothiophene involved their reaction with $[(PEt_3)_3Pt]$ and subsequent treatment with various hydride reagents.[35] While the completely desulfurized hydrocarbons were obtained from the three heterocycles, the amount of desulfurization in the case of **T** was about 4%. Overall, the notion that two metal centers might be required for cleavage of both thiophenic C–S bonds,[16] the high HDS activity shown by platinum metals,[48,49] and the fact that a polyhydride complex already contains the hydrogen needed for thiophene hydrogenolysis led us to explore the reaction of $[(dppp)_2Pt_2H_3]ClO_4$ [dppp = 1,3-bis(diphenylphosphanyl)propane] with **T** and the mechanism of this reaction. Within the context of its possible relevance in the modeling of HDS studies, we first investigated the reactivity of $[(dppp)_2Pt_2H_3]ClO_4$ toward sulfur-containing species such as $Na_2S$ or NaSH. The set of reactions obtained provided solid evidence that behind the apparent simplicity of platinum complexes containing Pt–H, Pt–SH, or Pt–S fragments, there is an outstanding chemistry.[50]

## Results and Discussion

### Experimental Results

The reaction between $[(dppp)_2Pt_2H_3]ClO_4$ (**I**) and **T** was monitored by $^1H$ and $^{31}P$ NMR and mass measurements until no further progress was observed. Consistent with literature data,[35,36,45] high temperature, significant excess of thiophene with respect to the platinum complex, and several hours are required for optimum rate and yield. While under these experimental conditions we always observed the concomitant formation of two platinum complexes, their relative amounts were dependent on the presence or absence of benzene or toluene solvent. The isolation procedure and complete characterization of the complexes obtained are given in the Experimental Section.

### *The Reaction of $[(dppp)_2Pt_2H_3]ClO_4$ (I) with Thiophene*

Monitoring by $^{31}P$ NMR spectroscopy (Figure 1) indicated concomitant formation of a mononuclear and a dinuclear platinum species (Scheme 2). However, neither the NMR nor the ESI MS data gave evidence of intermediate species being formed. Similar observations were obtained in the monitoring of the reaction of **I** (0.15 mmol) with thiophene (15 mL) in toluene or benzene solvent (15–20 mL) at reflux temperature. The only difference in these reactions was the relative molar ratio of the two new platinum complexes formed (2:3 in neat thiophene and 1:9 in toluene or benzene). According to the $^{31}P$ and $^1H$ NMR spectroscopic data recorded during the reaction, both **II** and **III** not only form simultaneously but also maintain a constant molar ratio until the end of the reaction.

The $^{31}P$ NMR features of the reaction mixture that were attributable to a mononuclear platinum complex, literature data,[35,36] and the peak at $m/z$ = 692.2 in the ESI MS spectrum were consistent with the formation of an unsymmetrical species by insertion of the {(dppp)Pt} fragment into one thiophenic C–S bond. The formulation of this complex as $[(dppp)Pt(SC_4H_4\text{-}C,S)]$ (**II**) was fully confirmed by $^{31}P$, $^{195}Pt\{^1H\}$ and bidimensional $^1H$ and $^{13}C$ spectra (NOESY, COSY, HMQC C-H, and HSQC-edit C-H). $^1H$ and $^{13}C$ NMR spectroscopic data were consistent with those reported for the related $[(PEt_3)_2Pt(SC_4H_4\text{-}C,S)]$ complex.[35]

The remaining signals in the $^{31}P$ NMR spectrum of the reaction mixture, together with $^1H$ NMR and ESI MS data obtained during the monitoring of the reaction of **I** with **T** gave evidence that **III** was probably a dinuclear platinum complex. Full characterization of this complex after its isolation by column chromatography from crude mixture after 20 h of reaction allowed us to formulate it as $[(dppp)_2Pt_2(\mu\text{-}SC_4H_5\text{-}C,S)]ClO_4$ (**III**).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

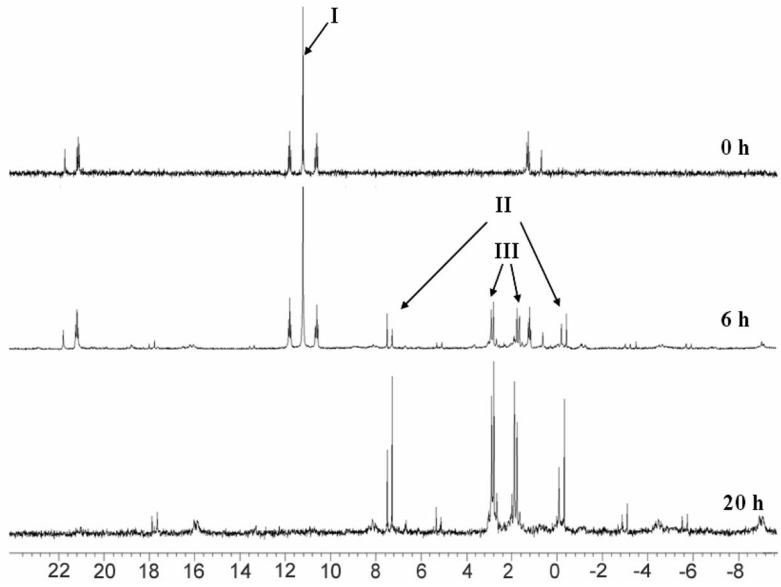

Figure 1. Monitoring by $^{31}P\{^1H\}$ NMR in $Cl_3CD$ of the reaction of $[(dppp)_2Pt_2H_3]ClO_4$ (**I**) with neat thiophene evidences formation of $[(dppp)Pt(SC_4H_4\text{-}C,S)]$ (**II**) and $[(dppp)_2Pt_2(\mu\text{-}SC_4H_5\text{-}C,S)]ClO_4$ (**III**) after 6 h, and total consumption of **I** after 20 h.

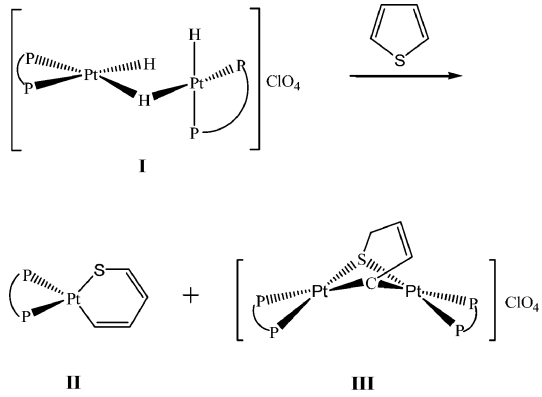


Scheme 2. The mono- and dinuclear platinum complexes obtained in the reaction of **I** with thiophene.

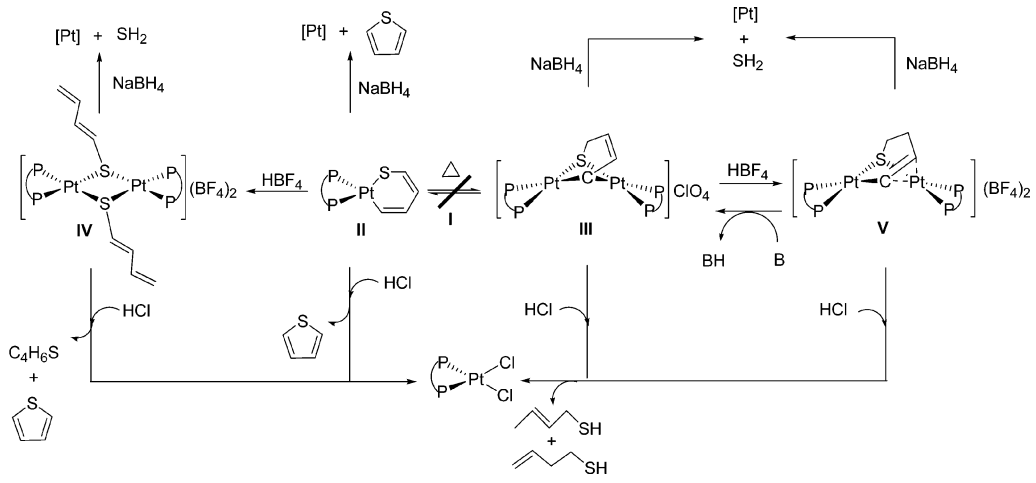
Thus, the $^{31}P\{^1H\}$ NMR spectrum of **III** is second-order, consisting of two broad signals (Figure 1) that fit well with the simulation of this spectrum including long-range P–Pt couplings (see electronic supporting information). Concerning the $^{195}Pt\{^1H\}$ NMR spectrum, it displays the same pattern as **II** with broader signals. These features corroborate the dinuclear nature of **III** and the symmetrical behavior of the bridging ligand. The $SC_4H_5$ ligand in **III** was fully characterized by $^1H$ NMR, with additional NOESY and COSY experiments, as well as by HMBC P–H, $^{13}C$ NMR (DEPT), and HSQC-edit C–H data. The $^{13}C$ chemical shifts at $\delta$ = 126.1 and 137.1 ppm, which are in the proper range for olefins, gave evidence of one double bond. This fact, in addition to the symmetry of the complex, even at low temperatures, allows an $\eta^3$ coordination for this bridge to be discarded and makes the formulation {S–$CH_2$–CH=CH–CH} the most reasonable alternative.[51] The stoichiometric ratio of dppp to $SC_4H_5$ ligands in **III** is 2:1, as deduced from the integration of the signals of the proton resonating at $\delta$ = 5.43 or 5.61 ppm (corresponding to the –CH=CH– fragment) with respect to those of the aliphatic $CH_2$ groups in the phosphane ligands, in agreement with the dinuclear nature of **III**. The absence of hydride ligands is fully confirmed by $^1H$ and HMBC Pt–H NMR, and agrees with infrared data. Finally, the ESI-MS spectrum shows a major peak at *m/z* = 1299.2401 $[M^+]$ that fits well to the $[(dppp)_2Pt_2(SC_4H_5)]^+$ cation. Elemental analyses and IR data are consistent with **III** being an ionic molecule with $ClO_4^-$ as counterion.

### *Additional Reactions*

In order to further elucidate the mechanism leading to **II** and **III**, and to further analyze the reactivity of these complexes, we carried out complementary reactions. These were monitored for several hours by $^{31}P$ and $^1H$ NMR as earlier described for the reaction of **I** with **T**. In some reactions the deuterated analog of **I**, $[(dppp)_2Pt_2D_3]ClO_4$ (**I-*d*$_3$**), was employed, and in these cases $^2H$ NMR spectra were also recorded. The synthesis and NMR features of **I-*d*$_3$** have already been reported.[50] On the whole the NMR features allowed identification of the compounds formed and eventually led to the synthesis and characterization of new complexes, as depicted in Scheme 3.

The reactions involving **I-*d*$_3$** gave evidence that complex **I** cleaves in the presence of thiophene. Thus, the heating at reflux temperature of a 1:1 mixture of **I** and **I-*d*$_3$** in the presence of thiophene showed that after 6 h all isotopomers $[(dppp)_2Pt_2H_{(3-x)}D_x]^+$ ($x$ = 0–3) were present in comparable amounts. However, when the same process was carried out in the absence of thiophene, only negligible amounts of mixed species were present after 12 h of heating. This indicated that **T**, and not the presence of solvent, causes the cleavage of **I**, and that the breaking of the dinuclear platinum complex **I** is a reversible process, both issues being

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 



Scheme 3. Overall reactivity of complexes **I**–**V**: (a) No interconversion between **II** and **III** is observed; (b) **II** with $HBF_4$ affords **IV** and, similarly, **III** gives **V**; (c) **V** goes back to **III** by addition of a base (B = $MeO^-$, $Et_3N$); (d) complexes **II**–**V** react with HCl, and also with $NaBH_4$, but not with **I**.

consistent with literature data.[32] In addition to the above reactions, the use of **I-*d*$_3$** provided information on the source and location of the inserted hydrogen atom into the thiophenic chain of **III**. This was obtained by the reaction of **I-*d*$_3$** and **T** in toluene at reflux temperature, which afforded **II** and **III-*d*$_1$**. Characterization of **III-*d*$_1$** by $^1H$, $^2H$, and $^{13}C$ DEPT-135 NMR spectroscopic data allows to establish that deuterium is bound to the carbon atom next to the sulfur atom.

Another set of experiments, aimed at examining whether **II** and **III** could convert into each other even though their concentrations increased concomitantly during the reaction of **I** with **T**, both in the presence and absence of toluene or benzene solvent, was indicative of parallel reaction pathways. Within this context, **II** and **III** were independently heated in toluene solvent at reflux temperature for several hours, during which no changes were observed. The same procedure with a mixture of **I** (as a possible platinum and hydride source) and **II** at various molar ratios in toluene did not afford **III**, thus reinforcing that **II** and **III** are independently formed.

While the reaction of **I** with **T** involves the activation of one C–S bond of thiophene, the conditions for the cleavage of the second S–C bond in **II** and **III** were also examined. To this end, complexes **II** and **III** were made to react with protonic acids ($HBF_4$, HCl) and hydride sources ($NaBH_4$, **I**). These reactions are summarized in Scheme 3 and the corresponding conditions given in the Exp. Section.

### *The Reaction of II and III with HBF$_4$*

The reaction of **II** with $HBF_4$ yielded the di-μ-thiolato dinuclear complex $[(dppp)_2Pt_2(\mu\text{-}SC_4H_5)_2](BF_4)_2$ (**IV**) in high yield. Identification of this complex was achieved on the basis of NMR spectroscopic data, which were fully consistent with those reported for the $[(PEt_3)_4Pt_2(\mu\text{-}SC_4H_5)_2](BF_4)_2$ analog, also obtained in a parallel reaction.[52]

Remarkably, replacement of **II** by **III** in the above reaction led to the unprecedented complex $[(dppp)_2Pt_2(\mu\text{-}SC_4H_6)](BF_4)_2$ (**V**), whose formation involves the insertion of a proton in the thiophenic chain of **III** without cleavage of the dinuclear species. As shown in Scheme 3, this reaction is easily reversed by addition of a base (NaMeO, $NEt_3$). Characterization of **V** by solution NMR measurements at room temperature evidenced the symmetrical behavior of the bridging ligand with respect to the two platinum centers. It also allows to establish that the proton insertion in the bridging S–$CH_2$–CH=CH–CH ligand in **III** causes an electronic rearrangement leading to a S–$CH_2$–$CH_2$–CH=CH species in **V**. As a result, one of the two σ Pt–C5 bonds in **III** evolved into a π interaction with the C4=C5 double bond in **V**, consistently with $^1H$ and $^{13}C$ NMR spectroscopic data. However, the symmetry observed in the latter complex for the phosphorus nuclei in the $^{31}P\{^1H\}$ NMR spectrum indicated a fluxional behavior for the CH=CH ligand moiety, which was consistent with low-temperature $^{31}P\{^1H\}$ NMR spectroscopic data. These showed that the two signals corresponding to the phosphorus nuclei, particularly that at $\delta$ = 0.1 ppm, widen with decreasing temperature without reaching complete decoalescence. According to the structure determined by single-crystal X-ray diffraction (see below), the features above are consistent with a fluxional behavior for the bridging ligand, which involves the σ Pt–C5 bond and the C4=C5 double bond to exchange sites between the two platinum centers.

### *The Reaction of II–V with HCl*

The reaction of **II**–**V** with a slight excess of HCl always led to the separation of solid $[(dppp)PtCl_2]$ in high yield (about 75%). The ease of formation of this complex in related systems is well known.[52] In the case of **III**–**V**, various thiols were also detected in the reaction mixture by CG-MS, as depicted in Scheme 3. Thiophene was also identified in the reaction of **IV**, and it was the only additional product in the case of **II**, both results being consistent with reported data.[52]

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Overall, the reaction of **II**–**V** with $HBF_4$ or HCl does not involve activation of the second thiophenic C–S bond. Instead, these reactions allow the formation of thiols and, in the case of HCl, the recovery of platinum as [(dppp)-$PtCl_2$].

### *The Reaction of II–V with I and $NaBH_4$*

Complexes **II**–**V** did not react with **I** in toluene at reflux temperature but started degrading after 12 h of heating, as evidenced by the darkening of the reaction mixture, which was attributed to the formation of $Pt^0$. The same features were observed in the attempts to treat **II**–**V** with $NaBH_4$ at room temperature. However, with $NaBH_4$ the darkening of the solution was accompanied by the formation of either **T** (**II**) or $H_2S$ (**III**–**V**), the former detected by GC-MS, and the latter by formation of silver sulfide. Significantly, no other sulfur-containing species were identified in these reactions.

On the basis of the reactions above, it becomes apparent that the activation of the second thiophenic S–C bond by hydride sources is only achieved in compounds **III**–**V**. The reluctance of this bond to be activated in **II** is probably due to the greater aromatic character of the corresponding thiametalacycle. In fact, the cleavage of the C–S bond in **II** requires previous treatment with protons in the presence of noncoordinating counterions ($HBF_4$), which leads to **IV**. Overall, the activation of the C–S bond in **II**–**V** by $NaBH_4$ involves the total decomposition of these complexes.

### X-ray Structure of the $[(dppp)Pt(\mu\text{-}SC_4H_6)Pt(dppp)]^{2+}$ Cation

The structure showed evidence of a twinned crystal having two components related by a twofold rotation along the reciprocal axis *c**. The asymmetric unit of the unit cell contains two cations $[(dppp)Pt(\mu\text{-}SC_4H_6)Pt(dppp)]^{2+}$ together with three $BF_4^-$ and one $ClO_4^-$ anions, three acetone and one water molecules.[53] As the bonding parameters of the two cations are comparable, the geometry and selected bond lengths and angles given in the text correspond to one of them (Figure 2, Tables 1 and 2).

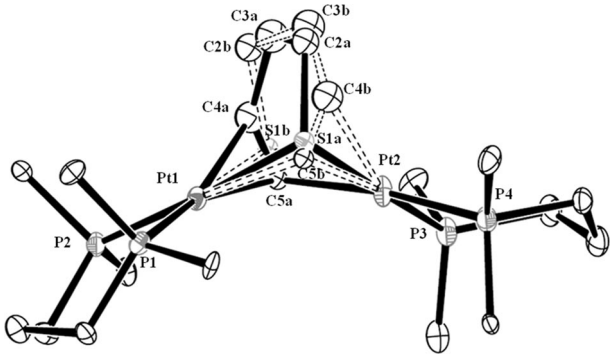


Figure 2. Structure of the cation in complex **V** with 50% probability displacement ellipsoids showing the two opposite orientations (a/b) of the thiolate bridge. Anions, hydrogen atoms, and phenyl rings are omitted for clarity.

[a] The A/B labels refer to the two disordered $SC_4H_6$ fragments.

While the solution of the structure of the cation showed evidence of disorder of the bridging $SC_4H_6$ ligand, on the basis of the NMR spectroscopic data already described it was modeled as S–$CH_2$–$CH_2$–CH=CH. On the other hand, crystallographic resolution of a related cobalt complex[41] allowed us to consider that there were two bridging ligands with opposite orientation, in which the sulfur and C=C double bond exchange sites and the double bond changes the platinum atom, to which it is $\eta^2$-bound (effectively a $C_2$ rotation of the $SC_4H_6$ group perpendicular to Pt–Pt axis). Moreover, there was no evidence for disordered atoms corresponding to {(dppp)Pt} moieties, suggesting that these

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

atoms lie in virtually the same locations in the disordered partners.

The bond lengths and angles observed for the $SC_4H_6$ ligand are fully consistent with the sequence S–$CH_2$–$CH_2$–CH=CH, whose atoms are puckered in such a fashion so that sulfur, C2, C3, and C4 are nearly planar, but with C5 lying above this plane. While one of the platinum atoms (Pt1) is bound to the $SC_4H_6$ bridge through sulfur and the C4=C5 double bond, the other platinum (Pt2) binds to the same sulfur but only to C5 through a σ bond. As a result of the different coordinative behavior of the bridging ligand, two different square-planar environments are observed for the platinum centers. The platinum–platinum distance of 3.2272(6) Å is consistent with the only reported related species, where a weak metal–metal interaction is proposed.[54] Concerning the terminal dppp ligands, they adopt a distorted chair conformation that compares very well with that usually found in dinuclear complexes enclosing different bridging ligands between two {(dppp)$Pt^{II}$} fragments.[55] This is the first structurally characterized example of a dinuclear platinum compound resulting from the S–C activation of thiophene.

## Computational Study of the Reaction Mechanism of I with T

Computational chemistry has proven to be a useful tool in mechanistic studies of homogeneous catalytic processes.[56,57] However, theoretical analyses of HDS mechanisms using organometallic reagents are still scarce,[43,44] and in general have focused on investigating the nature and energetics of the interactions between **T** and single-metal organometallic complexes.[58–64] In this section we present a complete computational study of the reaction mechanism of **I** with **T** using DFT methods. From this study and the experimental results presented above we propose a plausible reaction pathway for the formation of complexes **II** and **III**.

All complexes have been modeled using $H_2P(CH_2)_2PH_2$ (dhpp) instead of the actual dppp ligand. The calculated intermediates are numbered from **1** to **10** and the transition states are labeled as **TS1**, **TS2**, and so forth. The van der Waals complexes are indicated by **2a···2b** while **2a+2b** indicates the sum of the energies of the individual species. Given the cationic nature of some intermediates, the inclusion of solvent is mandatory to obtain a reliable energy profile. Thus, the relative energies of intermediates and reaction barriers calculated in benzene are given in the schemes. The resulting $\Delta G$ values in benzene and details of geometries of the transition states are given in the electronic supporting information.

### *Fragmentation of the Dinuclear [(dhpp)$_2$Pt$_2$H$_3$]$^+$ Cation (1)*

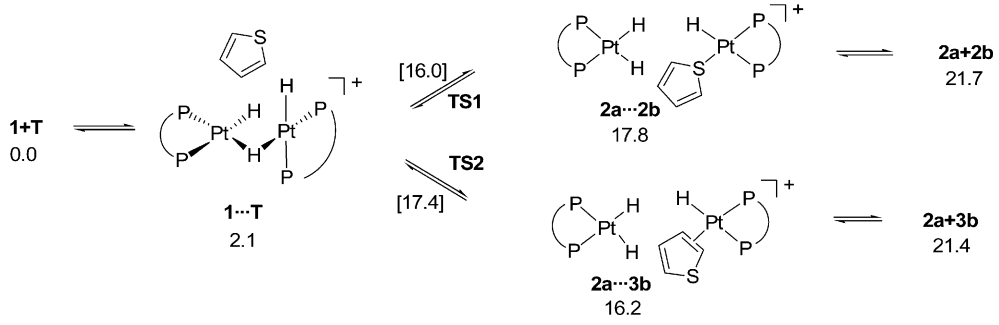
All attempts to make **1** react with **T** have led to the cleavage of the dinuclear platinum complex with the concomitant coordination of **T** to one of the platinum centers. In this way two mononuclear $Pt^{II}$ complexes are formed: [(dhpp)$PtH_2$] (**2a**) and either [(dhpp)PtH($C_4H_4S$-κ*S*)]$^+$ (**2b**) or [(dhpp)PtH($\eta^2$-$C_4H_4S$)]$^+$ (**3b**), depending on whether the coordination mode of thiophene to platinum is through sulfur or a double bond, respectively. As shown in Scheme 4, both types of coordination involve similar energy barriers: 16.0 kcal/mol (**TS1**) to give **2a** and **2b**; and 17.4 kcal/mol (**TS2**) to give **2a** and **3b**. Also, both pathways are clearly endothermic, the products being 21 kcal/mol above reactants.

The energy for the cleavage of **1** was also calculated in the absence of **T** in order to quantify the thiophene assistance to the fragmentation process. The energy cost associated to the formation of [(dhpp)PtH]$^+$ and [(dhpp)$PtH_2$] (**2a**) from [(dhpp)$Pt_2H_3$]$^+$ in benzene is 39.5 kcal/mol, thus, considerably higher than in the presence of thiophene (21.7 kcal/mol).

### *Formation of [(dhpp)Pt($C_4H_4$S-C,S)] (6a)*

Both **2a** and **2b** species are candidates to afford the {(dhpp)$Pt^0$} fragment, which is the precursor of **6a** (**II**). However, theoretical calculations show that formation of this fragment by reductive elimination of $H_2$ from **2a** is much more easily achieved than the elimination of a *S*-protonated thiophene from **2b**. The calculated energy for the latter reaction is 69.5 kcal/mol, too high to be feasible. Consequently, only the reaction from **2a** to yield **6a** has been taken into account. Concerning energy values, as **2a** and **2b** can exist as separate entities in solution, they are taken as the zero of energy in the following discussions.

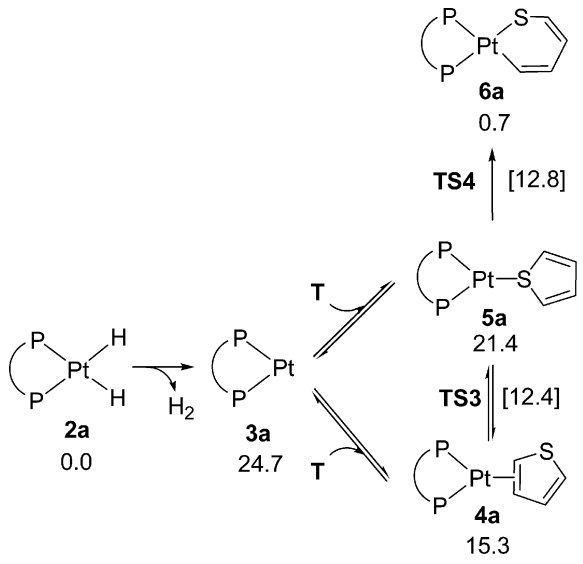
The set of reactions that account for the evolution from **2a** to **6a** (Scheme 5) is initiated by the concomitant re-



Scheme 4. Reaction pathway proposed for the fragmentation of **I** (**1**). Relative energies of intermediates and energy barriers (in brackets) are included. All values calculated in benzene solvent [kcal/mol].

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

duction of platinum and elimination of $H_2$ (**2a**) to give [(dhpp)Pt] (**3a**), which is 24.7 kcal/mol less stable than **2a**. This is consistent with already reported experimental[65–67] and theoretical[68,69] studies. The energy barrier for the $H_2$ elimination is given by the energy difference between **3a+H$_2$** and **2a**. However, as this energy increases monotonously along the $H_2$ elimination process, the TS cannot be found. This dissociative reaction is entropically favored and, consequently, considering $\Delta G_{benzene}$ values, **3a+H$_2$** lie only 14.5 kcal/mol above **2a**.



Scheme 5. Reaction pathway proposed for the formation of **II** (**6a**). Relative energies of intermediates and energy barriers (in brackets) are included. All values calculated in benzene solvent [kcal/mol].

The next step is the coordination of thiophene to **3a**, which, analogously to the [(dhpp)PtH]$^+$ fragment (Scheme 4), can occur through either the sulfur atom or the double bond, thus forming [(dhpp)Pt($C_4H_4S$-κ*S*)] (**5a**) or [(dhpp)Pt($\eta^2$-$C_4H_4S$)] (**4a**), respectively. The conversion of **4a** to **5a** is possible through an energy barrier of 12.4 kcal/mol (**TS3**). In addition, despite **4a** being more stable than **5a** (see Scheme 5), the oxidative addition of platinum to the C–S bond requires that **T** is bound through sulfur. The energy barrier for the oxidative addition process is 12.8 kcal/mol (**TS4**). Considering the two steps ($H_2$ elimination + C–S insertion), **TS4** lies 34.2 kcal/mol above **2a**. However, the insertion product [(dhpp)Pt($C_4H_4S$-*C*,*S*)] (**6a**, Scheme 5) is remarkably stable, as shown by the exothermicity of the insertion process (from **3a** to **6a**).

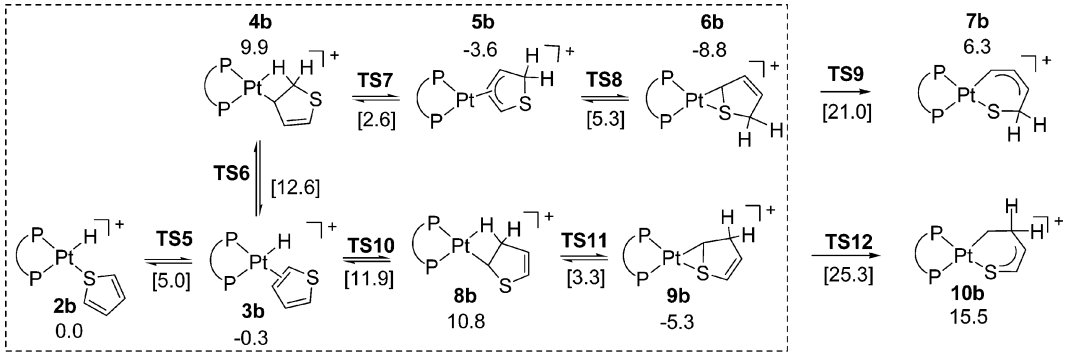
### *Transfer of Hydride from the Metal to Thiophene*

The cationic complex **2b** formed in the first step of the reaction (Scheme 4) follows a different route than **2a**. First, the apparent rotation of thiophene from κ*S* to $\eta^2$-*C*,*C* coordination mode gives way to complex [(dhpp)PtH($\eta^2$-$C_4H_4S$)]$^+$ (**3b**), with an energy barrier of 5.0 kcal/mol (**TS5**) (Scheme 6). Complex **3b** can also be formed by direct reaction of **1** with **T** through **TS2** (Scheme 4).

Once **3b** is formed, the hydride migration to the double bond in C2 or C3 becomes feasible. The migration to C2 gives an agostic intermediate **4b** with an energy barrier of 12.6 kcal/mol (**TS6**). In going from **4b** to **5b** the agostic interaction is lost and the thiophene ring rotates in order to adopt $\eta^3$ coordination. The energy cost of this process is very low, only 2.6 kcal/mol (**TS7**). Finally, from **5b** a subsequent rotation of the thiophene ring with an energy barrier of 5.3 kcal/mol (**TS8**) gives the most stable conformation of this system (**6b**), 8.8 kcal/mol more stable than **2b**. In **6b** the platinum is bonded to C5 and to the sulfur, and the π system has been rearranged.

From **3b** the hydride migration to C3 proceeds in a similar way, with an energy barrier of 11.9 kcal/mol. After the first transition state (**TS10**) an agostic intermediate **8b** is formed. The rotation of the thiophenic group in this case gives compound **9b**, where Pt is bonded to the C2 and sulfur atoms. This product is 5.3 kcal/mol more stable than **2b**.

Considering the energy barriers for the hydride transfer and for the thiophene ring rotation, all species displayed in Scheme 6 within the dashed-line square are in equilibrium with each other, although it is displaced towards formation of **6b**. From this complex, the C–S bond activation of thiophene to give complex **7b** is accessible with an energy barrier of 21.0 kcal/mol. The C–S bond activation from the less stable complex **9b** was also considered. This activation not only has a higher energy barrier (25.3 kcal/mol), but also it is a more endothermic reaction. Thus, while **7b** is 6.3 kcal/mol above **2b**, **10b** is 15.5 kcal/mol, so the activated product **7b** is clearly favored with respect to **10b**.



Scheme 6. Reaction pathway proposed for hydride insertion in **2b**. Relative energies of intermediates and energy barriers (in brackets) are included. All values calculated in benzene solvent [kcal/mol].

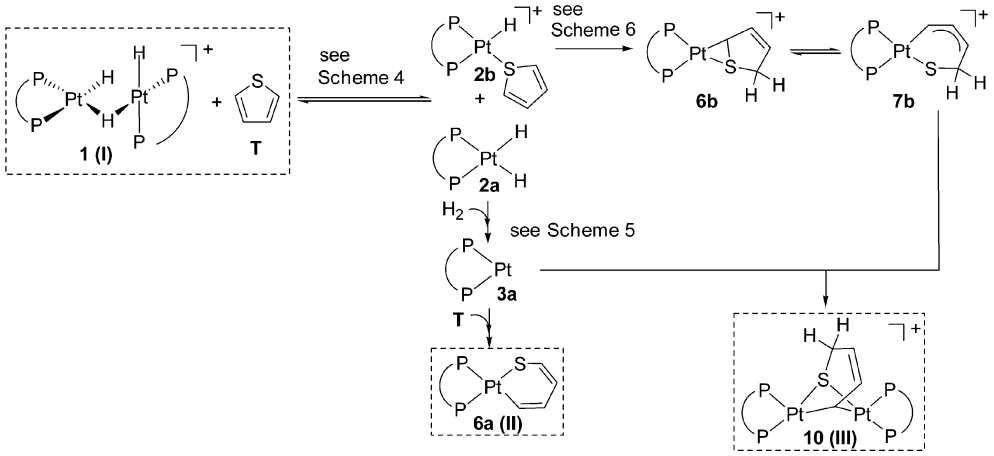

Scheme 7. Reaction pathways proposed for the formation of **6a** (**II**) and **10** (**III**).

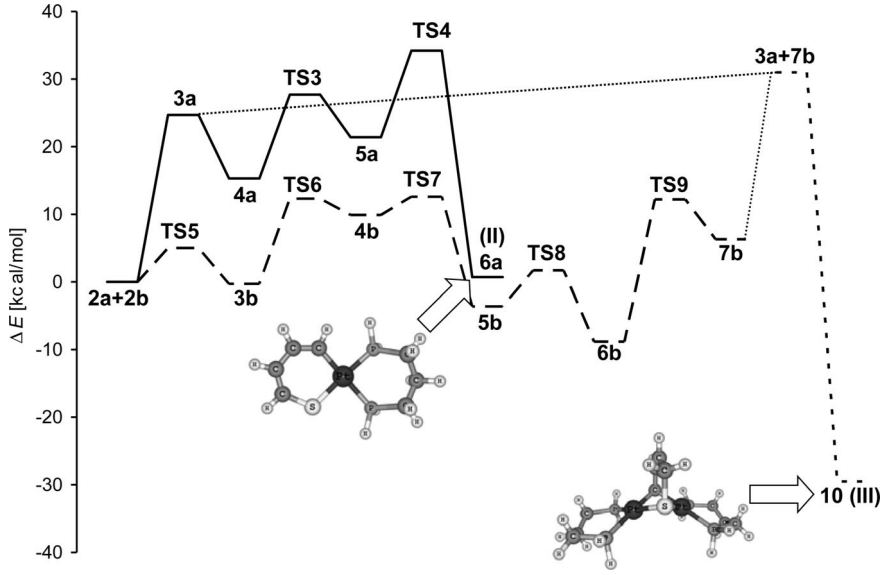

Figure 3. Energy profile of the reaction leading to complexes **6a** (**II**) and **10** (**III**), showing the pathway: (a) from the dissociation of **1** (**2a+2b**) either to product **6a** or to intermediate **7b**, by means of plain or discontinuous lines, respectively, and (b) from **3a+7b** to **10** by dotted lines.

### *Formation of the [(dhpp)Pt(μ-SC$_4$H$_5$-C,S)Pt(dhpp)]$^+$ Cation (10)*

Up to now the successive pathways leading to complexes **6a** and **7b** have been considered separately (Schemes 4, 5, and 6). In this subsection they will be assembled to enable the formation of **10**, model of the experimental complex **III**. The overall mechanism is summarized in Scheme 7, where the complexes described in the experimental section are highlighted within dashed-line squares. The energy profile for the sequence of reactions that take place after fragmentation of **I** to finally afford **6a** and **10** is depicted in Figure 3.

As shown in Scheme 7, fragmentation of the dinuclear platinum trihydride leads to **2a** and **2b**. At this point, these complexes react through different pathways. On the one hand, complex **2a** undergoes $H_2$ elimination to give **3a**, which subsequently reacts with thiophene to yield **6a** (**II**). On the other, the hydride migration to C2 in complex **2b** (more favored than to C3) leads to **6b**. This intermediate is able to activate the C–S bond to give the very unstable **7b** complex. Reaction of the latter species with **3a** gives the dinuclear platinum complex **10** without energy barrier (Figure 3). The energy of this complex is 29.5 kcal/mol below that of **2a+2b** and, despite the unfavorable entropic contribution of the association process, the **2a+2b** → **10** reaction is also favored on Gibbs energy grounds with $\Delta G_{benzene}$ = –20.8 kcal/mol.

### Calculations versus Experiments

All previous considerations account for the overall mechanism from **1** (**I**) to either **6a** (**II**) or **10** (**III**). The next step is to analyze their consistency with the experimental results. Thus, concerning the reaction of **I** with **I-$d_3$**, the formation of a mixture of isotopomers **I-$d_x$** ($x$ = 0–3) was

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

experimentally observed only in the presence of thiophene at reflux temperature. This is consistent with the equilibrium between **1+T** and **2a+2b** depicted in Scheme 4. This reaction has an energy cost of 21.7 kcal/mol while the fragmentation of **I** without the presence of thiophene requires 39.5 kcal/mol. On the other hand, replacement of **I** by **I-*d*$_3$** in the synthesis of **III** showed that the hydrogen atom inserted into the thiophenic ring comes from **I** and adds to the C2 atom. This result fits well with the mechanism showed in Scheme 7, in which the formation of **10** (**III**) involves an initial insertion of the hydride into the C2 position of the coordinated thiophene in **2b**.

The general mechanism proposed can also account for the noninterconversion between **II** and **III** even in the presence of external hydride ligands. Comparison of **II** and **III** indicates that this transformation would imply the hydride insertion into the thiophenic ring of **II** and the subsequent coordination of an additional {(dppp)Pt} fragment. On the basis of Scheme 7, two steps leading to **III** deserve special consideration. First, the intramolecular hydride migration in species **2b**, which entails a low energy barrier, and second, the stabilization of the intermediate **7b** by means of its coordination to a {(dppp)Pt} fragment. Remarkably, none of these two features can be accomplished in the experimental system. On the one hand, **II** does not enclose platinum-bound hydride ligands, thus hampering an intramolecular hydride migration. On the other, formation of **III** would require the assistance of the {(dppp)Pt} fragment, which only forms from the thiophene-promoted dissociation of **I**. Overall, theoretical results account for the fact that **II** does not evolve into **III**, even in the presence of **I** or $NaBH_4$.

Another experimental feature of the reaction of **I** with **T** refers to the different relative amounts of the reaction products, **II** and **III**, depending on the reaction conditions. Thus, the reaction affords **II** (**6a**) and **III** (**10**) in a 2:3 or 1:9 molar ratio using neat thiophene or organic solvent (toluene or benzene), respectively. The energy profile depicted in Figure 3 shows that the highest energies involved in the formation of **6a** and **10** (**TS4**: 34.2 kcal/mol and **3a+7b**: 31.0 kcal/mol, respectively) are very similar. Consequently, small changes in the reaction conditions can affect these energies, modifying the molar ratio of products. In addition, the concentration of thiophene also influences the **II** to **III** molar ratio because the two parallel pathways leading to **6a** and **10** involve a different number of thiophene molecules. The minor relative amount obtained for **II** in benzene or toluene can be explained considering that two molecules of **T** are required to form this complex, one to dissociate the starting complex **1** and the other to react with **3a** (see Scheme 7). Overall, the formation of **II** in toluene or benzene will be disfavored versus **III**, whose formation requires only one molecule of **T**.

## Conclusions

C–S bond activation of thiophene (**T**) by the dinuclear trihydride platinum complex $[(dppp)_2Pt_2H_3]ClO_4$ (**I**) afforded the mononuclear [(dppp)Pt($SC_4H_4$-*C*,*S*)] (**II**) metalacycle that involves activation of the thiophenic C–S bond exclusively, and the dinuclear $[(dppp)_2Pt_2(\mu\text{-}SC_4H_5\text{-}C,S)]ClO_4$ (**III**) complex, where activation of this bond is concomitant with the partial hydrogenation of thiophene (Scheme 2).

Additional experiments and computational results have evidenced the role of **T** as promoter of the cleavage of **I** into the [(dppp)$PtH_2$] and $[(dppp)PtH(C_4H_4S\text{-}\kappa S)]^+$ fragments in the first step of the reaction. Also, experimental observations showing the noninterconversion equilibrium between **II/III** indicate that two concurrent mechanisms are at work. This is fully consistent with the theoretical calculations, which allow us to propose two different reaction pathways that originate after the dissociation of **I**. While formation of **II** involves exclusive participation of the former fragment, both are required to take part in the pathway leading to **III**. In fact, formation of this complex implies the coordination of {(dppp)Pt} to $[(dppp)Pt(\mu\text{-}SC_4H_5\text{-}C,S)]^+$ (Scheme 7). The former species, which originates from [(dppp)$PtH_2$], is responsible for the stabilization of the latter, which arises from the hydride migration into the thiophenic ring in $[(dppp)PtH(C_4H_4S\text{-}\kappa S)]^+$ and subsequent C–S bond activation. Remarkably, complex **III** is the first example of a platinum complex involving C–S bond activation and hydrogenation of thiophene.

The reactions of platinum complexes **II**–**V** with protonic acids and hydride sources have shown the ability of these reagents to give total desulfurization (Scheme 3). Thus, the reaction of **II** and **III** with protonic acids affords either partial hydrogenation of the thiophenic chain (with $HBF_4$) or formation of thiols (with HCl). On the other hand, the reaction with $NaBH_4$ entails the formation of $H_2S$ only from complexes where the thiophenic chain has been partially hydrogenated (**III**–**V**). This result is consistent with the assumption that metal hydride complexes are keystones in the desulfurization of thiophene.

Overall, the combination of experimental and theoretical studies of the reaction of $[(dppp)_2Pt_2H_3]ClO_4$ with thiophene has provided new insights into the mechanism of the homogeneous HDS. Notwithstanding this progress, designing systems able to perform the reaction of completely and efficiently desulfurizing thiophene and in softer conditions still appears to be the main goal. The importance of this reaction makes any effort in this direction worthwhile.

## Experimental Section

**Materials and Methods:** All reactions were carried out under pure dinitrogen, and conventionally dried and degassed solvents were used throughout. These were Purex Analytical Grade from SDS. Thiophene (≥99%) was purchased from Aldrich. It was purified following a reported procedure.[70] Commercial 0.5 M NaMeO in methanol and $NEt_3$ (99%, $d$ = 0.726 g/cm$^3$) were used without further purification. The synthesis and spectroscopic characterization of $[(dppp)_2Pt_2H_3]ClO_4$ (**I**) and $[(dppp)_2Pt_2D_3]ClO_4$ (**I-*d*$_3$**) as well as the X-ray structure of **I** have already been reported.[50] Elemental

analyses were performed on a Carlo–Erba CHNS EA-1108 analyzer. IR spectra were recorded with a Perkin–Elmer FT-2000 spectrophotometer using KBr pellets. $^{1}H$, $^{1}H\{^{31}P\}$, $^{13}C$ DEPT, $^{31}P$, $^{31}P\{^{1}H\}$ $^{31}P$–$^{1}H$ HMBC, $^{195}Pt$, and $^{195}Pt\{^{1}H\}$ NMR and $^{1}H$–$^{1}H$ NOESY, $^{1}H$–$^{1}H$ COSY, $^{13}C$–$^{1}H$ HMQC, and $^{13}C$–$^{1}H$ HSQC-edit spectra were performed unless otherwise indicated from samples in solution at room temperature with a Bruker Avance DRX-360 spectrometer operating at 360.13 MHz for $^{1}H$, 90.56 MHz for $^{13}C$, 145.79 MHz for $^{31}P$, and 77.42 MHz for $^{195}Pt$. $^{1}H$ and $^{13}C$ chemical shifts are relative to $SiMe_4$, $^{31}P$ to external 85% $H_3PO_4$, and $^{195}Pt$ to external 1 M $Na_2[PtCl_6]$ in $D_2O$. The $^{31}P\{^{1}H\}$ NMR spectrum of **III** was simulated on a Pentium®-200 computer using the gNMR V4.0.1 program.[71] $^{2}H$ NMR experiments were performed from samples in $CDCl_3/CHCl_3$ mixture solutions at room temperature with a Bruker Avance-500 operating at 76.75 MHz. $^{2}H$ NMR chemical shifts are relative to $CDCl_3$. $^{19}F$ NMR experiments for **IV** and **V** were performed from samples in acetone solutions at room temperature with a Bruker DPX-250 operating at 235.33 MHz. $^{19}F$ NMR chemical shifts are relative to $CFCl_3$. H and C labels for complexes **III**–**V** are shown in Figure 4.

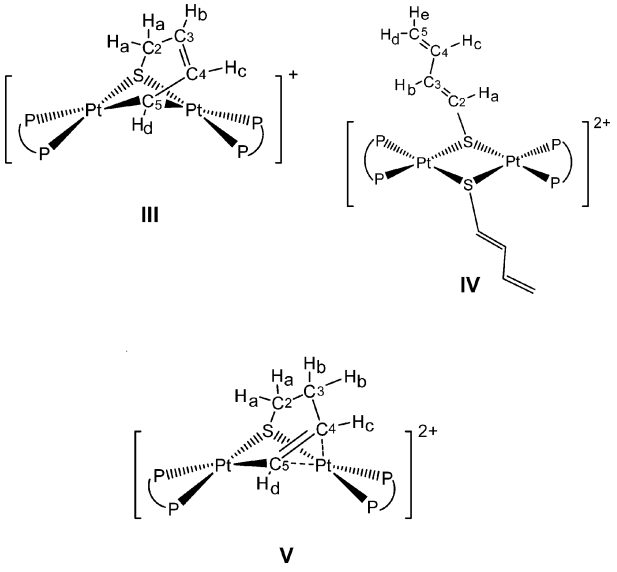

Figure 4. H and C labels for complexes **III**–**V**.

The ESI-MS measurements were performed on a VG Quattro Micromass Instrument under already described experimental conditions.[50] The carrier was a 1:1 mixture of acetonitrile and water containing formic acid (1–10%). The exact mass for **III** was determined on a micrOTOF-Q instrument using direct injection from HPLC 1200RR and Apollo II ESI ionization source. GC-MS spectra were recorded using a Hewlett–Packard 6890 instrument and a Hewlett–Packard 5973 electronic impact mass detector.

**Caution:** *Although no problems were encountered in this work, all perchlorate compounds are potentially explosive, and should be handled in small quantities and with great care!*

**Synthesis of [(dppp)Pt($SC_4H_4$-*C*,*S*)] (II):** The white-beige suspension formed by addition of **I** (200 mg, 0.15 mmol) to degassed neat thiophene (15 mL) was heated at reflux temperature (100 °C) for 24 h, by which time it had turned into a red-brown solution containing a minor amount of a black solid residue. This was separated by filtration through Celite and the remaining solution evaporated under vacuum to yield a brown residue. This solid was dissolved in toluene and the solution chromatographed on a neutral alumina column. Elution with a hexane/benzene mixture at 20% ratio showed separation of two bands, yellow and red-brown, which respectively contained complexes **II** and **III**. Extraction of the former band followed by removal of the solvent under vacuum produced a residue that was dissolved in acetone and precipitated with diethyl ether. The yellow solid thus formed was collected by filtration, washed with diethyl ether, and vacuum dried. Yield 52 mg, 25%. $^{1}H$ NMR (360 MHz, $CDCl_3$, 25 °C): $\delta$ = 6.75 (t, 1 H, CH), 6.92 (1 H, CH), 7.18 (1 H, CH), 7.34 (1 H, CH) ppm. $^{13}C$ DEPT NMR (91 MHz, $CDCl_3$, 25 °C): $\delta$ = 119.1 (CH), 120.8 (CH), 124.4 (CH), 130.2 (CH) ppm. $^{31}P\{^{1}H\}$ NMR (146 MHz, $CDCl_3$, 25 °C): $\delta$ = 6.56 (d, $^{1}J_{Pt,P}$ = 3064.4, $^{2}J_{P,P}$ = 33.0 Hz), –1.10 (d, $^{1}J_{Pt,P}$ = 1601.8, $^{2}J_{P,P}$ = 33.0 Hz) ppm. $^{195}Pt$ NMR (77 MHz, $CDCl_3$, 25 °C): $\delta$ = –4525 (dd, $^{1}J_{P,Pt}$ = 3066 and 1605 Hz) ppm. ESI-MS: *m*/*z* = 692.2 $[M + 1]^+$. $C_{31}H_{30}P_2PtS$ (691.2): calcd. C 53.83, H 4.37, S 4.64; found C 53.95, H 4.29, S 4.75. Attempts to obtain crystals suitable for X-ray diffraction were unsuccessful.

**Synthesis of [(dppp)$_2$Pt$_2$(μ-$SC_4H_5$-*C*,*S*)]$ClO_4$ (III):** The same reaction procedure as for **II** but in the presence of toluene or benzene led essentially to **III**. Thus, **I** (200 mg, 0.15 mmol) and neat thiophene (15 mL) were made to react in degassed toluene or benzene (20 mL). Column chromatography under the same experimental conditions as above allowed elution of the second red-brown band with benzene. Removal of the solvent under vacuum produced a residue that was dissolved in acetone and precipitated with diethyl ether. The precipitated yellow-brown solid was collected by filtration, washed with diethyl ether, and vacuum dried. Yield 83 mg, 43%. $^{1}H$ NMR (360 MHz, [$D_6$]acetone, 25 °C): $\delta$ = 1.62 (br., 2 $H_a$), 2.77 (br., $H_d$), 5.36 (dt, $^{3}J_{Hb,Ha}$ = 3.6, $^{3}J_{Hb,Hc}$ = 9.4 Hz, $H_b$), 5.46 (dt, $^{3}J_{Hc,Hb}$ = 9.4, $^{3}J_{Hc,Hd}$ = 8.2 Hz, $H_c$) ppm. $^{13}C$ DEPT NMR (91 MHz, [$D_6$]acetone, 25 °C): $\delta$ = 33.0 (C2), 42.7 (C5), 126.1 (C3), 137.1 (C4) ppm. $^{31}P\{^{1}H\}$ NMR (146 MHz, [$D_6$]acetone, 25 °C): $\delta$ = 3.02 (d, $^{1}J_{Pt,P}$ = 3869.6 Hz), 1.96 ($^{1}J_{Pt,P}$ = 1857.0 Hz) ppm. On the basis of the simulation of the $^{31}P\{^{1}H\}$ NMR spectrum including long-range P–P and P–Pt couplings: $^{3}J_{P',P'}$ = 22.0, $^{3}J_{P',P''}$ = 4.7, and $^{2}J_{P',P''}$ = –22.3 Hz, where P′ and P′′ are nonequivalent phosphorus nuclei, and $^{2}J_{P,Pt}$ = 56 Hz ($\delta_P$ = 1.96 ppm) and 37 Hz ($\delta_P$ = 3.02 ppm). $^{195}Pt\{^{1}H\}$ NMR (77 MHz, [$D_6$]acetone, 25 °C): $\delta$ = –4670 (dd, $^{1}J_{P,Pt}$ = 3872 and 1867 Hz) ppm. ESI-MS: *m*/*z* = 1299.2401 $[M - ClO_4]^+$. $C_{58}H_{57}ClO_4P_4Pt_2S$ (1399.64): calcd. C 49.77, H 4.10, S 2.29; found C 49.02, H 3.82, S 2.11. IR ($cm^{-1}$): $\tilde{\nu}$ = 1094 i, br. ($ClO_4$). Attempts to obtain crystals suitable for X-ray diffraction were unsuccessful.

Replacement of **I** by **I-*d*$_3$** in the above reaction procedure allowed unequivocal identification of $[(dppp)_2Pt_2(\mu\text{-}SC_4H_4D\text{-}C,S)]^+$ (**III-*d*$_1$**) on the basis of NMR spectroscopic data. $^{1}H$ NMR (360 MHz, [$D_6$]-acetone, 25 °C): $\delta$ = 1.63 (br., $H_a$), 2.77 (br., $H_d$), 5.36 (br., $H_b$), 5.46 (br., $H_c$) ppm. $^{2}H$ NMR (77 MHz, $CDCl_3/CHCl_3$, 25 °C): $\delta$ = 1.58 (br., Da) ppm. $^{13}C$-DEPT NMR (91 MHz, [$D_6$]acetone, 25 °C): $\delta$ = 32.6 (C2), 42.7 (C5), 126.1 (C3), 137.1 (C4) ppm. NMR features corresponding to the dppp terminal ligands were coincident with those of **III**.

**Synthesis of [(dppp)$_2$Pt$_2$(μ-$SC_4H_5$)$_2$](BF$_4$)$_2$ (IV):** Aqueous $HBF_4$ (70 μL of 4 M solution, 0.28 mmol) was added to a solution of **II** (50 mg, 0.07 mmol) in $CH_3CN$ (10 mL). The mixture was stirred (15 min) and then evaporated to 5 mL under vacuum. Addition of diethyl ether gave a white precipitate, which was dissolved in ethyl acetate and purified on a neutral alumina column using the same solvent as eluent. Evaporation of the solvent afforded a white solid. Yield 47 mg, 84%. $^{1}H$ NMR (360 MHz, $CD_3CN$, 25 °C): $\delta$ = 4.75 (d, $^{3}J_{Ha,Hc}$ = 10, $^{2}J_{Ha,Hb} < 1$ Hz, $H_a$), 4.90 (d, $^{3}J_{Hb,Hc}$ = 16.5 Hz,

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

$H_b$), 5.34 (dt, $^3J_{Hc,Ha} = {}^3J_{Hc,Hd} = 10$, $^3J_{Hc,Hb} = 16$ Hz, $H_c$), 5.45 (d, $^3J_{He,Hd} = 10$ Hz, $H_e$), 5.74 (t, $^3J_{Hd,He} = {}^3J_{Hd,Hc} = 10$ Hz, $H_d$) ppm. $^{13}$C DEPT NMR (91 MHz, $CD_3CN$, 25 °C): $\delta$ = 136.6 (C4), 127.4 (C3), 120.8 (C2), 117.4 (C5) ppm. $^{31}P\{^1H\}$ NMR (146 MHz, $CD_3CN$, 25 °C): $\delta$ = –2.00 ($^1J_{Pt,P}$ = 2897.4 Hz) ppm. $^{19}$F NMR (235 MHz, [D$_6$]acetone, 25 °C): $\delta$ = –152.2 ppm. $^{195}Pt\{^1H\}$ NMR (77 MHz, $CD_3CN$, –20 °C): $\delta$ = –4415.8 ppm. $C_{62}H_{62}B_2F_8P_4Pt_2S_2$ (1558.94): calcd. C 47.77, H 4.01, S 4.11; found C 47.96, H 4.16, S 4.27. ESI MS (*m*/*z*): 693.5 (25%) corresponding to $[(dppp)_2Pt_2(SC_4H_5)_2]^{2+}$, and 1387.0 (100%) corresponding to $[(dppp)_2Pt_2(SC_4H_5)_2]^+$. IR: $\tilde{\nu}$ = 1051 i, br. ($BF_4$).

**Synthesis of $[(dppp)_2Pt_2(\mu\text{-}SC_4H_6)](BF_4)_2$ (V):** Aqueous $HBF_4$ (50 μL of 4 M solution, 0.20 mmol) was added to a solution of **III** (75 mg, 0.05 mmol) in degassed acetonitrile (10 mL) and the mixture stirred for 30 min. Then it was filtered through Celite, concentrated to 1–2 mL, and precipitated with addition of diethyl ether to yield a yellow solid. The solid was collected by filtration, washed with diethyl ether, and vacuum dried. Yield 65 mg, 82%. $^1$H NMR (360 MHz, [D$_6$]acetone, 25 °C): $\delta$ = 2.67 (br., 2$H_b$), 2.78 (br., 2$H_a$), 5.31 (dt, $^3J_{Hc,Hb} = 3.2$, $^3J_{Hc,Hd} = 9.2$ Hz, $H_c$), 5.90 (d, $^3J_{Hd,Hc} = 9.2$ Hz, $H_d$) ppm. $^{13}$C DEPT NMR (91 MHz, [D$_6$]acetone, 25 °C): $\delta$ = 26.8 (C2), 33.3 (C3), 119.7 (C5), 129.7 (C4) ppm. $^{31}P\{^1H\}$ NMR (146 MHz, [D$_6$]acetone, 25 °C): $\delta$ = 0.10 (d, $^1J_{Pt,P}$ = 2612.4 Hz), –0.92 ($^1J_{Pt,P}$ = 2965.3 Hz) ppm. $^{195}Pt\{^1H\}$ NMR (77 MHz, [D$_6$]-acetone, 25 °C): $\delta$ = –4675 (dd, $^1J_{P,Pt}$ = 2612 and 2966 Hz) ppm. $^{19}$F NMR (235 MHz, [D$_6$]acetone, 25 °C): $\delta$ = –152.2 ppm. ESI-MS: *m*/*z* = 650.3 (15%) and 1300.3 (100%) corresponding to $[(dppp)_2Pt_2(SC_4H_6)]^{2+}$ and $[(dppp)_2Pt_2(SC_4H_6)]^+$, respectively. $C_{58}H_{58}B_2F_8P_4Pt_2S$ (1474.80): calcd. C 47.23, H 3.96, S 2.17; found C 47.14, H 4.01, S 2.12. IR: $\tilde{\nu}$ = 1051 i, br. ($BF_4$).

The same reaction procedure but using only 1.2 equiv. of $HBF_4$ allowed separation of a yellow solid, whose acetone solution afforded adequate crystals for X-ray diffraction.

**Reaction of V with Bases (NaOMe, $Et_3N$):** A methanol solution of NaOMe (100 μL, 0.05 mmol) or $Et_3N$ (17.5 μL, 0.125 mmol) was added to a suspension of **V** (75 mg, 0.05 mmol) in $CH_3CN$ (10 mL). In both cases the resulting solution was stirred at room temperature for 30 min, after which time it was concentrated to dryness. Then, the solid was redissolved in benzene, filtered and precipitated by addition of diethyl ether. $^1$H and $^{31}$P NMR spectroscopic data of this solid in acetone solution evidenced the complete transformation of **V** into **III**.

**Reaction of II–V with HCl:** An excess of HCl was added to separate stirred $CH_2Cl_2$ (10 mL) solutions containing **II**, **III**, **IV**, or **V** (25 mg) in a 3–4:1 molar ratio at room temperature. The initial yellow-brown solution turned pale yellow and a white solid precipitated. After 30 min of stirring, the mixture was filtered and the soluble part analyzed by CG-MS. The solid was unequivocally identified as $[(dppp)PtCl_2]$ (65–80% yield) by NMR spectroscopy.[72,73] The solution was shown to be composed mainly of thiophene in the case of **II**, thiapentadiene or an isomer thereof ($C_4H_6S$) and thiophene[52] in a 4:1 molar ratio for **IV**, and a mixture of HS–$CH_2$–CH=CH–$CH_3$[74] and HS–$CH_2$–$CH_2$–CH=$CH_2$,[47] in 4:1 and 1:1 molar ratios, for **III** and **V**, respectively.

**Reaction of II–V with $NaBH_4$:** Solid $NaBH_4$ was made to react with separate stirred THF/$EtOH_{abs}$ solutions (10 mL) containing **II**, **III**, **IV**, or **V** (25 mg) in a 4:1 molar ratio at room temperature under a closed atmosphere. In the reactions involving **III**–**V**, formation of a black precipitate of $Ag_2S$ on a filter paper soaked with silver nitrate gave evidence of formation of $H_2S$. In all cases, after 20 h of stirring the initial yellow-brown solution became a dark-brown suspension. The black solid was separated and the solution analyzed by CG-MS. The solution was shown to contain thiophene in the case of **II**, but no thiols and/or organic volatiles were detected.

**X-ray Crystallographic Characterization:** A summary of crystal data, data collection, and refinement parameters for the structural analysis of complex $[(dppp)Pt(\mu\text{-}SC_4H_6)Pt(dppp)]_2(BF_4)_{2.95}(ClO_4)_{1.05}$ is given in Table 3. Measurements of diffraction intensity data were collected on a Bruker SMART CCD-1000 area-detector diffractometer with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). During the initial unit cell determination it was recognized that the crystal was twinned. Several crystals were assayed but all possessed the same diffraction pattern, so a small but diffracting crystal was chosen. The collected reflections were processed with the program CELLNOW,[75] which established two twin components with a ratio of 0.72/0.28. In order to process the twinned data, the absorption correction was applied using the multiscan TWINABS[75] program. Cell parameters were obtained from least-squares fit on the observed setting angles of all significant intensity reflections. A Patterson map solution of the structure to locate platinum atoms, followed by expansion of the structure with the program DIRDIF,[76] revealed all non-hydrogen atoms. The structure was resolved by direct methods and refined by full-matrix least-squares based on $F^2$, with the aid of SHELX-97[77] software. The thiolate ligand was modeled as two disordered $SCH_2CH_2CH{=}CH$ moieties with opposite orientations, finding a refined population ratio of 63/37 in one dinuclear complex and 69/31 in the other. All non-hydrogen atoms were anisotropically refined. All hydrogen atoms were included at geometrically calculated positions with thermal parameters derived from the parent atoms. Molecular graphics are represented by ORTEP-3 for Windows.

**Computational Details:** The calculations were performed with the Gaussian03 package,[78] using Density Functional Theory with the B3LYP functional.[79–81] For the Pt, P, and S atoms, the lanl2dz effective core potential was used to describe the inner electrons,[78,82,83] whereas their associated double-ζ basis set was employed for the remaining electrons. An extra series of d-polarization functions was also added for P (exp. 0.387) and S (exp. 0.503).[84] The three hydrides and the carbon atoms of thiophene were described by the 6-31G(d,p) basis set[85] and the remaining C and H atoms were described by the 6-31G basis set. The structures of the reactants, intermediates, transition states, and products were fully optimized in gas phase without any symmetry restriction. Frequency calculations were performed on all optimized structures, using the B3LYP functional, to characterize the stationary points as minima or TSs, as well as for the calculation of gas-phase Gibbs energies (*G*) at 298 K. Single-point solvent calculations were performed at optimized gas-phase geometries, using the CPCM approach,[86,87] which is an implementation of the conductor-like screening solvation model (COSMO) in Gaussian03.[88] Benzene, the solvent used in some experiments, was chosen as solvent (dielectric constant $\varepsilon = 2.247$). In this way $\Delta E_{benzene}$, resulting from adding the contribution of the Gibbs energy of solvation to the gas phase internal energies, were obtained.

**Supporting Information** (see also the footnote on the first page of this article): Comparison of the $^{31}P\{^{1}H\}$ NMR spectrum of **III** with its computed simulation. Table includes total energies and Cartesian coordinates of the optimized structures reported in the text.

## Acknowledgments

Financial support from the Spanish Ministerio de Educación y Ciencia (MEC) through Projects CTQ2004-01463 and CTQ2005-09000-C02-01 and from the Generalitat de Catalunya (GENCAT) through grant 2005SGR00896 is gratefully acknowledged. A. L. is indebted to GENCAT for a "Distinció per a la Promoció de la Recerca Universitària". We are grateful to Dr. T. Parella and Dr. J. Sola (UAB) for interesting discussions on NMR spectroscopic data, and to Dr. A. L. Llamas and Dr. B. Dacuña of the USC for crystal structure determination.

# Zeolite-Encapsulated Copper(II) Complexes of Pyridoxal-Based Tetradentate Ligands for the Oxidation of Styrene, Cyclohexene and Methyl Phenyl Sulfide

**Mannar R. Maurya,*[a] Baljit Singh,[a] Pedro Adão,[b] Fernando Avecilla,[c] and João Costa Pessoa[b]**

**Keywords:** Zeolites / Copper(II) complexes / Heterogeneous catalysis / Oxidation reactions

Interaction of copper(II)-exchanged zeolite-Y with *N*,*N*′-ethylenebis(pyridoxyliminato) ($H_2$pydx-en, **I**) and *N*,*N*′-propylenebis(pyridoxyliminato) ($H_2$pydx-1,3-pn, **II**) ligands in refluxing methanol leads to the formation of the corresponding complexes, abbreviated herein as [Cu(pydx-en)]-Y (**3**) and [Cu(pydx-1,3-pn)]-Y (**4**), in the supercages of zeolite-Y. The neat complexes, [Cu(pydx-en)] (**1**) and [Cu(pydx-1,3-pn)] (**2**), have also been prepared with these ligands. Spectroscopic studies (IR, UV/Vis and EPR), elemental analyses, thermal studies, field emission scanning electron micrographs (FE-SEM) and X-ray diffraction patterns have been used to characterise these complexes. The crystal and molecular structures of **1** and of **2**·$CH_3OH$, have been determined, confirming the ONNO binding mode of the ligands. The geometry around the metal ion is very slightly distorted square-planar in **1** and distorted square-pyramidal in **2**. The encapsulated complexes catalyse the oxidation, by $H_2O_2$ and *tert*-butyl hydroperoxide, of styrene, cyclohexene and thioanisole efficiently. Under optimised reaction conditions, the oxidation of styrene catalysed by **3** and **4** gave 23.6 % and 28.0 % conversion, respectively, using *tert*-butyl hydroperoxide as oxidant, where styrene oxide, benzaldehyde, benzoic acid and phenylacetaldehyde are the major products. Better conversions have been obtained using $H_2O_2$ as oxidant. Oxidation of cyclohexene catalysed by these complexes gave cyclohexene oxide, 2-cyclohexen-1-ol, cyclohexane-1,2-diol and 2-cyclohexen-1-one as the major products. A maximum of 90.1 % conversion of cyclohexene with **3** and 83.0 % with **4** was obtained under optimised conditions. Similarly, a maximum of 80.3 % conversion of methyl phenyl sulfide with **3** and 81.0 % with **4** was observed, where the selectivity of the major product methyl phenyl sulfoxide was found to be about 60 %. Tests for the recyclability and heterogeneity of the reactions have also been carried out, and the results indicate their recyclability. A possible reaction mechanism has been proposed by titrating a methanol solution of **1** and **2** with $H_2O_2$ to identify the possible intermediates.

## Introduction

Zeolites find applications in many scientific disciplines as catalysts and in all types of chemical engineering process technologies. The exchangeable property of extra-framework cations and suitable cavity size of the zeolites allow their modification by inclusion of chemically interesting molecules. A homogeneous catalyst, for example, a metal complex, may be considered one such interesting molecule and hence the term zeolite-encapsulated metal complexes. The large size of the encapsulated homogeneous catalysts and their rigidity make it difficult for them to escape the zeolite cages. Zeolite-encapsulated metal complexes having good catalytic activities possess the advantages of solid heterogeneous catalysts and share many of the advantageous features of homogeneous catalysts.

The flexible nature of salen-type [$H_2$salen = *N*,*N*′-bis(salicylidene)ethane-1,2-diamine] ligands has provided opportunities to design various transition-metal complexes in the nanocavity of zeolites and to develop catalytic processes for various reactions. Poltowicz et al. have encapsulated a whole range of metallosalen complexes {e.g., [Fe(salen)], [Mn(salen)], [Cu(salen)] and Co(salen)]} in zeolite-X to study their catalytic activity for the oxidation of cyclooctane.[1] Ratnasamy and co-workers have used copper(II) and manganese(III) complexes of salen derivatives encapsulated in the cavity of zeolite-X and zeolite-Y for the oxidation of styrene under aerobic conditions using *tert*-butyl hydroperoxide as an oxidant. The catalytic efficiency of these encapsulated complexes was much higher than that of the neat complexes. Electron-withdrawing substituents such as Cl, Br and $NO_2$ on the aromatic ring enhance the rate of oxidation.[2,3] These complexes also catalyse the oxidation of phenol and *p*-xylene.[4,5] Epoxidations of cyclohexene, cyclooctene, 1-hexene and other various types of alkenes, arenes and cycloalkenes, catalysed by different

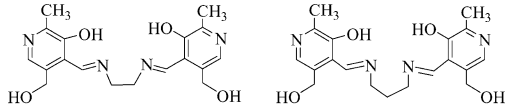
complexes of salen-type ligands, have also been carried out.[6–9] [Co(salophen)]-Y [$H_2$salophen = *N*,*N*′-bis(salicylidene)benzene-1,2-diamine] and related derivatives catalysed the oxidation of β-isophorone (βIP) to ketoisophorone (KIP) (along with other minor products) in the presence of an oxidant at ambient conditions of temperature and pressure.[10] Liquid-phase oxidation of phenol with $H_2O_2$ has been reported using copper(II) and oxidovanadium(IV) complexes of *N*,*N*′-bis(salicylidene)propane-1,3-diamine ($H_2$sal-1,3-pn) and *N*,*N*′-bis(salicylidene)diethylenetriamine ($H_2$saldien).[11–13] Copper(II) and oxidovanadium(IV) complexes of *N*,*N*′-bis(salicylidene)cyclohexane-1,2-diamine ($H_2$sal-dach) catalyse the oxidation of styrene, cyclohexene and cyclohexane efficiently.[14]

The catalytic potential of metal complexes encapsulated in the nanocavity of zeolites prompted us to design new zeolite-Y-encapsulated copper(II) complexes of tetradentate ligands **I** and **II** (Scheme 1). Catalytic potentials of these complexes have been demonstrated by studying the oxidation of styrene, cyclohexene and methyl phenyl sulfide. Copper(II), nickel(II) and oxidovanadium(IV) complexes of **I** have been reported previously.[15,16] The structure of [Ni(pydx-en)] has been confirmed by single-crystal X-ray diffraction,[17] while other complexes have been characterised by elemental analysis and spectroscopic techniques. We have also prepared neat copper(II) complexes of **I** and **II** to evaluate their catalytic potential and characterised them by single-crystal X-ray diffraction.

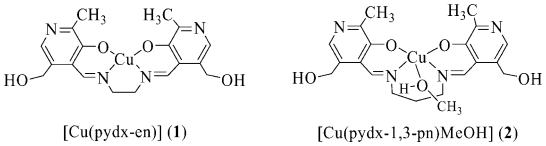


Scheme 1.

## Results and Discussion

### Synthesis and Characterisation of Catalysts

Scheme 2 presents the complexes prepared in this study. Their structures are based on elemental analysis and various spectroscopic studies, as well as on X-ray structure determinations. The presence of very strong peaks corresponding to $CuLH^+$ and $CuLNa^+$ in the ESI-MS spectra (positive mode) of DMSO solutions of **1** and **2**, with the correct isotope ratios, also confirms the integrity of the complexes in solution.



Scheme 2.

Reaction of cupric acetate with ligands $H_2$pydx-en (**I**) and $H_2$pydx-1,3-pn (**II**) in refluxing methanol yielded [Cu(pydx-en)] (**1**) and [Cu(pydx-1,3-pn)(MeOH)] (**2**), respectively. Complex **1** has previously been isolated by treating **I** with cupric acetate in aqueous solution.[16] Encapsulation of these complexes in the nanocavities of zeolite-Y involved the exchange of copper(II) ion with Na-Y in water followed by reaction of the metal-exchanged zeolite-Y with **I** or **II** in methanol. This method is referred to as the flexible ligand method. Here, the ligands enter into the cavity of zeolite-Y because of their flexible nature and interact with the metal ion to give [Cu(pydx-en)]-Y (**3**) and [Cu(pydx-1,3-pn)]-Y (**4**). Finally, extraction of impure samples with methanol using a Soxhlet extractor removed excess free ligand, and stirring in DMF removed neat metal complex formed on the surface of the zeolite, if any. As the crude mass was well extracted, the metal content found after encapsulation is only due to the presence of copper(II) complexes in the supercages of the zeolite-Y. The diagonal dimension of the complexes is about 12 Å {in [Cu(pydx-en)]} or about 11 Å {in [Cu(pydx-1,3-pn)(MeOH)]}, which suggests that they will fit nicely into the supercages of zeolite-Y. The molecular formulae of the encapsulated complexes are based on the respective neat complex. The Si/Al ratio of 9.67 of zeolite-Y taken here corresponds to a unit cell formula $Na_{18}(AlO_2)_{18}(SiO_2)_{174}$. The estimated number of copper atoms per unit cell is 2.5 for [Cu(pydx-en)]-Y (**3**) and 2.4 for [Cu(pydx-1,3-pn)]-Y (**4**).

### Structure Description of [Cu(pydx-en)] (1) and [Cu(pydx-1,3-pn)(MeOH)] (2)

Figures 1 and 2 include ORTEP representations of the molecular structure of [Cu(pydx-en)] (**1**) and [Cu(pydx-1,3-pn)(MeOH)] (**2**), respectively, and Table 1 provides selected bond lengths and angles of these compounds. The molecules are neutral, as both phenol groups are deprotonated, and the ligands coordinate to the Cu atom through two phenolate oxygen ($O^-_{phenolate}$) atoms and two imine nitrogen ($N_{imine}$) atoms. The geometry around the metal ion is slightly distorted square-planar in **1** and distorted square-pyramidal in **2**. A methanol molecule occupies the fifth coordination position in **2**.

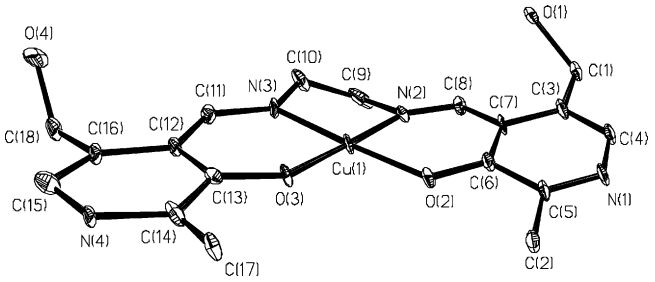


Figure 1. ORTEP diagram of [Cu(pydx-en)] (**1**) showing the atom-labelling scheme. The thermal ellipsoids were drawn at the 30% probability level.

The planar arrangement Cu(ONNO) is distorted, the *cis*/*trans* angles not being 90° and 180°. The *cis* angles are 90.0(3), 94.8(3), 91.2(3) and 84.1(3)° in **1**, and 82.08(4), 87.94(4), 92.29(4) and 97.76(4)° in **2**, and the *trans* angles are 175.2(3) and 178.8(2)° in **1**, and 169.92(4) and 166.61(4)° in **2**. The angles with the apical position of the O atom of the methanol molecule are 90.18(4), 94.46(5), 89.23(4) and 97.71(5)° in **2**.

In complex **1** the ligand forms a set of (6+5+6)-membered chelate rings, and the deviations from the planarity are listed in Table 1. The plane formed by the donor atoms N(2)–N(3)–O(2)–O(3) has a deviation from planarity of 0.0015(30) Å, and if the $Cu^{II}$ ion is included, 0.0037(30) Å. In complex **2** the ligand forms a set of (6+6+6)-membered chelate rings, and the deviations from planarity are also listed in Table 1. The basal plane of the square pyramid formed by N(2)–N(3)–O(2)–O(3) atoms has a deviation from planarity of 0.1063(05) Å, and the $Cu^{II}$ ion is 0.1020 Å above the plane. The Cu–O and Cu–N bond lengths (Table 1) are similar and in the usual range found for these compounds, 1.9–2.1 Å. The C–O distances are also typical for this type of ligands,[15–21] and the C=N bonds are double bonds, with distances of about 1.3 Å.

In complex **1** the $HO(CH_2)$ groups of the pyridoxal rings are in a *syn* position to each other, but in complex **2** the $HO(CH_2)$ groups of the pyridoxal rings are in an *anti* conformation, similar to other complexes with this type of ligand.[16] The pyridine nitrogen atoms and alcohol group of $HO(CH_2)$ of the pyridoxal rings are involved in intermolecular H bonds. In complex **2**, the OH groups of the coordinated methanol molecule are also involved in H bonds. The bond lengths and angles of the hydrogen bonds are also included in Table 1.

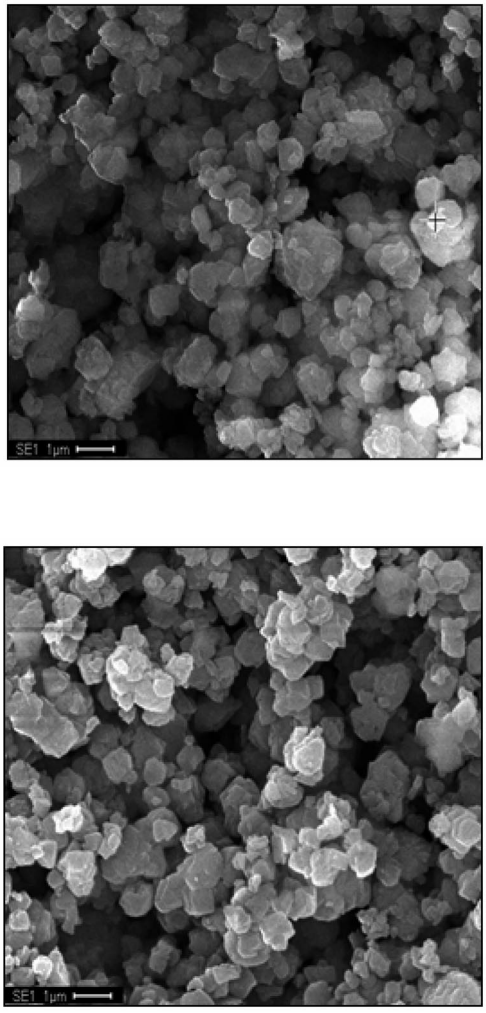

Figure 3. Field emission scanning electron micrograph of [Cu(pydx-en)]-Y (top) and [Cu(pydx-1,3-pn)]-Y (bottom).

## Field Emission Scanning Electron Micrograph and Energy Dispersive X-ray Analysis Studies

Figure 3 presents the field emission scanning electron micrographs of [Cu(pydx-en)]-Y and [Cu(pydx-1,3-pn)]-Y. It is clear from the micrographs that zeolite-entrapped copper complexes have well-defined crystals, and there is no indication of the presence of any metal ions or complexes on the surface. Energy-dispersive X-ray analysis plots support this conclusion as no copper or nitrogen contents were noted on the spotted surface in plots for both catalysts. The average silicon and aluminium percentage obtained on the spotted surfaces were about 30% and 10%, respectively. An amount of about 3% sodium suggests the exchange of remaining free copper ions by sodium ions during the re-exchange process (see Experimental Section). Only a small amount of carbon (about 5%) but no nitrogen suggests the presence of a trace amount of solvent (methanol) from which it was finally washed after Soxhlet extraction. No morphological changes on the surface upon encapsulation of the complexes in the cavity are seen because of their poor loading.

## Powder X-ray Diffraction Studies

The powder X-ray diffraction patterns of Na-Y, Cu-Y and encapsulated copper(II) complexes were recorded at $2\theta$ values between 5 and 50°, and some representative patterns are presented in Figure 4. Essentially similar diffraction

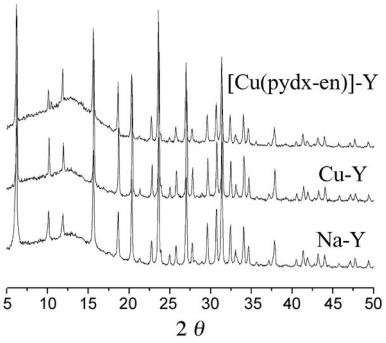

Figure 4. XRD patterns of Na-Y, Cu-Y and [Cu(pydx-en)]-Y (**3**).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

patterns were noticed in encapsulated complexes Cu-Y and Na-Y, except zeolite with encapsulated metal complexes has a slightly weaker intensity. These observations indicate that the framework of the zeolites do not suffer any significant structural changes during encapsulation, that is, crystallinity of the zeolite-Y is preserved.

### Thermogravimetric Analysis Studies

The decomposition of complexes **3** and **4** occurs in three overlapping steps. An endothermic loss of trapped water and methanol occurs between 80 and 200 °C, while exothermic removal of intra-zeolite water occurs between 300 and 350 °C. This is followed by endothermic loss of the ligand's residue, which continues until the removal of all organic mass at about 700 °C has occurred. The low percentage of weight loss (about 10%) for this last step indicates the presence of an only small amount of metal complexes in the cavities of the zeolite. This is in agreement with the low copper content estimated for these complexes. A weight loss of 6.9%, equivalent to methanol, in **2** occurs up to about 130 °C. The anhydrous complex is stable up to 260 °C, and then it decomposes in two major steps that are complete at 375 °C. The remaining residue of 18.1% slowly stabilises with the formation of a final residue of 17.5% (about 17.1% for CuO) at about 800 °C. A slightly different decomposition pattern has been obtained for **1**, where the decomposition of the stable complex starts at about 290 °C and occurs in two overlapping steps. The decomposition is complete at about 360 °C. The remaining residue of 20.6% further loses weight up to about 800 °C and stabilises at 18.3%. The calculated residue for CuO of 18.9% agrees with the value observed.

### IR Spectral Studies

A partial list of IR spectroscopic data is presented in Table 2. The intensity of the peaks in encapsulated complexes is, however, weak because of their low concentration in zeolite matrix; the spectra of the encapsulated as well as neat complexes showed essentially similar bands. Comparison of the spectra of these complexes with the respective ligand provides evidence for the coordinating mode of ligands in complexes. The ligand $H_2$pydx-en exhibits a medium-intensity band around 2700 $cm^{-1}$ due to intramolecular hydrogen bonding. Absence of this band in the spectra of encapsulated complexes indicates the destruction of the hydrogen bond followed by the coordination of the phenol oxygen atom after deprotonation. Existence of this band, however, in neat complexes hints towards the presence of hydrogen bonding. A sharp band appearing at 1626 $cm^{-1}$ (in **I**) or at 1632 $cm^{-1}$ (in **II**) due to the $\nu$(C=N) (azomethine) shifts to higher wavenumbers in complexes, thereby suggesting the coordination of the azomethine nitrogen atom. Several multiple bands of medium intensity covering the region 2850–3000 $cm^{-1}$ are observed due to C–H bands. The spectral patterns of these complexes are similar to [Cu(pydx-en)] reported in the literature.[16]

### UV/Vis Spectral Studies

UV/Vis spectral studies of **I** and its copper(II) complex **1** have been discussed in detail in the literature.[16] Other complexes reported here exhibit very similar spectral patterns. The well-defined band at 590 nm in **1** and a broad band covering the region 570–650 nm in **2** have been assigned to a d–d transition. Such a d–d band in zeolite-encapsulated complexes could not be obtained because of their poor loading, while ligand bands appearing in the UV region are similar to those observed for neat complexes. This data is collected in Table 2 and the spectra of encapsulated complexes are presented in Figure 5.

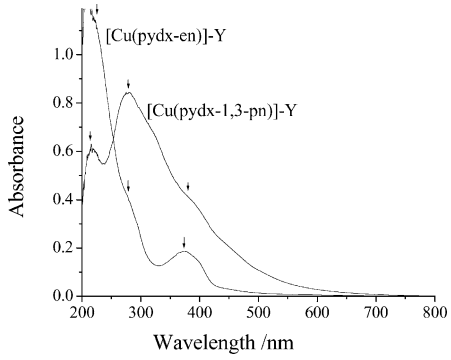

Figure 5. UV/Vis spectra of [Cu(pydx-en)]-Y and [Cu(pydx-1,3-pn)]-Y dispersed in nujol.

### EPR Studies

The EPR spectra of the neat $Cu^{II}$ complexes **1** and **2** in the polycrystalline state are broad because of dipolar and spin–spin exchange interactions. It is clear that they are characterised by an axial **g** tensor, but the hyperfine features

Table 2. IR and UV/Vis spectroscopic data of ligand, pure and encapsulated complexes.

| Compound | IR [$cm^{-1}$] | | UV/Vis | |
|---|---|---|---|---|
| | $\nu$(OH) | $\nu$(C=N) | Solvent | $\lambda_{max}$ [nm] |
| $H_2$pydx-en (**I**) | 3280–3450 | 1626 | $CH_3OH$ | 216, 252, 335 |
| $H_2$pydx-1,3-pn (**II**) | 2846–3480 | 1632 | $CH_3OH$ | 215, 252, 334 |
| [Cu(pydx-en)] (**1**) | ca. 3400 | 1634 | $CH_3OH$ | 235, 277, 378 |

were not resolved, neither at room temperature nor at 77 K, and not much structural information can be obtained. The EPR spectra of the neat $Cu^{II}$ complexes **1** and **2** in DMF solutions, and of the catalysts **3** and **4** are given in Figures 6 and 7.

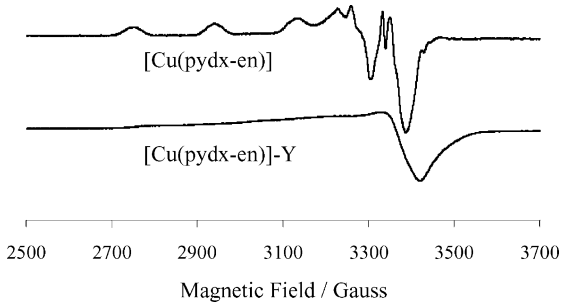

Figure 6. EPR spectra of a frozen DMF solution of [Cu(pydx-en)] (**1**) and of [Cu(pydx-en)]-Y (**3**) at room temperature.

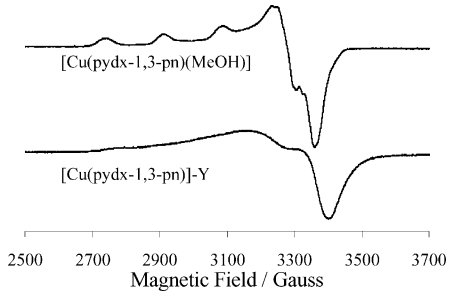

Figure 7. EPR spectra of a frozen DMF solution of [Cu(pydx-1,3-pn)(MeOH)] (**2**) and of [Cu(pydx-1,3-pn)]-Y (**4**) at room temperature.

The spectra of the encapsulated complexes **3** and **4** are reasonably resolved, indicating the encapsulation of individual molecules in the supercages of Na-Y. The intermolecular interactions are avoided because of isolation of the zeolite cavities, indicating that the $Cu^{II}$ sites are well separated in the catalyst, and thereby the spin Hamiltonian parameters can be estimated with reasonable accuracy; these are listed in Table 3.

Both neat complexes **1** and **2** have an $N_2O_2$ binding mode and are monomeric in the solid state. Complex **1** has a square-planar configuration, and **2** has square-planar configuration with a pyramidal distortion. In DMF solutions the representation of the $A_{\|}$, $g_{\|}$ values fit well with those of other [$Cu^{II}$(salen)] complexes.[5,22–25] The $g_{\|}/A_{\|}$ ratio is 112.7 for **1**, indicating a remarkable planarity of the square-planar geometry, as found in the solid state. For **2** this ratio is 126, but this is mainly due to a decrease in $A_{\|}$. Very similar $g_{\|}$ and $A_{\|}$ parameters and $g_{\|}/A_{\|}$ ratios were found for [$Cu^{II}$(salen)] (2.212, $203.7\times10^{-4}$ $cm^{-1}$, 109, respectively) and [$Cu^{II}$(sal-1,3-pn)] (2.254, $172.5\times10^{-4}$ $cm^{-1}$, 131, respectively),[25] in DMF solutions, indicating very similar geometries and balance of charge to those of **1** and **2**. No superhyperfine structure is distinguished.

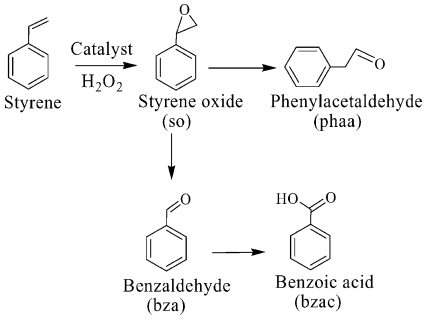
The EPR spectra of the encapsulated complexes were recorded at room temperature and are broader than those for frozen solutions, suggesting that the complexes located in the supercages may be present in more than one geometrical conformation. However, the $g_{\|}$ and $A_{\|}$ parameters and $g_{\|}/A_{\|}$ ratios ($g_{\|}/A_{\|}$ = 113 for **3** and 126 for **4**) almost coincide with those obtained in DMF solutions, indicating similar geometries and balance of charge for the complexes in the encapsulated and dissolved forms.

## Catalytic Activity Studies

The catalytic activities of the zeolite-encapsulated and neat complexes have been demonstrated by studying the oxidation of styrene, cyclohexene and methyl phenyl sulfide.

### *Oxidation of Styrene*

The oxidation of styrene, catalysed by [Cu(pydx-en)]-Y and [Cu(pydx-1,3-pn)]-Y, was carried out using $H_2O_2$ and *tert*-butyl hydroperoxide as oxidants to give styrene oxide, benzaldehyde, benzoic acid and phenylacetaldehyde (Scheme 3) along with minor amounts of unidentified products. Hulea and Dumitriu[26] have reported some of these products while using catalysts TS-1 and MCM-41. All oxidation products as observed here were identified recently using the polymer-anchored catalyst PS-[VO(sal-ohyba)-(DMF)] ($H_2$sal-ohyba = Schiff base derived from salicylaldehyde and *o*-hydroxybenzylamine)[27] and the zeolite-Y-encapsulated complex [VO(sal-dach)]-Y.[14]



Scheme 3.

Table 3. EPR data for [Cu(pydx-en)] and [Cu(pydx-1,3-pn)(MeOH)] complexes as neat and encapsulated in zeolite-Y.

| Complex | $g_{xx}$ | $g_{yy}$ | $g_{zz(\|)}$ | $A_{xx}$ ($\times10^4$ $cm^{-1}$) | $A_{yy}$ ($\times10^4$ $cm^{-1}$) | $A_{zz(\|)}$ ($\times10^4$ $cm^{-1}$) |

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

In order to achieve the maximum oxidation of styrene, catalyst **3** was taken as a representative, and the effect of four different reaction parameters – viz. the amount of $H_2O_2$ (mol of $H_2O_2$ per mol of styrene), amount of catalyst, volume of solvent and temperature of the reaction – was studied.

Three different aqueous 30% $H_2O_2$/styrene molar ratios of 1:1, 2:1 and 3:1 were considered while keeping the fixed amount of styrene (1.04 g, 10 mmol) and catalyst (0.025 g) in $CH_3CN$ (20 mL) at 80 °C. The periodic analyses of results up to 6 h are illustrated in Figure 8. Increasing the $H_2O_2$/styrene ratio from 1:1 to 2:1 improved the conversion from 9.1% to 14.8% while a 3:1 ratio showed a further increment of conversion of hardly 1%. Therefore, it is clear that the 2:1 molar ratio is quite suitable to obtain the optimum styrene conversion of 14.8% in the 6 h reaction time.

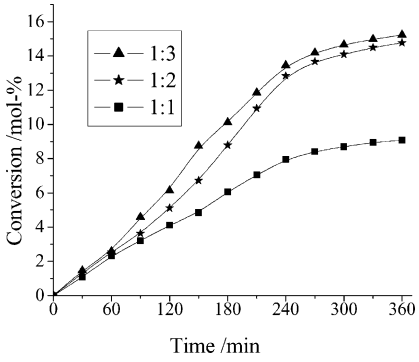

Figure 8. Effect of $H_2O_2$ on the oxidation of styrene. Reaction conditions: styrene (1.04 g, 10 mmol), [Cu(pydx-en)]-Y (**3**) (0.025 g), $CH_3CN$ (20 mL) and temp. (80 °C).

Similarly, for three different amounts – viz. 0.015, 0.025 and 0.035 g – of [Cu(pydx-en)]-Y at a styrene/aqueous 30% $H_2O_2$ ratio of 1:2 under the above reaction conditions, 0.015 g of catalyst, achieved only 7.8% conversion, whereas 0.025 g of catalyst gave a maximum conversion of 14.8% in 6 h of reaction time. A further increment of catalyst (0.035 g) has shown no improvement (Figure 9). The reason for reduced activity at higher catalyst dose may be adsorption/chemisorption of the two reactants on separate catalyst particles, thereby reducing the chance to interact.

Figure 10 illustrates the oxidation of styrene at three different temperatures – viz. 60, 70 and 80 °C –, while keeping the optimised conditions of 10 mmol of styrene, 20 mmol of $H_2O_2$ and 0.025 g of catalyst in 20 mL of acetonitrile. It is evident from the figure that the performance of the catalyst is poor at 60 °C wherein only 3.9% conversion was observed. Increasing the reaction temperatures to 70 and 80 °C increases the conversion to 7.0% and 14.8%, respectively. Thus, conducting the catalytic reaction at 80 °C is most suitable to maximise the oxidation of styrene. We have also observed that reducing the volume of $CH_3CN$ to 10 mL under the above optimised reaction conditions improved the conversion considerably, and two more components, though in poor yield, have also been obtained.

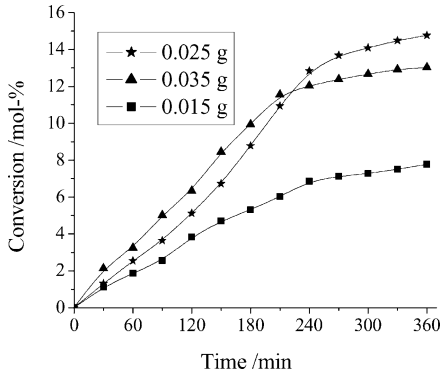

Figure 9. Effect of the amount of catalyst on the oxidation of styrene. Reaction conditions: styrene (1.04 g, 10 mmol), 30% $H_2O_2$ (2.27 g, 20 mmol), $CH_3CN$ (20 mL) and temp. (80 °C).

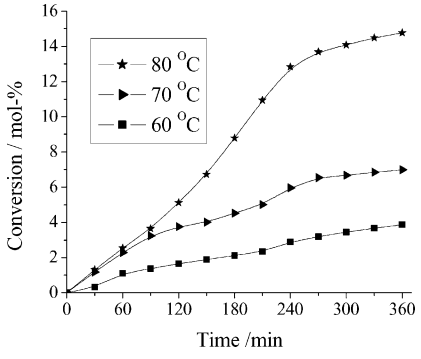

Figure 10. Effect of the temperature on the oxidation of styrene. Reaction conditions: styrene (1.04 g, 10 mmol), [Cu(pydx-en)]-Y (0.025 g), 30% $H_2O_2$ (2.27 g, 20 mmol) and $CH_3CN$ (20 mL).

Thus, for the maximum oxidation of 10 mmol of styrene, the other required conditions as concluded were: [Cu(pydx-en)]-Y (0.025 g), $H_2O_2$ (2.27 g, 20 mmol), $CH_3CN$ (10 mL) and temperature (80 °C). Under these optimised reaction conditions, the catalytic activities of **1**–**4** were further tested, and the results obtained are shown in Figure 11. Table 4 compares the selectivity of the various products obtained after 6 h of reaction time, along with the percent conversion of styrene and turnover frequency. It is clear from Table 4 and Figure 11 that [Cu(pydx-1,3-pn)]-Y exhibits 37.4% conversion, which is better than that exhibited by [Cu(pydx-en)]-Y (33.3%). Both catalysts gave mainly four products: styrene oxide, benzaldehyde, phenylacetaldehyde and benzoic acid. The selectivity for benzaldehyde is much higher, while the other products are obtained in small amounts.

We have also tested the catalytic activity of the neat complexes **1** and **2** for the oxidation of styrene using an equimolar concentration of metal ion as in their respective zeolite-encapsulated metal complex. Figure 11 also provides the conversion as a function of time, while Table 4 lists all other details. Thus, under the above reaction conditions, the conversion obtained by the neat complexes (18.7% for **1** and 22.3% for **2**) is significantly lower than that shown by the respective encapsulated complexes. Again, all four products have been obtained with the selectivity order: benzaldehyde > styrene oxide > phenylacetaldehyde > benzoic acid.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

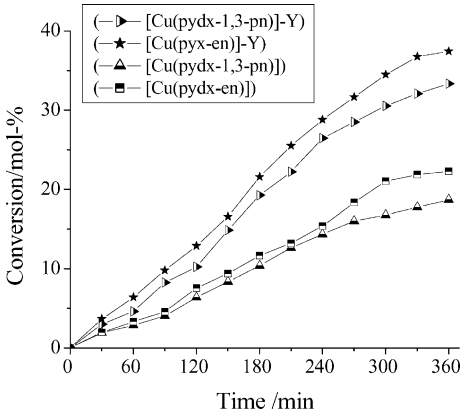

Figure 11. Catalytic comparison of zeolite-encapsulated and neat complexes for the oxidation of styrene in the presence of $H_2O_2$ as oxidant. Reaction conditions: styrene (1.04 g, 10 mmol), catalyst (0.025 g for encapsulated and 0.00133 g in the case of neat complexes), $H_2O_2$ (2.27 g, 20 mmol), $CH_3CN$ (10 mL) and temp. (80 °C).

Table 4. Product selectivity and percent conversion of styrene after 6 h of reaction time with $H_2O_2$ as oxidant.

| Catalyst ($H_2O_2$) | Conv. (%) | Product selectivity (%) | | | | | TOF[a] [$h^{-1}$] |
|---|---|---|---|---|---|---|---|
| | | | | | Others | | |
| [Cu(pydx-en)]-Y (**3**) | 33.3 | 82.2 | 12.4 | 1.6 | 1.4 | 2.4 | 179 |
| [Cu(pydx-1,3-pn)]-Y (**4**) | 37.4 | 75.4 | 15.0 | 4.0 | 3.0 | 2.6 | 215 |
| [Cu(pydx-en)] (**1**) | 18.7 | 81.6 | 7.4 | 4.8 | 2.6 | 3.6 | 106 |
| [Cu(pydx-1,3-pn)(MeOH)] (**2**) | 22.3 | 79.4 | 9.9 | 6.2 | 3.0 | 1.5 | 128 |

[a] TOF [$h^{-1}$] (turnover frequency): mol of substrate converted per mol of metal (in the solid catalyst) per hour.

Under the above optimised reaction conditions, the catalytic action of neat as well encapsulated complexes has also been tested using *tert*-butyl hydroperoxide (TBHP) as an oxidant: 70% TBHP (2.57 g, 20 mmol), catalyst (0.025 g for encapsulated and 0.00133 g, for neat complexes) and styrene (1.04 g, 10 mmol) were used in $CH_3CN$ (20 mL), and the reaction was carried out at 80 °C. Figure 12 shows the conversion as a function of time, and Table 5 compares the selectivity data along with the conversion and turnover frequency after 6 h of reaction time. It is clear that the obtained percentage conversion varies in the range 13.6–28.0% with the order: [Cu(pydx-1,3-pn)]-Y (28.0%) > [Cu(pydx-en)]-Y (23.6%) > [Cu(pydx-1,3-pn)] (16.2%) > [Cu(pydx-en)] (13.6%). Thus, the overall conversion of styrene with TBHP is always lower than with $H_2O_2$. The selectivity of the formation of an important component – styrene oxide – is better (43.4–70.5%), but two more products, namely benzoic acid and phenylacetaldehyde, have also been obtained.

The highest yield of benzaldehyde using $H_2O_2$ as oxidant is possibly due to further oxidation of styrene oxide formed in the first step by a nucleophilic attack of $H_2O_2$ on styrene oxide followed by cleavage of the intermediate hydroperoxystyrene.[28] The formation of benzaldehyde may also be facilitated by the direct oxidative cleavage of the styrene side-chain double bond by a radical mechanism.[27] Formation of other products such as phenylacetaldehyde is possible through isomerisation of styrene oxide, while the formation of benzoic acid from benzaldehyde is straightforward.

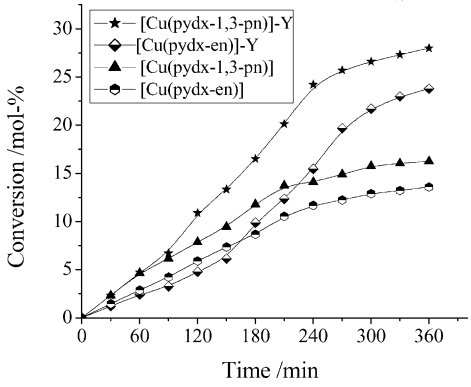

Figure 12. Catalytic comparison of zeolite-encapsulated metal complexes and neat complexes for the oxidation of styrene in the presence of TBHP as oxidant. Reaction conditions: styrene (1.04 g, 10 mmol), catalyst (0.025 g for encapsulated and 0.00133 g in case of neat complexes), TBHP (2.57 g, 20 mmol), $CH_3CN$ (20 mL) and temp. (80 °C).

Table 5. Product selectivity and percent conversion of styrene with TBHP after 6 h of reaction time.

| Catalyst (TBHP) | Conv. (%) | Product selectivity (%) | | | | | TOF [$h^{-1}$] |

### *Oxidation of Cyclohexene*

The oxidation of cyclohexene catalysed by encapsulated complexes gave cyclohexene oxide, 2-cyclohexen-1-ol, cyclohexane-1,2-diol and 2-cyclohexen-1-one, as shown in Scheme 4. Recently, we observed all these products while using catalyst [VO(sal-dach)] encapsulated in zeolite-Y.[14]

The reaction conditions have been optimised considering **3** as a representative catalyst and varying the amount of catalyst, oxidant, solvent and temperature of the reaction mixture. The effect of $H_2O_2$ concentration on the oxidation of cyclohexene is shown in Figure 13. Three different $H_2O_2$/cyclohexene molar ratios of 1:1, 2:1 and 3:1 were used at a fixed amount of cyclohexene (0.82 g, 10 mmol), catalyst (0.025 g), acetonitrile (20 mL) and temperature (75 °C). From Figure 13 it is clear that a 3:1 molar ratio is the best of those tested, to obtain a conversion of 38.8% in 6 h.

The amount of catalyst has shown considerable affect on the oxidation of cyclohexene. For a cyclohexene/$H_2O_2$ ratio of 1:3, five different amounts of catalyst – viz. 0.015, 0.025, 0.035, 0.050 and 0.065 g – were used under the above reaction conditions, and the results obtained are summarised in Figure 14. The conversion increases with an increase in the amount of catalyst from 0.015 to 0.050 g (28 to 56.2%), and

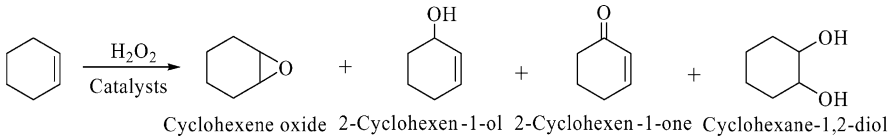

Scheme 4.

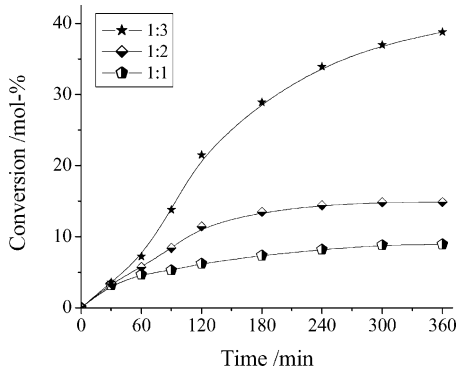

Figure 13. Effect of $H_2O_2$ on the oxidation of cyclohexene. Reaction conditions: cyclohexene (0.82 g, 10 mmol), [Cu(pydx-en)]-Y (0.025 g), $CH_3CN$ (20 mL) and temp. (75 °C).

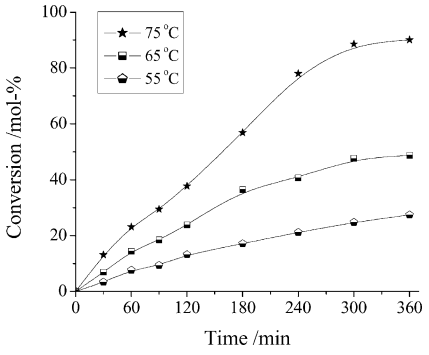

Figure 15. Effect of the temperature on the oxidation of cyclohexene. Reaction conditions: cyclohexene (0.82 g, 10 mmol), [Cu(pydx-en)]-Y (**3**) (0.050 g), 30% $H_2O_2$ (3.40 g, 30 mmol) and $CH_3CN$ (10 mL).

then assumes a lower trend with 0.065 g of catalyst (52.4%). Thus, an amount of 0.050 g of catalyst is considered adequate to carry out the oxidation of cyclohexene. It was also noted that by reducing the volume of acetonitrile to 10 mL, this conversion reached 90.1% with 0.050 g of catalyst under the above reaction conditions.

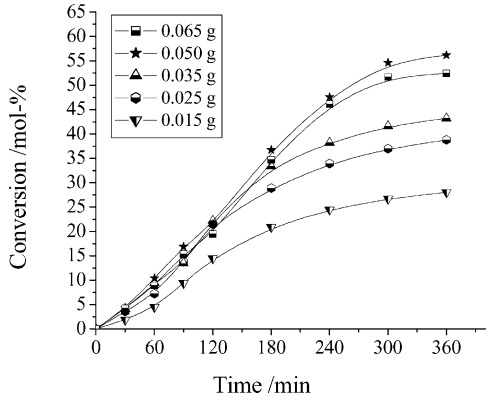

Figure 14. Effect of the amount catalyst on the oxidation of cyclohexene. Reaction conditions: cyclohexene (0.82 g, 10 mmol), 30% $H_2O_2$ (3.40 g, 30 mmol), $CH_3CN$ (20 mL) and temp.(75 °C).

Figure 15 illustrates the effect of temperature of the reaction medium on the conversion of cyclohexene as a function of time. Amongst the three different temperatures (55, 65 and 75 °C) for the fixed amount of cyclohexene (0.82 g, 10 mmol), aqueous 30% $H_2O_2$ (3.40 g, 30 mmol) and catalyst (0.050 g) in acetonitrile (10 mL), running the reaction at 75 °C has shown the best result, where 90.1% conversion has been obtained.

Thus, suitable reaction conditions for the maximum oxidation of cyclohexene were optimised as follows: cyclohexene (0.82 g, 10 mmol), $H_2O_2$ (3.40 g, 30 mmol), catalyst (0.050 g), acetonitrile (10 mL) and a temperature of 75 °C. Catalyst **4** was also tested under the above reaction conditions, and results along with the selectivity of various reaction products are summarised in Table 6. A maximum of 83.0% conversion has been achieved with **4**, which is less than that obtained by **3** (90.1%) in 6 h of contact time. However, both catalysts show the highest selectivity towards the formation of 2-cyclohexen-1-ol, which is followed by cyclohexene oxide. The selectivity of the two other products, 2-cyclohexen-1-one and cyclohexane-1,2-diol, has no definite trend.

We have also tested the catalytic activities of encapsulated complexes using *tert*-butyl hydroperoxide as an oxidant. Thus, catalyst (0.050 g), *tert*-butyl hydroperoxide (3.855 g, 30 mmol) and cyclohexene (0.82 g, 10 mmol) were used in acetonitrile (10 mL), and the reaction was carried out at 75 °C. The data, also presented in Table 6, show a poor conversion of cyclohexene (19.5% for **3** and 17.8% for **4**) with *tert*-butyl hydroperoxide in 6 h of contact time. Here, the major product obtained is cyclohexane-1,2-diol, while amounts of the other three products are very poor.

The neat complexes gave 45.5% (with 0.0028 g of **1**) or 50.7% (with 0.0027 g of **2**) conversion using $H_2O_2$ as an oxidant (Table 6). Here, the selectivity of cyclohexene oxide is better (33 to 38.7%) in comparison with the encapsulated complexes, although the overall selectivity orders of all products are the same. However, the turnover rates for encapsulated complexes, their stability towards decomposition and easy recovery from the reaction mixture make encapsulated complexes better catalysts than neat ones.

Table 6. Oxidation of cyclohexene and product selectivity using various catalysts.

| Catalyst | Oxidant | Conv. (%) | Product selectivity (%) | | | | | TOF [$h^{-1}$] |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | Other | |
| [Cu(pydx-en)]-Y (**3**) | $H_2O_2$ | 90.1 | 26.9 | 37.8 | 22.2 | 9.5 | 3.6 | 241 |
| | TBHP | 19.5 | 1.4 | 2.4 | 2.5 | 92.9 | 0.8 | 52 |
| [Cu(pydx-1,3-pn)]-Y (**4**) | $H_2O_2$ | 83.0 | 37.1 | 51.1 | 3.5 | 8.3 | 0.0 | 237 |
| | TBHP | 17.8 | 1.5 | 2.0 | 3.1 | 92.5 | 0.9 | 51 |
| [Cu(pydx-en)] (**1**) | $H_2O_2$ | 50.7 | 38.7 | 44.5 | 4.9 | 5.4 | 6.5 | 136 |
| [Cu(pydx-1,3-pn)(MeOH)] (**2**) | $H_2O_2$ | 45.5 | 33.0 | 51.5 | 5.0 | 4.9 | 5.6 | 130 |

The conversion of cyclohexene and selectivity of different reaction products using [Cu(pydx-1,3-pn)]-Y as catalyst under the optimised reaction conditions have been analysed as a function of time and are presented in Figure 16. It is clear from the plot that a selectivity of 20.7% of cyclohexene oxide and 35.5% of cyclohexen-1-ol has been obtained at a conversion of 20.2% of cyclohexene in 1 h of reaction time. The selectivity for these products increases with time and reaches 37.1% and 51.1%, respectively, with the increase of the conversion of cyclohexene to 83.0% in 6 h. The other two products, 2-cyclohexen-1-one and cyclohexane-1,2-diol, have 26.8% and 14.7% selectivity in the first hour, but their selectivities decrease with time and reach 3.5 and 8.2%, respectively. Thus, to obtain a good selectivity for the important product cyclohexene oxide, it is essential to run the reaction for at least 6 h under the optimised reaction conditions. After 6 h, only minor changes have been noted in the selectivities of the different reaction products.

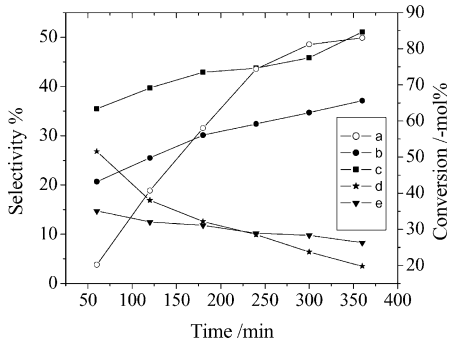

Figure 16. Conversion of cyclohexene and variation in the selectivity of various products as a function of time: (a) conversion of cyclohexene, (b) cyclohexene oxide, (c) 2-cyclohexen-1-ol, (d) 2-cyclohexen-1-one and (e) cyclohexane-1,2-diol.

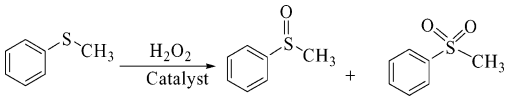
### *Oxidation of Methyl Phenyl Sulfide (Thioanisol)*

Enzyme sulfoxidases[29] facilitate sulfide peroxidase activity where the electron-rich sulfur atom of the sulfide undergoes electrophilic oxidation by $H_2O_2$ to give the sulfoxide and, further, sulfone. Such oxidation of methyl phenyl sulfide was tested with the copper complexes prepared in this work. Oxidation of methyl phenyl sulfide in the presence of $H_2O_2$ gave two products, namely methyl phenyl sulfoxide and methyl phenyl sulfone, as shown in Scheme 5.



Scheme 5.

The catalytic potential of these catalysts has also been optimised considering the amount of oxidant, solvent and catalyst. Thus, catalyst **4** was taken as a representative, and the amount of oxidant was varied at a fixed amount of methyl phenyl sulfide (1.242 g, 10 mmol) and catalyst (0.025 g) in acetonitrile (10 mL), and the reaction was carried out at ambient temperature. At an aqueous $H_2O_2$/substrate ratio of 2:1, a maximum of 69.3% conversion was achieved in 3 h of reaction time. Decreasing this ratio to 1:1 decreases the conversion of methyl phenyl sulfide considerably, while increasing this ratio to 3:1 has a marginal effect on the conversion (Figure 17). The only significant influence when using a 3:1 ratio is the completion of the reaction in less time. Increasing the volume of solvent to 20 mL under the above reaction conditions decreases the conversion considerably (to 64.3%).

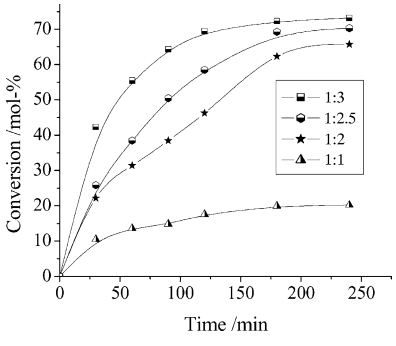


Figure 17. Effect of the amount of $H_2O_2$ on the oxidation of methyl phenyl sulfide as a function of time. Reaction conditions: methyl phenyl sulfide (1.242 g, 10 mmol), [Cu(pydx-1,3-pn)]-Y (0.025 g) and acetonitrile (10 mL).

Similarly, four different amounts of catalyst – viz. 0.015, 0.025, 0.035 and 0.050 g – were considered, while keeping methyl phenyl sulfide (1.242 g, 10 mmol) and 30% $H_2O_2$ (2.27 g, 20 mmol) in acetonitrile (10 mL). As mentioned in Figure 18, increasing the catalyst amount from 0.015 to 0.025 g increases the conversion from 46.8 to 69.3%. Increasing it to 0.035 g improves the conversion to 81.0%, while 0.050 g shows no improvement. Therefore, it is clear

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

that 0.035 g of catalyst is adequate to obtain an optimum methyl phenyl sulfide conversion of 81.0% in 3 h of contact time.

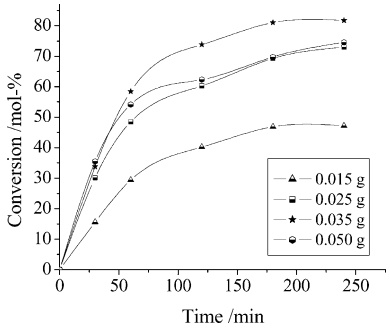

Figure 18. Effect of the amount of catalyst on the oxidation of methyl phenyl sulfide. Reaction conditions: methyl phenyl sulfide (1.242 g, 10 mmol), $H_2O_2$ (2.27 g, 20 mmol) and acetonitrile (10 mL).

Thus, under the optimised reaction conditions, that is, catalyst (0.035 g), methyl phenyl sulfide (1.242 g, 10 mmol), 30% $H_2O_2$ (2.27, 20 mmol) and acetonitrile (10 mL), catalyst **3** was also tested, and the results of both catalysts are compared in Figure 19, while Table 7 provides selectivity details. Under the optimised reaction conditions, **3** and **4** gave 80.3% and 81.0% conversion, respectively. In terms of the product selectivity, the selectivities of methyl phenyl sulfoxide and methyl phenyl sulfone are 63.3 and 36.7%, respectively, for **3** and 53.6 and 46.4%, respectively, for **4**. A blank reaction under similar conditions, that is, methyl phenyl sulfide (1.242 g, 10 mmol), aqueous 30% $H_2O_2$ (2.27 g, 20 mmol) and acetonitrile (10 mL), resulted in 35.2% conversion with 68.3% selectivity towards sulfoxide and 31.7% sulfone. Thus, catalysts **3** and **4** only enhanced the percent conversion of methyl phenyl sulfide and played no positive role in enhancing the selectivity of sulfoxide. In contrast, a positive role in enhancing the selectivity towards the formation of sulfoxide as well as conversion of methyl phenyl sulfide has been observed by oxidovanadium(IV) and copper(II) complexes encapsulated in the cavities of zeolite-Y.[30] The neat complexes also exhibited a good catalytic activity (68.4–69.9% conversion) when 0.0019 g amounts were used under the above optimised conditions. However, the selectivity for sulfone was better than for sulfoxide.

Catalytic activities of these complexes have also been tested using TBHP as an oxidant under similar conditions. Again, 0.035 g of catalyst has shown the best results at a fixed amount of methyl phenyl sulfide (10 mmol) and TBHP (20 mmol) in acetonitrile (10 mL). A maximum of 47.1% conversion has been obtained with **3**, while **4** gave only 18.1% conversion in 3 h of reaction time (Figure 20). Neat complexes **1** and **2** exhibited very poor conversion of 4.7 and 4.2%, respectively. Independently of the catalytic systems and conversions, the sulfoxide has been obtained selectively with TBHP.

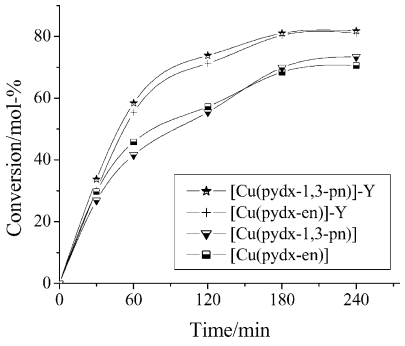

Figure 19. Oxidation of methyl phenyl sulfide by various catalysts using $H_2O_2$ as an oxidant.

Table 7. Conversion percentage of methyl phenyl sulfide in 3 h using $H_2O_2$ as an oxidant and selectivity of sulfoxide and sulfone.

### Test for Recyclability and Heterogeneity of the Reactions

The recyclability of both the encapsulated complexes has been tested in all three catalytic reactions. In a typical experiment, for example, for styrene, after a contact time of 6 h, the reaction mixture was filtered, and after activating the catalyst by washing with acetonitrile and drying at 120 °C, it was subjected to a further catalytic reaction under similar conditions. No appreciable loss in catalytic activity suggests that the complex is still present in the cavity of zeolite-Y. The filtrate collected after separating the used catalyst was placed in the reaction flask and the reaction was continued after adding fresh oxidant for another 4 h. The gas chromatographic analysis showed no improvement in conversion, and this confirms that the reaction did not proceed upon removal of the solid catalyst. The reaction was, therefore, heterogeneous in nature.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

### Possible Reaction Pathway of the Catalysts

In order to better understand the reaction mechanism, the neat complexes were treated with $H_2O_2$ and the progress of the reaction was monitored by electronic absorption spectroscopy. Thus, titration of a solution of **1** (about $10^{-4}$ M) in methanol with one-drop portions of 30% $H_2O_2$ dissolved in methanol resulted in the spectral changes shown in Figure 21. The intensity of the band at 378 nm changes marginally, but the band at 277 nm increases considerably, while the band at 235 nm (not shown) continuously gains intensity. With a more concentrated solution (about $10^{-3}$ M) now dissolving complex **1** in DMSO, upon equivalent $H_2O_2$ additions the band appearing at 590 nm broadens with an increase in the intensity (Figure 21, inset). A very similar spectral pattern has also been observed for **2** (Figure 22). The data suggest the interaction of copper(II) complexes with $H_2O_2$.

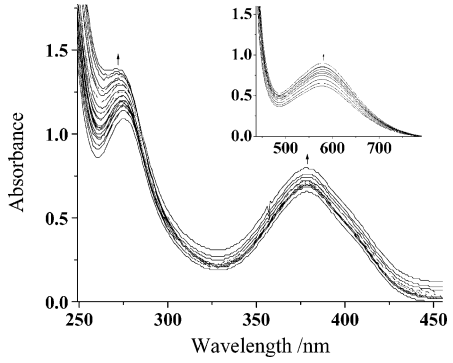

Figure 21. Titration of a methanol solution (about $10^{-4}$ M) of [Cu(pydx-en)] (**1**) with aqueous 30% $H_2O_2$ dissolved in methanol. The inset displays equivalent titrations, but with higher concentrations of **1** (about $10^{-3}$ M) dissolved in DMSO.

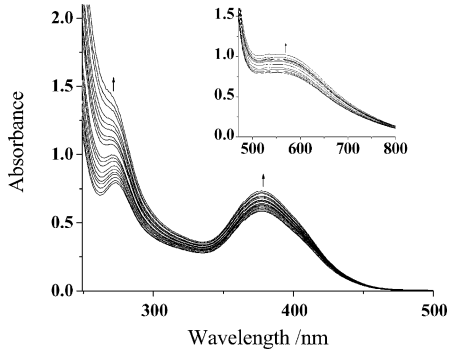

Figure 22. Titration of a methanol solution (about $10^{-4}$ M) of [Cu(pydx-1,3-pn)MeOH] (**2**) with aqueous 30% $H_2O_2$ dissolved in methanol. The inset displays equivalent titrations, but with higher concentrations of **2** (about $10^{-3}$ M) dissolved in DMSO.

At least three types of intermediates having a copper–oxygen interaction – side-on $Cu^{III}$–(μ-$\eta^2$-peroxido)–$Cu^{III}$, bis(μ-oxido–$Cu^{III}$) and $Cu^{III}$–O–O–H (copper hydroperoxide) – have been discussed in the literature during the catalytic action.[31,32] As copper complexes [Cu(pydx-en)] and [Cu(pydx-1,3-pn)] are monomeric in the cavity of zeolite, the facile formation of intermediates [(HOO)-Cu(pydx-en)] and [(HOO)-Cu(pydx-1,3-pn)], respectively, are expected because of the vacant available site in them (for example complex **3** was characterised in the solid state with a coordinated methanol molecule). This intermediate is expected to transfer the oxygen atoms to the substrates to obtain the products. Thus, the catalytic performance of the supported catalyst could be attributed to the facile formation of this Cu hydroperoxide intermediate species. The broadening of the band at about 590 nm indicates the merging of the d–d band with this charge-transfer band because of Cu hydroperoxide complex formation. In fact characteristic charge-transfer bands because of Cu hydroperoxide coordination are known to appear around 590 nm.[33]

Attempts to detect Cu hydroperoxide intermediates by ESI-MS (in the positive and negative modes) failed. The addition of $H_2O_2$ only increased the intensities of the peaks corresponding to $CuLH^+$ and $CuLNa^+$ (and $CuL{\cdot}2H^{2+}$ for larger amounts of $H_2O_2$) in the positive mode, but no peaks could be found in the negative mode that we could assign to Cu hydroperoxide intermediate species.

## Conclusions

Zeolite-Y-encapsulated copper(II) complexes [Cu(pydx-en)]-Y and [Cu(pydx-1,3-pn)]-Y with *N*,*N*′-ethylenebis(pyridoxyliminato) ($H_2$pydx-en) and *N*,*N*′-propylenebis(pyridoxyliminato) ($H_2$pydx-1,3-pn) ligands have been prepared. Neat complexes, [Cu(pydx-en)] and [Cu(pydx-1,3-pn)(MeOH)], have also been prepared with these ligands and characterised, and their crystal and molecular structures were determined, confirming the ONNO binding mode of the ligands. The encapsulated complexes catalyse the oxidation of styrene, cyclohexene and thioanisole efficiently, either using $H_2O_2$ or *tert*-butyl hydroperoxide as oxidants. Oxidation of styrene catalysed by [Cu(pydx-en)]-Y and [Cu(pydx-1,3-pn)]-Y gave 23.6% and 28.0% conversion, respectively, using TBHP as an oxidant. Using $H_2O_2$ as oxidant the major products were styrene oxide and benzaldehyde, while TBHP gave styrene oxide, benzaldehyde, benzoic acid and phenylacetaldehyde. Under the optimised conditions the maximum conversions obtained were 90.1% of cyclohexene, using [Cu(pydx-en)]-Y, and 83.0% using [Cu(pydx-1,3-pn)]-Y as catalyst; the major products identified were cyclohexene oxide, 2-cyclohexen-1-ol, cyclohexane-1,2-diol and 2-cyclohexen-1-one. Similarly, maximums of 80.3% conversion of methyl phenyl sulfide with [Cu(pydx-en)]-Y and of 81.0% with [Cu(pydx-1,3-pn)]-Y were observed, where the selectivity for the major product methyl phenyl sulfoxide was found to be about 60%. Tests for recyclability and heterogeneity of the reactions indicated their good recyclability. Of the alternative suggested mechanisms for catalysis, namely regarding the intermediates specifying the copper–oxygen interaction, our data suggest the involvement of $Cu^{III}$–O–O–H (copper hydroperoxide) intermediates.

## Experimental Section

**Materials:** Analytical reagent-grade pyridoxal hydrochloride (Hpydx·HCl, Himedia, Mumbai, India), methyl phenyl sulfide (Alfa Aeaser, USA), styrene, cyclohexene (Acros Organics, NJ, USA), cupric nitrate (E. Merck, Mumbai, India) and 30% aqueous $H_2O_2$ (Qualigens, Mumbai, India) were used as obtained. Y-zeolite (Si/Al = 10) was obtained from Indian Oil Corporation (R&D), Faridabad, India. All other chemicals and solvents used were of AR grade. Ligands $H_2$pydx-en (**I**) and $H_2$pydx-1,2-pn (**II**) were prepared as described in the literature.[15]

**Physical Methods and Analysis:** The copper content was measured using an inductively coupled plasma spectrometer (ICP; Labtam 8440 Plasmalab) after leaching the metal ions with conc. nitric acid and diluting with double-distilled water to specific volumes. IR spectra were recorded as KBr pellets with a Nicolet NEXUS Aligent 1100 series FTIR spectrophotometer, after grinding the sample with KBr. UV/Vis spectra of zeolite-encapsulated metal complexes were recorded in Nujol using a Shimadzu 1601 UV/Vis spectrophotometer by layering a mull sample to the inside of one of the cuvettes and keeping the other one layered with Nujol as reference. UV/Vis spectra of other ligands and neat complexes were recorded in methanol. X-ray powder diffractograms of solid catalysts were recorded using a Bruker AXS D8 advance X-ray powder diffractometer with a Cu-$K_\alpha$ target. Thermogravimetric analyses of pure as well as encapsulated complexes were carried out using a TG Stanton Redcroft STA 780 instrument. Scanning electron micrographs (SEM) of zeolite-containing samples were recorded with a Leo instrument, model 435VP. The samples were dusted on alumina and coated with a thin film of gold to prevent surface changing and to protect the surface material from thermal damage by the electron beam. In all analyses, a uniform thickness of about 0.1 mm was maintained. The energy-dispersive X-ray analysis (EDAX) plots of encapsulated complexes were recorded with an FEI Quanta 200 FEG instrument. The ESI-MS data were obtained with a Varian 500-MS LC ion-trap mass spectrometer operating either in the positive or in the negative mode. The EPR spectra were recorded with a Bruker ESP 300E X-band spectrometer. The spectra were measured at room temperature and at 77 K (with glasses, made by freezing solutions in liquid nitrogen, or just using the frozen samples). For the neat complexes we recorded spectra in DMF and in DMSO. In DMSO apparently there was precipitation of solids upon freezing, as only broad signals were obtained. The spin Hamiltonian parameters were obtained by simulation of the spectra with the computer program of Rockenbauer and Korecz.[34] All catalysed reaction products were analysed using a Thermoelectron gas chromatograph fitted with an HP-1 capillary column (30 m × 0.25 mm × 0.25 μm) and FID detector. Styrene, cyclohexene and methyl phenyl sulfide were used as external standards to quantify their conversion upon catalytic action. To quantify the conversion of styrene, for example, the calibration of the GC was carried out using styrene as external standard by injecting three different but known concentrations of styrene into the GC under the reaction conditions at which the analyses of catalytic products were performed and noting the peak area in each case. Finally, the peak area obtained for the remaining amount of styrene during catalytic oxidation was correlated with the peak area of the standard sample. This ultimately gave the percent conversion of substrate. The selectivity of products was then obtained directly from the peak areas of the respective products. Other external standards were used similarly. The identities of the products were confirmed by GC-MS with a Perkin–Elmer Clarus 500 model.

**X-ray Crystal Structure Determination:** Three-dimensional X-ray data were collected with a Bruker Kappa Apex CCD diffractometer by the $\phi$-$\omega$ scan method. Data were collected at room temperature. Reflections were measured from a hemisphere of data collected from frames each covering 0.3° in $\omega$. Of the 13687 reflections measured for **1** and 20715 for **2**, all of which were corrected for Lorentz and polarization effects, and for absorption by semiempirical methods based on symmetry-equivalent and repeated reflections, 2139 independent reflections for **1** and 8116 for **2** exceeded the significance level $|F|/\sigma(|F|) > 4.0$. Complex scattering factors were taken from the program package SHELXTL.[35] The structures were solved by direct methods and refined by full-matrix least-squares methods on $F^2$. The hydrogen atoms were included in calculated positions and refined by using a riding mode for **1** and were left to refine freely for **2**. Refinement converged with allowance for thermal anisotropy of all non-hydrogen atoms. Minimum and maximum final electron density: 2.494 and –2.167°e Å$^{-3}$ for **1**, 0.997 and –0.673°e Å$^{-3}$ for **2**. Crystal data and details on data collection and refinement are summarised in Table 8. CCDC-655305 (for **1**) and -655304 (for **2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

### Preparations

**Preparation of [Cu(pydx-en)] (1):** A stirred solution of $H_2$pydx-en (0.717 g, 2 mmol) dissolved in methanol (20 mL) was added to cupric acetate (0.40 g, 2 mmol) dissolved in methanol (30 mL) with stirring, and the reaction mixture was refluxed in a water bath for 5 h. On reducing the solvent volume to about 20 mL and keeping the mixture at ambient temperature, a brown solid of [Cu(pydx-en)] slowly separated within a few hours. This was filtered off, washed with methanol and dried in vacuo over silica gel. Yield: 78%. Green crystals suitable for X-ray diffraction study were ob-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

tained from the filtrate on slow concentration at room temperature. $C_{18}H_{20}CuN_4O_4$ [Cu(pydx-en)] (419.93): calcd. C 51.48, H 4.80, Cu 15.13, N 13.34; found C 52.0, H 4.6, Cu 15.1, N 13.1.

**Preparation of [Cu(pydx-1,3-pn)(MeOH)] (2):** [Cu(pydx-1,3-pn)(MeOH)] was prepared according to essentially the same procedure as for **1**. A green solid was obtained. Green crystals suitable for X-ray diffraction study were obtained from the filtrate on keeping it at room temperature for slow concentration. Yield: 70%. $C_{20}H_{26}CuN_4O_5$ [Cu(pydx-1,3-pn)(MeOH)] (466.0): calcd. C 51.55, H 5.62, Cu 13.64, N 12.02; found C 51.8, H 5.8, Cu 13.8, N 12.2.

**Preparation of Cu-Y:** Na-Y zeolite (5.0 g) was suspended in distilled water (300 mL) and after addition of cupric nitrate (2.26 g, 12 mmol), the reaction mixture was heated at 90 °C with stirring for 24 h. The pale bluish solid was filtered, washed with hot distilled water until the filtrate was free from any copper(II) ion content and dried at 150 °C in an air oven for 24 h. Found: Cu 7.60.

**Preparation of [Cu(pydx-en)]-Y (3):** Cu-Y (3.0 g) and $H_2$pydx-en (3.0 g) were mixed in methanol (50 mL), and the reaction mixture was heated under reflux in an oil bath with stirring for 14 h. The resulting material was filtered and then Soxhlet-extracted with methanol to remove unreacted ligand. It was finally treated with hot DMF while stirring for 1 h, filtered and washed with DMF followed by hot methanol. The uncomplexed metal ions present in the zeolite were removed by stirring with double-distilled aqueous NaCl (0.0.1 M, 150 mL) for 10 h. The resulting pale yellow solid was filtered, and washed with hot distilled water until no precipitate of AgCl was observed in the filtrate on treating with $AgNO_3$. Finally it was dried at 120 °C for several hours. Found: Cu 0.79.

**Preparation of [Cu(pydx-1,3-pn)]-Y (4):** The pale yellow [Cu(pydx-1,3-pn)]-Y was prepared according to essentially the same procedure as outlined for **3**. Found: Cu 0.74.

**Catalytic Activity**

**Oxidation of Styrene:** The catalytic oxidation of styrene was carried out in 50-mL flasks fitted with a water-circulated condenser. In a typical reaction, an aqueous solution of 30% $H_2O_2$ or 70% *tert*-butyl hydroperoxide (TBHP) (20 mmol) and styrene (1.04 g, 10 mmol) was mixed in acetonitrile (20 mL). After the temperature of the oil bath reached 80 °C, the zeolite-Y-encapsulated catalyst (0.025 g) was added to the reaction mixture which was continuously stirred. During the reaction, the products were periodically analysed using a gas chromatograph by withdrawing small aliquots, and their identities were confirmed by GC-MS. Various parameters, such as amounts of oxidant and catalyst as well as the temperature of the reaction mixture were studied in order to understand their effect on the conversion and patterns of the reaction products.

**Oxidation of Cyclohexene:** The catalytic oxidation of cyclohexene was also carried out using [Cu(pydx-en)]-Y and [Cu(pydx-1,3-pn)]-Y. Aqueous 30% $H_2O_2$ (2.28 g, 20 mmol), cyclohexene (0.82 g, 10 mmol) and catalyst (0.025 g) were mixed in acetonitrile (20 mL), and the reaction mixture was heated at 75 °C with continuous stirring in an oil bath. The progress of the reaction was monitored as mentioned above. The identification of the various products was confirmed by GC-MS.

**Oxidation of Methyl Phenyl Sulfide:** Aqueous 30% $H_2O_2$ (2.28 g, 20 mmol) and catalyst (0.025 g) were added to a solution of methyl phenyl sulfide (1.24 g, 10 mmol) dissolved in acetonitrile (20 mL), and the reaction mixture was stirred at ambient temperature for 3 h. The formation of the reaction products was monitored by GC.

**Measurement of UV/Vis Spectra by Adding $H_2O_2$:** A solution of complex **1** or **2** in methanol (ca. $10^{-4}$ M, 10 mL) was prepared and the UV spectra measured. A solution of $H_2O_2$ was prepared by dissolving five drops of 30% $H_2O_2$ in methanol (5 mL). One drop of this $H_2O_2$ solution was added and the UV spectra recorded again. Several similar additions were made, and after each addition the spectral changes were recorded similarly. As the solubility of complexes **1** or **2** is low in methanol, only the UV region could be covered in this way. For the visible region, the complexes were dissolved in DMSO (concentration about $10^{-3}$ M, 10 mL), and additions of the $H_2O_2$ solution were made similarly, now recording the visible region of the spectra (see insets of Figures 21 and 22).

# Red-to-Yellow Pressure-Induced Phase Transition in $Pt(bpy)Cl_2$: Spectroscopic Study Supported by DFT Calculations

**Rafael Valiente,*[a] Juan M. García-Lastra,[b] Pablo García-Fernández,[c] Sara García-Revilla,[d] and Oliver S. Wenger[e]**

**Keywords:** Phase transition / High-pressure chemistry / DFT calculations / Platinum(II) / Metal–metal interactions

The combination of spectroscopic and computational methods has been employed to explore the origin of the luminescence in the red and yellow forms of $Pt(bpy)Cl_2$. The luminescence of the red (linear-chain) form of $Pt(bpy)Cl_2$ (bpy = 2,2′-bipyridine) has been measured as a function of hydrostatic pressure up to 65 kbar. The luminescence band maximum is redshifted (–147 $cm^{-1}\,kbar^{-1}$), and the intrachain Pt–Pt distance decreases from 3.46 to 3.25 Å between ambient pressure and 17.7 kbar. Strong discontinuities in the optical properties at 17.7 kbar were interpreted in terms of a crystallographic phase transition from the red to a denser yellow form of $Pt(bpy)Cl_2$. First-principles calculations based on density functional theory were used to study the red to yellow phase transformation.

## Introduction

There is a continuing interest in the photophysical and chemical properties of $Pt^{II}$ complexes. The electronic structure of square-planar $Pt^{II}$ systems can be easily modified by ligand variation. Moreover, crystal packing has a strong effect on the nature of the lowest electronic states of these $d^8$ systems.[1] Optical spectroscopic studies are a particularly valuable technique for investigation of excited-state structures.[2] The anisotropic properties of the $Pt^{II}$ complexes in some solid-state structures indicate that stacking interactions can be used to tune the spectroscopic properties.[3–5]

Polymorphism in crystalline Pt(diimine) complexes is rather common. One example is $Pt(bpy)Cl_2$ (bpy = 2,2′-bipyridine), which has two types of stable crystal structures at room temperature:[5] a yellow form containing (more or less) isolated $Pt(bpy)Cl_2$ units and a red form in which there is Pt···Pt stacking. As a result, the electronic structures and, as a consequence, the optical spectroscopic properties are different in the two cases. Miskowski et al. as well as Gray et al. have found that the origin of the emissions from the yellow and red form are completely different even though the maximum of the emission bands are roughly the same at room temperature.[1,6] In the weakly luminescent yellow form, the $Pt^{II}$ complexes are spatially well separated from each other (the Pt–Pt distance is 4.44 Å), but in the strongly emitting red form the square-planar $Pt(bpy)Cl_2$ units stack to form an approximately linear Pt–Pt chain with a metal–metal spacing of 3.45 Å.[7] Previous investigations on $Pt^{II}$ linear-chain systems have shown that their electronic absorption and luminescence properties strongly depend on the intra-chain metal–metal separation.[4] Thus, modifications of the Pt–Pt distance induced by decreasing from room temperature (RT) to 20 K give rise to shifts of the luminescence band maximum of about 970 $cm^{-1}$ corresponding to an estimated reduction of the Pt–Pt distance by 0.08 Å.[7] However, the contribution of intrinsic and extrinsic temperature contributions to the emission band can be tricky to distinguish. The application of high pressure represents an extraordinary tool[2,8] that allows us to reduce the Pt–Pt distance in a continuous way. In this paper we will correlate the crystal and electronic structures by means of absorption and emission spectroscopy as well as density functional theory (DFT) calculations.

## Results and Discussion

In Figure 1 the RT luminescence spectra of $Pt(bpy)Cl_2$ at ambient pressure, 4.7, 12.1, 17.7, and 38.0 kbar (from bottom to top) after excitation at 22260 $cm^{-1}$ are shown. Within the square-planar symmetry the ambient-pressure luminescence band is assigned to the $\pi^*(bpy) \rightarrow d\sigma^*(Pt)$

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

luminescence transition (Figure 1).[7] The excitation spectrum at 16535 $cm^{-1}$ under the same conditions has also been obtained. The low-energy band responsible for the absorption edge was assigned to the $d\sigma^*(Pt) \rightarrow \pi^*$ (bpy) transition.[9] The required small crystal size precluded the measurement of a high-quality optical absorption spectrum even under ambient-pressure conditions.

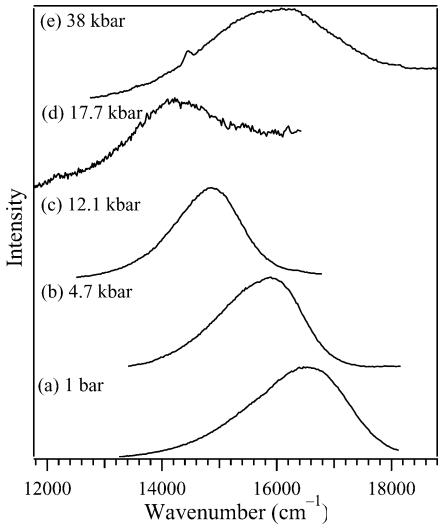

Figure 1. Room-temperature pressure dependence of the luminescence spectra of the red form of $Pt(bpy)Cl_2$.

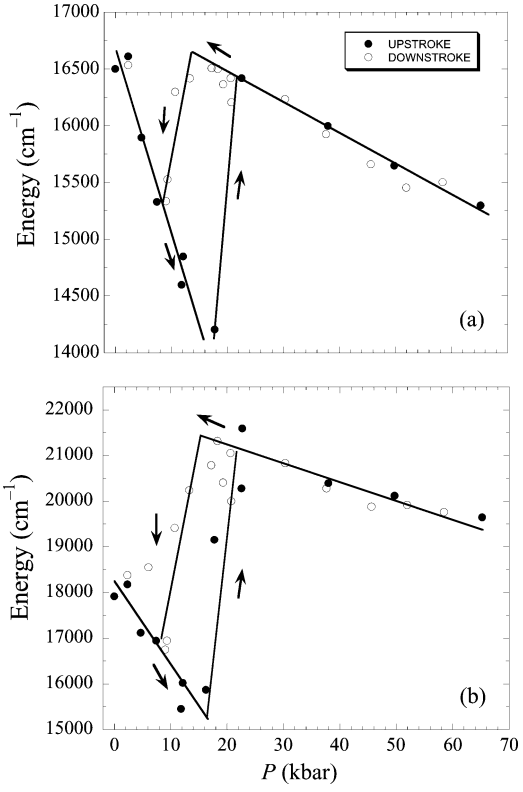

Figure 2. (a) Energy of the luminescence band maximum of the red form as a function of pressure; full circles correspond to increasing-pressure experiments and open circles to release-pressure experiments. (b) Energy of the excitation edge of the red form as a function of pressure; full circles correspond to increasing-pressure experiments and open circles to release-pressure experiments.

Figure 2 displays the pressure dependence of the emission-band maximum (a) as well as the absorption-edge energy in the excitation spectra (b) at RT. A shift to lower energies of the emission-band maximum and absorption edge is observed upon increasing the pressure from 1 bar to 17.7 kbar. At pressures higher than 17.7 kbar an abrupt blueshift is detected. Above this pressure a significant luminescence intensity decrease is observed. Moreover, the emission band broadens and the shape of the excitation spectrum alters. A change of the crystal color from orange to yellowish is observable when applying pressures larger than 17.7 kbar. Up to this pressure, the emission shift rate is –147 $cm^{-1}\,kbar^{-1}$. A similar pressure-dependent redshift of –99 $cm^{-1}\,kbar^{-1}$ was observed for crystalline $[Pt(SCN)_2\{\mu\text{-}(SCN)Mn(NCS)(bipy)_2\}_2]$.[10] Above 20 kbar the energy-band maximum is redshifted with a rate of –27 $cm^{-1}\,kbar^{-1}$ (Figure 2a). The solid lines are linear regression fits to the experimental data. Similar pressure behavior is observed for the absorption-edge energy in the excitation spectra (Figure 2b).

## Crystal and Electronic Structures of the Red and Yellow Forms at Ambient Pressure

The red form of $Pt(bpy)Cl_2$ crystallizes in the *Cmcm* orthorhombic space group where the units exhibit a parallel linear chain structure along the *c* axis.[7] The space between adjacent complexes within the chain is 3.45 Å. To avoid ligand interaction the neighboring complexes are alternatively rotated by 180° within the chain (Figure 3). Moreover, the $Pt^{II}$ atoms are somewhat displaced with respect to the *c* axis in a slight zigzag structure (ca. 161°). Angles and distances within the $Pt(bpy)Cl_2$ complex in the red form are similar to those in the yellow form, indicating that interaction between complexes in the red form does not perturb the molecular structure (Figure 4). In the yellow form, the distance between $Pt^{II}$ nearest neighbors is 4.44 Å.[11] In Table 1 we compare the experimental angles and distances in the yellow and red forms with those obtained after geometric optimization calculations. The large Pt–Pt distance in the yellow form clearly indicates the absence of any metal–metal interactions, allowing us to consider the molecular units as isolated monomers.

The symmetry of the $Pt(bpy)Cl_2$ complex is $C_{2v}$. A molecular orbital diagram of an isolated complex of this type is shown in Figure 5a. The interaction between complexes along the *z*-axis induces substantial changes in the electronic structure (see Figure 5). Within a dimer model, the $d_{z^2}$ orbital is strongly destabilized. The overlap of the $d_{z^2}$ orbitals of adjacent $Pt^{II}$ atoms leads to bonding $d\sigma$ and antibonding $d\sigma^*$ orbitals both of which are fully occupied (Figure 5b).[1]

Below a critical Pt–Pt distance, the highest occupied molecular orbital (HOMO) is $d\sigma^*$. Thus, the room-temperature luminescence of the red form of $Pt(bpy)Cl_2$ originates

| $N^1$–Pt–$N^2$ | 80.3 | 79.6 | 80.7 | – | 80 |

from a $^3$MLCT state and is associated with the π*(bpy) → dσ*(Pt) charge-transfer transition, i.e. the LUMO π* orbital is mainly centered on the bipyridine ligand. This is in contrast to the tetracyanidoplatinates, where the luminescence is due to a pσ*(Pt) → dσ*(Pt) transition.[12]

Under ambient-pressure conditions the luminescence of the red form of Pt(bpy)$Cl_2$ consists of an asymmetric band

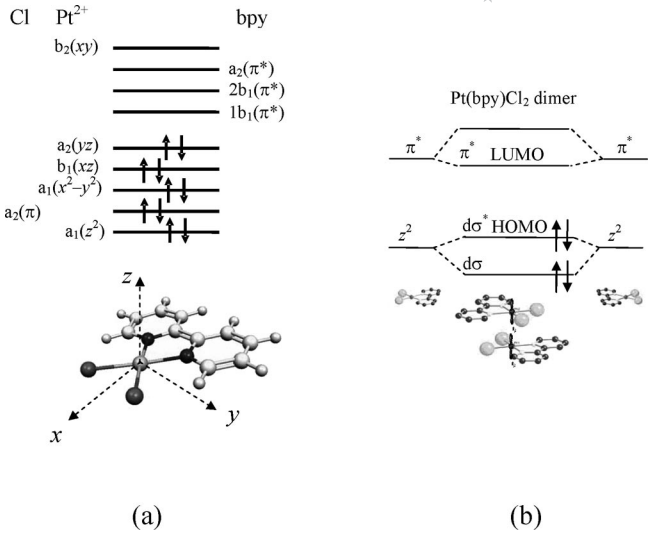

Figure 5. (a) Diagram of the frontier orbitals of the Pt(bpy)$Cl_2$ monomer and scheme showing the axis set chosen in the calculation. (b) Simplified energy-level scheme for the dimer model of Pt(bpy)$Cl_2$.

at 16535 $cm^{-1}$ associated with the π*(bpy) → dσ*(Pt) transition (Figure 1). The excitation spectrum of the 16535 $cm^{-1}$ luminescence is characterized by an excitation edge and a set of overlapping bands. It is similar to the polarized absorption spectrum of the red form of Pt(bpy)$Cl_2$ with $\mathbf{E}\perp\mathbf{c}$.[9] The temperature dependence of the emission spectrum of the red form showed a shift to lower energies. The observed behavior is due to the reduction of the Pt–Pt distance within the chain, which induces an increase in the splitting between dσ and dσ* orbitals and a reduction of the HOMO–LUMO energy gap. Gray et al. carried out temperature-dependent X-ray diffraction and luminescence experiments on the red form of Pt(bpy)$Cl_2$.[7] With decreasing temperature, the compound contracts anisotropically, the Pt–Pt separation decreases to 3.37 Å at 20 K, and this is accompanied by a –970 $cm^{-1}$ redshift of the emission-band maximum. This result reveals the following relation between the luminescence maximum $\nu_{max}$ and the Pt–Pt distance $R$ ($\nu_{max}$ and $R$ are in units of $cm^{-1}$ and Å, respectively) [Equation (1)].[7]

$$\nu_{max} = 29500 - 5.4\times10^5 R^{-3} \quad (1)$$

Considering that the implicit temperature term is negligible, it is possible to use this equation to calculate the pressure-dependent distance reduction.

## High-Pressure Measurements and DFT Calculations

Recently, we have explored the role of the intermolecular stacking interaction by tuning the spectroscopic properties of the linear Pt–Pt chains as a function of hydrostatic pressure.[13] In view of the lack of experimental high-pressure crystal structures, we assume the validity of Equation (1) for evaluating the Pt–Pt distance reduction upon pressure in the red form. Under this assumption we estimate that the

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Pt–Pt distance decreases from 3.46 Å at ambient pressure to 3.25 Å at 17.7 kbar. Our calculations suggest that pressure destabilizes the dσ* HOMO, but the bpy π* LUMO energy is only weakly pressure-dependent (Figure 6). Experimentally, as pressure is increased above 17.7 kbar, abrupt blue-shifts of 2500 $cm^{-1}$ and 2880 $cm^{-1}$ in the luminescence and excitation spectra (Figures 1 and 2) are observed. Our results indicated that this phase transition is likely due to the conversion of the red modification of $Pt(bpy)Cl_2$ to a high-pressure denser yellow form (HPYF), not necessarily the same yellow form observed at ambient pressure (APYF). There is no crystallographic data available for this new yellow form. Phase transitions induced by pressure have been reported previously for several $Pt(CN)_4^{2-}$ systems.[4] Some tetracyanidoplatinates exhibit similarly strong emission discontinuities due to first-order phase transitions that occur upon cooling to cryogenic temperatures.[4] Red $Pt(bpy)Cl_2$ does not undergo any phase transition even when cooled to 20 K.[7] Since the emission intensity of the APYF is much weaker than that of the red form, it has been proposed that APYF is a $^3$LF emitter.[6] The same argument could reasonably be applied for the HPYF, whose emission is also much weaker than that of the red form. Because of the similarity of the HPYF and APYF emissions and the densities of the red form and the APYF (2.56 and 2.65 $g\,cm^{-3}$, respectively), it could be thought that HPYF and APYF are the same phase. The emission maxima of $Pt^{II}$ $^3$LF states exhibit comparatively weak pressure dependences, with typical shift rates in the order of 10–40 $cm^{-1}\,kbar^{-1}$.[14] From our system, we find a shift rate of $d\nu_{max}/dP = -27\ cm^{-1}\,kbar^{-1}$ (Figure 2a), and a high-pressure emission bandwidth (FWHM) of 3065 $cm^{-1}$, close to the value of 4030 $cm^{-1}$ found for the emission bandwidth in yellow $Pt(bpy)Cl_2$ at 250 K at ambient pressure.[6] A somewhat narrower luminescence bandwidth at elevated pressures is to be expected, owing to diminished relative distortions of the emissive and ground states.[2,15] The same effect accounts for the narrower bandwidth associated with the 12 kbar luminescence of red $Pt(bpy)Cl_2$ (Figure 1c) relative to that observed in the ambient-pressure spectrum (Figure 1a). Finally, the order-of-magnitude decrease in luminescence intensity accompanying the phase transition at 17.7 kbar is also consistent with a change from red to yellow $Pt(bpy)Cl_2$, i.e. a change from charge transfer to ligand-field luminescence transitions. The room-temperature ambient pressure luminescence quantum yields of microcrystalline samples of these two compounds are known to differ by more than an order of magnitude.[5] Pressure-dependent excitation spectra confirm our interpretation of the crystallographic phase transition at 17.7 kbar: between 12 and 23 kbar the absorption edge shifts discontinuously from 15000 to 20325 $cm^{-1}$ (Figure 2b).

The character and reversibility of the phase transition was highlighted by the luminescence spectra as well as the excitation spectra recorded upon increasing and releasing pressure. Figure 2 shows that upon pressure release, the yellow-to-red phase transformation only occurs at 11.0 kbar. Therefore, there is a hysteresis in the luminescence properties of $Pt(bpy)Cl_2$ of about 8 kbar. The presence of this hysteresis indicates that HPYF and APYF are different phases. In the 11.0–17.7 kbar range, depending on the pressure history, the luminescence originates in the $^3$MLCT or in the $^3$LF state.

In our calculations, the long Pt–Pt distance and the similarities in geometry between the $Pt(bpy)Cl_2$ monomer units in the two modifications allow us to simulate the yellow form using a single in-vacuo monomer, while the red form is obtained by stacking two (dimer) or three (trimer) $Pt(bpy)Cl_2$ units. In this model, the effect of applying hydrostatic pressure is simulated by varying the Pt–Pt distance $R$.

The monomer geometry was first optimized at the B3LYP/lanl2dz level imposing $C_{2v}$ symmetry. The result of this calculation is summarized in Figure 4 (plain numbers), and a comparison with available experimental data[11] is shown in Table 1. The agreement between them is very good

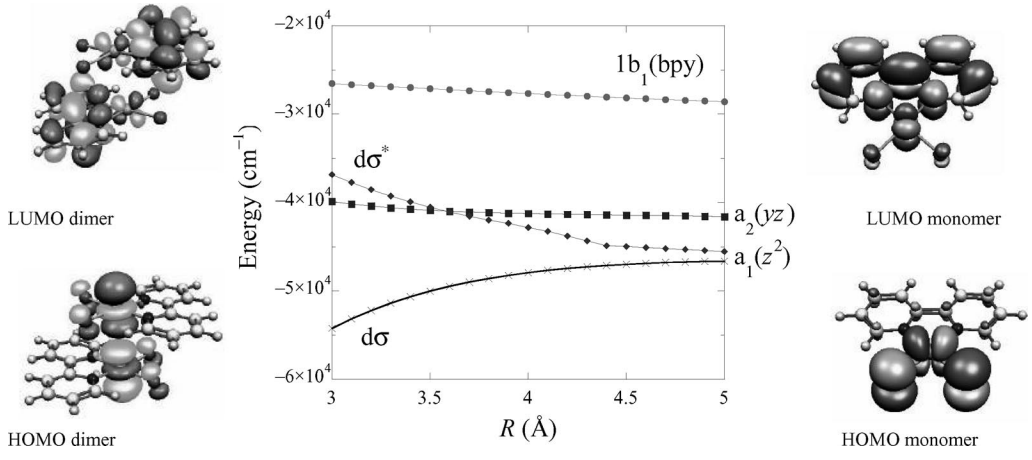

Figure 6. Variation of selected orbital energies of the $Pt(bpy)Cl_2$ dimer with the interlayer distance. Labels corresponding to the orbitals in the yellow and red form are shown on the right and left part of the plot, respectively. The antibonding dσ* orbital becomes the HOMO for $R$ values smaller than 3.6 Å after crossing with $a_2(yz)$, which corresponds to the HOMO in the monomer (yellow phase), reducing the HOMO–LUMO gap as $R$ is decreased.

with the exception of the Pt–Cl distance which is 0.08 Å longer in the calculations. A second optimization was carried out at the LDA/tzp level (italic numbers in Figure 4). In this case the Pt–Cl distance is in better agreement with experimental findings (see Table 1). In order to find the source of this error in the calculation we performed an LDA/lan2dz optimization that resulted in an overestimation of the Pt–Cl distance. Thus, we conclude that the longer distances found in these calculations are due to the basis set, possibly because the core–core interactions between the pseudopotentials found in the lanl2dz basis set are overestimated. This argument is supported by a BLYP/tzp level calculation (with exactly the same basis set as LDA/tzp). This resulted in a monomer geometry (Table 1) that is very close to the one calculated with LDA/tzp. As the agreement between the LDA/tzp geometries with those of the experiments is good (see Table 1), we use this geometry throughout this section to represent the monomer.

The symmetry, spacing, and character of the most important orbitals of Pt(bpy)$Cl_2$ as calculated in LDA are shown in Table 2 and Figure 5a, similar results were found when using B3LYP and BLYP.

Table 2. Energy and character of the most important orbitals of the Pt(bpy)$Cl_2$ monomer as obtained in LDA/tzp.

| Orbital | Energy [$cm^{-1}$] | Orbital character [%] Pt | Cl | bpy |
|---|---|---|---|---|
| | Unoccupied | | | |
| $b_2(xy)$ | 20810 | 46 | 34 | 20 |
| $a_2$ | 20485 | 2 | 0 | 98 |
| $2b_1$ | 18550 | 2 | 0 | 98 |
| $1b_1$ | 12420 | 4 | 0 | 96 |
| | Occupied | | | |
| $a_2(yz)$ | 0 | 27 | 70 | 3 |
| $b_1(xz)$ | –1050 | 31 | 64 | 5 |
| $a_1(x^2–y^2)$ | –2660 | 34 | 65 | 1 |
| $b_2$ | –3950 | 2 | 95 | 3 |
| $a_1(z^2)$ | –4030 | 84 | 12 | 4 |

According to Figure 5 and Table 2, the three occupied orbitals with highest energy, $a_2(yz)$, $b_1(xz)$, and $a_1(x^2–y^2)$, have a strong $Cl(p_\pi)$ character with very significant Pt(d) hybridization. The electrons in the lowest frontier orbital, $a_1(z^2)$, lie almost completely on the Pt ion and are perpendicular to the plane of the molecule. The LUMO and the next two orbitals above it are localized on the bpy ligand and have a strong π* character. The first unoccupied orbital mainly belonging to the $PtCl_2$ unit is $b_2(xy)$ which lies 20810 $cm^{-1}$ above the HOMO. These findings are similar to those reported for Pt(bpym)$Cl_2$.[16]

We have used the TD-B3LYP/lanl2dz method to calculate the low-lying excited states of the monomer. They are presented in Table 3 along with the estimation of the same transition energies by the ΔSCF method in LDA and BLYP. The reliability of these results is supported by the close agreement between the three different calculation methods. The energy of the most intense singlet-singlet transition, 21615 $cm^{-1}$, compares well with the position of the first peak in the absorption spectrum of the yellow form[17] lying at ca. 21000 $cm^{-1}$. This transition does not correspond to the HOMO–LUMO one, but it also has a strong dπ → π* character. The second most intense peak, $b_1(xz) \rightarrow 2b_1(\pi^*)$, $a_2(yz) \rightarrow a_2(\pi^*)$, is located at energies where the experimental spectrum presents another band. The emission spectrum of the yellow form is almost undetectable at RT.[5] For this reason and based on semiempirical extended Hückel calculations,[18] Miskowski et al.[19] proposed that the emission in the yellow form is due to a d-d $^3$LF transition.[6] In order to check this hypothesis we have performed a geometry optimization for the $^1B_1$ state [with the promoted electron in the $b_2(xy)$ orbital] and for the $^1B_2$ and $^1A_1$ states [with the promoted electron in the π*(bpy) orbital]. Results of these calculations are presented in Table 4. In the $^1B_1$ state the Pt–ligand distances increase very significantly with respect to those in the ground state: about 0.20 Å for Pt–N and 0.06 Å for Pt–Cl (Table 4). The ligand–Pt–ligand angles also change strongly. This fact leads to a large Stokes shift: the absorption $d\pi(Pt) \rightarrow b_2(xy)$ is at 22985 $cm^{-1}$, and the emission $b_2(xy) \rightarrow d\pi(Pt)$ is at 18145 $cm^{-1}$ (in the LDA calculations). In the case of $^1B_2$ and $^1A_1$ states, Pt–ligand distances and ligand–Pt–ligand angles hardly vary with respect to the ground state. However, an important reorganization takes place within bpy: the two pyridine rings approach each other; i.e. the $C^5$–$C^6$ distance is reduced by 5 pm. In the case of the $^1B_2$ excited state, this change in the bpy ligand produces an important Stokes shift, from 15890 $cm^{-1}$ in absorption to 14680 $cm^{-1}$ in emission. Since the calculated energy of the relaxed $^1B_2$ state is lower than the energy of $^1B_1$, in-vacuo single molecule DFT calculations predict that emission occurs from the first ($^1B_2$) state, in contrast to the experimental assignment by Miskowski et al. (in solution). In principle, the π*(bpy) → dπ(Pt) transition should have an emission intensity of the same order of magnitude as in the red form, because both seem to be predominantly $^3$MLCT. However, our theoretical calculations suggested that dπ(Pt) orbitals have a larger Cl(2p) character than Pt(d) ones (Table 1). In conclusion, the emission transition experimentally attributed to a π*(bpy) → dπ(Pt) transition[6] is likely to have mixed metal-to-ligand charge-transfer character with an important halide–ligand contribution.[16] This may well be the reason for its low intensity when compared to the red form where the HOMO is mostly a Pt($z^2$) orbital. Other experimental findings, like the lack of vibronic structure and large bandwidths, are also consistent with the variation of geometry of the $^1B_2$ excited state when compared to the ground state and provide further support for the assignment given here. A similar conclusion to the one reached here was presented in ref.[16] where this transition was assigned to a halide-to-ligand charge-transfer (XLCT). In that work the effect of solvents in the simulation was also checked, and it was found that the calculations reproduced well the experimental trends.

In the red form, the overlap between the $z^2$ orbitals on adjacent Pt atoms destabilized the dσ* dimer level. According to our calculations, the emission in the red form unambiguously comes from the π*(bpy) → σ*($z^2$, Pt) transition

| $^1B_2$ | $a_2(yz) \rightarrow 1b_1$(bpy) | 17340 | 0.0004 | 16370 | 17100 | ca. 19030 |
| $^1A_1$ | $b_1(xz) \rightarrow 1b_1$(bpy) | 21615 | 0.0057 | 17825 | 18790 | ca. 20970 |
| $^1A_1$ | $b_1(xz) \rightarrow 2b_1$(bpy)<br>$a_2(yz) \rightarrow a_2$(bpy) | 26695 | 0.0017 | 25245 | 26290 | ca. 25000 |
| $^1B_1$ | $a_2(yz) \rightarrow b_2(xy)$ | 28790 | 0.0000 | 22015 | 27100 | – |

(Figure 5b), which has a clear $^3$MLCT nature, and therefore is very intense (see below).

We have simulated the red form of $Pt(bpy)Cl_2$ by stacking two and three monomers on top of each other. As in the case of the monomer, the LUMO in these molecules has bpy(π*) character (Figure 6). However, the HOMO is strongly localized on the Pt atom and has $z^2$ character. Calculating the HOMO–LUMO transition for the dimer and trimer using the experimental separation between Pt ions leads to 18630 and 15240 $cm^{-1}$ energy gaps. A similar behavior is observed in experiments where the red-form emission energy is lowered when pressure is applied.

In order to understand the changes between the dimer (red phase) and the monomer (yellow phase) we have plotted in Figure 6 the energies of some selected orbitals of the dimer as a function of interlayer distance $R$. The energies of the monomer HOMO, $a_2(xy)$, and LUMO are quite insensitive to the application of pressure. Moreover, the LUMO is the same for the monomer and the dimer. However, the energy of the dimer orbitals, which at long distance become the monomer $a_1(z^2)$ ones, are strongly split in a bonding (dσ) and antibonding pair (dσ*) when $R$ is reduced. A reduction of the Pt–Pt distance increases the $z^2$ interaction destabilizing the dσ* dimer level. In fact, the dσ* orbital becomes the HOMO for $R$ values smaller than 3.6 Å, i.e. dσ* must be the HOMO in the red form. From that point onwards the Pt–Pt distance decrease is accompanied by a continuous reduction of the HOMO–LUMO gap that explains the shift of the emission to lower energies of the red form when compared with the yellow one. We have calculated the rate at which the HOMO–LUMO transition energy in the dimer changes when $R$ is varied around $R$ = 3.45 Å by the ΔSCF method and obtained $dE_{H-L}/dR$ = 7900 $cm^{-1}$ $Å^{-1}$. Taking into account the value of the experimental linear compressibility, $\chi_c = 3.4 \times 10^{-3}$ $kbar^{-1}$,[13] we estimate a redshift of –93 $cm^{-1}$ $kbar^{-1}$ for the emission upon pressure. This value compares reasonably well with the experimental value of –147 $cm^{-1}$ $kbar^{-1}$ considering the limitations of our models. Because the arrangement of the monomers in HPYF is unknown, it has not been possible to study the pressure dependence of the luminescence for this phase.

In Figure 7 the variation of the total energy of the dimer and trimer with the Pt–Pt separation in LDA calculation is represented. In the dimer, this curve presents a minimum at $R$ = 3.28 Å, which is reasonably close to the experimental $R_0$ value of 3.45 Å. When three instead of two $Pt(bpy)Cl_2$ units are used, the optimum interlayer separation is slightly shifted to 3.38 Å, significantly closer to the experimental value. From Figure 7 we learn that the inter-monomer potential is very anharmonic indicating that if the dimer is compressed enough, electrostatic repulsion becomes the dominant effect and a geometry with two independent, noninteracting $Pt(bpy)Cl_2$ molecules will be favored.

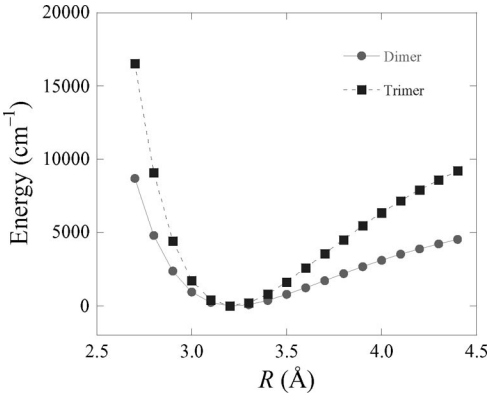

Figure 7. Total energy of the ground state of the $Pt(bpy)Cl_2$ dimer (circles) and trimer (squares) at the LDA/tzp level when the interlayer distance is varied.

Table 4. Description of the changes in the geometry of $^1A_1$, $^1B_2$, and $^1B_1$ with respect to the ground state for the same parameters as in Table 1. Positive values indicate an increase of the distances or angles with respect to the ground state. Distances are given in Å and angles in °. Energies obtained in LDA and BLYP calculations by the ΔSCF method for the emission and the corresponding Stokes shift are also shown. All energies are given in $cm^{-1}$.

## Conclusions

We present a theoretical interpretation of the red-to-yellow phase transition experimentally observed in $Pt(bpy)Cl_2$ microcrystals at high pressures. Our theoretical models are based on isolated $Pt(bpy)Cl_2$ units (to simulate the yellow form) and dimer and trimer units of this complex to simulate the stacked, linear-chain red form. DFT calculations allow us to analyze the differences between red and yellow phases observed experimentally in terms of the Pt–Pt distance. The appearance of hysteresis in the optical properties most probably indicates that the new yellow phase observed at high pressure and the ambient-pressure yellow phase are distinct phases. The calculations suggest that the high-pressure luminescence corresponding to the high-pressure yellow phase is a halide–ligand transition instead of a ligand-field transition. This is a clear example where a synergy between experimental and theoretical work is essential for understanding high-pressure effects.

## Experimental Section and Computational Details

**Synthetic Procedure:** $Pt(bpy)Cl_2$ samples of the yellow form were prepared as described in refs.[13,17,20]

**Spectroscopic Measurements:** Hydrostatic-pressure experiments were carried out in a diamond-anvil cell (High Pressure Diamond Optics, Inc.) using spectroscopic paraffin as the pressure-transmitting medium. Excitation and luminescence spectra were performed with a Jobin–Yvon FluoroMax-2 fluorometer with a microscope attached. An optic fiber guided the emission light to the fluorometer detection system. All the spectra were corrected for instrumental response. A pre-indented aluminum gasket with a 300-μm diameter hole (machined with a Natjet microdrill) was used. The applied pressure was measured through the redshift luminescence of the ruby R-lines. Ruby luminescence was excited with the 407 nm line of a $Kr^+$ laser (Coherent CR-500K) and dispersed by a Jobin–Yvon U1000 double-monochromator.

**DFT Studies:** The geometry of the electronic ground state of a single $Pt(bpy)Cl_2$ unit has been obtained using DFT calculations through the semiempirical hybrid functional B3LYP[21,22] and the LANL2DZ basis set which includes pseudopotentials to represent the core electrons. Time-dependent DFT (TDDFT) was later used to explore the position and character of several excited states at this level of theory. All these calculations were constrained to keep $C_{2v}$ symmetry. The Gaussian 98[23] program suite was employed. As a complement to the previous calculations the geometry of a $Pt(bpy)Cl_2$ molecule and the electronic structure of the monomer, dimer, and trimer for different values of the Pt–Pt distance and Pt–Pt–Pt angle were also calculated using the ADF package.[24] Two types of calculations were performed: (a) Using the local density approximation (LDA) within the VWN parameterization of the electron correlation[25] and (b) using the generalized gradient approximation (GGA) exchange-correlation through the Becke[21] functional for exchange and Lee–Yang–Parr[26] functional for correlation (BLYP). In both cases relativistic effects have been taken into account through the Zeroth-Order Regular Approximation (ZORA),[27] which includes the Darwin and mass-velocity terms, but not the spin-orbit interaction. All atoms were described through basis sets of TZP quality (triple-ζ STO plus-one polarization function) given in the program data base and taking into account all electrons (without any frozen-core or pseudopotential approximations). Electronic transition calculations at this level of theory were performed with the ΔSCF method. In the case of absorption spectra the ΔSCF method consists of a geometry optimization for the ground state, yielding the corresponding $E_1$ energy. At the same geometry the electronic configuration of an excited state is imposed, and the SCF procedure is performed again, to obtain the corresponding $E_2$ energy. The energy difference, $E_2 - E_1$, is taken as the electronic transition energy. For the emission spectra the procedure is similar, but in this case the geometry optimization is performed imposing the electronic configuration of the excited state, and the energy of the ground state is then calculated at that geometry.

**Keywords:** Platinum / Bridging ligands / N ligands / O ligands

Acidolysis of the complexes $[Pt(CH_3)(terpy)]Y$ (Y = $PF_6$, $CH_3SO_3$, $CF_3SO_3$, $ClO_4$, $BF_4$; terpy = 2,2′:6′,2′′-terpyridine) with an equimolar amount of $CH_3SO_3$ in 2,2,2-trifluoroethanol (TFE) affords the corresponding methanesulfonato derivatives $[Pt(OSO_2CH_3)(terpy)]Y$. When Y = $NO_3$ a nearly equimolar mixture of the methanesulfonato and nitrato complexes is obtained, whereas the reaction of $[Pt(CH_3)(terpy)](CF_3SO_3)$ with triflic acid in either dry TFE or $CH_2Cl_2$ gives the aqua species $[Pt(terpy)(H_2O)](SO_3CF_3)_2$ (**8′**), whose X-ray crystal structure is reported. This structure shows hydrogen bonding between the coordinated water molecule and two triflate ions. $^1H$ NMR evidence is reported that suggests that this hydrogen bonding is partially retained in $CD_3NO_2$ solution. The new hydroxido-bridged dimers $[Pt_2(\mu\text{-}OH)(terpy)_2](X)$ [X = $(ClO_4)_3$, $(PF_6)_2(CF_3SO_3)$ (**12**)] have been isolated and their X-ray crystal structures determined.

## Introduction

Complexes of the transition metals containing weakly bonded anions (e.g. $BF_4^-$, $CF_3SO_3^-$, etc.) are of great importance in coordination and organometallic chemistry as they can serve as useful precursors for the preparation of a wide range of complexes, many of which have been shown to be active catalysts.[1] Some of the various routes used for their preparation have been reviewed by Beck.[2] Among these synthetic methods, the acidolysis of a metal–alkyl bond is of particular utility since it gives no by-products. We have successfully applied this route for the preparation of $[Pt(OSO_2CF_3)(triphos)](CF_3SO_3)$ {triphos = bis[2-(diphenylphosphanyl)ethyl](phenyl)phosphane} by treating $[Pt(CH_3)(triphos)](CF_3SO_3)$[3] or $[Pt(CH_3)_2(triphos\text{-}P,P')]$[4] with $CF_3SO_3H$. Both these reactions give the triflato complex cleanly and in high yield.

We reasoned that acidolysis of a cationic complex of the type $[M(CH_3)(L)]Y$ (L = terdentate ligand) with an acid HY′ could also be useful for establishing the relative coordinating ability of the two anions Y and Y′. We chose 2,2′:6,2′′-terpyridine (terpy) as the terdentate ligand to take advantage of our own experience in the chemistry of $Pt^{II}$,[5–7] and $Au^{III}$(terpy)[8] complexes as well as of the impressive amount of existing literature data, particularly papers by Romeo et al. dealing with the $[Pt(CH_3)(terpy)]^+$ cation.[9–11]

It is well known that a terpy ligand gives rise to extensive charge delocalization in an expanded π system when coordinated to a metal ion.[12,13] This results in a remarkable increase in the electrophilicity of the metal center, and we expected that this would favor the interaction with hard ligands such those we were dealing with here.

Herein we report the results of the acidolysis of the complexes $[Pt(CH_3)(terpy)]Y$ (Y = $PF_6$, $CH_3SO_3$, $CF_3SO_3$, $ClO_4$, $BF_4$, $NO_3$) by $CH_3SO_3H$ and $CF_3SO_3H$ (Y = $CF_3SO_3$). The crystal and molecular structures of the aqua species $[Pt(terpy)(H_2O)](CF_3SO_3)_2$ and of $[Pt_2(\mu\text{-}OH)(terpy)_2](PF_6)_2(CF_3SO_3)$, which have been isolated in the course of this work, are also reported.

## Results and Discussion

Some of the starting complexes of the type $[Pt(CH_3)(terpy)]Y$ were prepared as described by Romeo et al.,[9] whereas the others (Y = $NO_3$, $BF_4$, $CH_3SO_3$ and $CF_3SO_3$) were obtained by treating $[Pt(CH_3)(terpy)](Cl)$ with a stoichiometric amount of the appropriate silver salt. All of them were dried under vacuum at 100 °C over $P_2O_5$ for at least 2 h before treatment with the acid.

### Reactions of the Methyl Complexes with $CH_3SO_3H$

The reactions between equimolar quantities of the methyl complexes $[Pt(CH_3)(terpy)]Y$ [Y = $PF_6$ (**2**), $ClO_4$ (**3**),

$CF_3SO_3$ (**4**), $BF_4$ (**5**), $NO_3$ (**6**), $CH_3SO_3$ (**7**)] and $CH_3SO_3H$ proceed readily in 2,2,2-trifluoroethanol (TFE) solution (room temp., 1 h) to yield the corresponding acidolysis products **2′**–**7′** in 80–90% yield (see Experimental Section). All complexes were characterized by microanalysis and $^1H$ NMR and IR spectroscopy.

The $CH_3SO_3$ resonance in the $^1H$ NMR spectra ($CD_3NO_2$) of complexes [Pt($OSO_2CH_3$)(terpy)]Y (**2′**–**5′**) appears as a singlet at $\delta$ = 3.11 ppm, which is 0.64 ppm downfield from that observed in the methanesulfonate salt **7**. Resonances for both the coordinated and ionic methanesulfonate are present in the spectrum of complex **7′** in a 1:1 ratio. Hence, exchange between these two species, if any, is slow on the NMR timescale. Complexes **2′**, **3′**, **4′**, **5′**, and **7′** display the same spectrum, which is characterized by three groups of lines, in the aromatic region (terpy ligand). The most downfield-shifted signal at $\delta$ = 8.86 ppm, attributable to $H^6$, is a doublet coupled with $H^5$ ($^3J_{H,H}$ = 5.6 Hz) with satellite peaks due to $^{195}Pt$ coupling ($^3J_{Pt,H}$ = 32 Hz). The signal at $\delta$ = 7.98 ppm is a doublet of doublets assignable to $H^5$ ($^3J_{H,H}$ = 5.6 and 7.5 Hz; $^4J_{H,H}$ = 2.0 Hz). The remaining multiplets at $\delta$ = 8.59–8.34 ppm belong to the other aromatic ring protons. On the whole, the pattern here is very similar to that of the corresponding methyl complexes.

IR spectroscopy confirmed the identity of the complexes also in the solid state. This was best proved by comparing the spectrum of the methanesulfonate complex salt **7** with that of **2′**, whose $PF_6^-$ counterion, which absorbs at 848 $cm^{-1}$, is transparent across the whole $\nu(SO_3)$ region (1000–1300 $cm^{-1}$). Thus, while **7** exhibits two strong absorptions at 1193 and 1038 $cm^{-1}$, which are typical values for the $\nu(SO_3)$ mode in ionic sulfonates, **2′** shows three peaks at 1275, 1150, and 1100 $cm^{-1}$. This increase in the multiplicity is typical of methanesulfonato complexes and is a consequence of a lowering of the symmetry of the $SO_3$ group upon coordination.[14] The analytical data for the acidolysis reaction product when Y = $NO_3$ (**6′**) are in keeping with the molecular formulation [Pt(terpy)($CH_3SO_3$)($NO_3$)]. The IR spectrum of the compound in the range 1300–1000 $cm^{-1}$ is somewhat complex due to the overlapping of similar vibration bands for the $NO_3$ and $SO_3$ groups. However, bands arising from both ionic and coordinated anions appear to be present. Thus, the strong absorptions at 1519 and 1350 $cm^{-1}$ can be assigned to coordinated and ionic $NO_3^-$, respectively, and those at 1275 and 1150 $cm^{-1}$ to covalent methanesulfonate, while the two bands at 1203 and 1045 $cm^{-1}$ are characteristic absorptions of ionic $CH_3SO_3^-$.

The $^1H$ NMR spectrum ($CD_3NO_2$) of **6′** displays two singlets in a 1:1 ratio at $\delta$ = 3.11 and 2.47 ppm due to coordinated and ionic $CH_3SO_3^-$, respectively. The aromatic region is characterized by peaks characteristic of the species [Pt($OSO_2CH_3$)(terpy)]$^+$ and other resonances which, in view of the above findings, can be attributed to the terpy ligand in the cation [Pt($ONO_2$)(terpy)]$^+$. In particular, the doublet at $\delta$ = 8.58 ppm, which is not present in the $^1H$ NMR spectra of the methanesulfonato complexes, is attributable to the $H^6$ terpy protons of [Pt($ONO_2$)(terpy)]$^+$. We conclude from these observations that the acidolysis product **6′** is actually a nearly equimolar mixture of the methanesulfonato and nitrato complex salts. This, in turn, indicates that the two anions are of nearly equal coordinating ability toward the Pt(terpy) center, as is found for their basicity towards the proton.[15]

The acidolysis reactions of complexes **2**, **3**, **4**, and **7** with a stoichiometric amount of acid were monitored by $^1H$ NMR spectroscopy for $CD_3NO_2$ solutions (0.02 mmol of complex in 1 mL of $CD_3NO_2$). With the exception of complex **7**, all reactions went to completion in the time required for mixing the reagents. Surprisingly enough, **7** reacts with the acid very much more slowly: even at 40 °C it takes more than one week to go to about 90% conversion. Only the starting and final products are observed in the NMR spectra at any one time. A possible explanation for the above finding may be the formation of a hydrogen-bonded couple between the acid and its conjugate base in $CD_3NO_2$ solution, perhaps similar to that found between $HNO_3$ and $NO_3^-$,[16] in other words [$CH_3O_2SO\cdots H\cdots OSO_2CH_3$]$^-$. Such an interaction is unlikely to exist in the protic solvent TFE, which is why there is no difference in reactivity between **7** and the other methyl complexes.

### Reactions of 4 with $CF_3SO_3H$

The reaction of [Pt(terpy)($CH_3$)]($CF_3SO_3$) with a stoichiometric amount of triflic acid in either TFE or $CH_2Cl_2$ gives a compound (**8′**) whose analytical data indicate the presence of water, which was not lost on heating the compound at 100 °C under vacuum over $P_2O_5$ for several hours. Repeated and careful attempts to rigorously exclude water during the preparations failed. Since the IR and NMR spectroscopic data were not conclusive, an X-ray diffraction structural study of the compound was deemed necessary. This showed the compound is actually the aqua species [Pt(terpy)($OH_2$)]($CF_3SO_3$)$_2$. This was a rather unexpected result, especially for the reaction conducted in $CH_2Cl_2$ since, as mentioned in the Introduction, we have previously found the same procedure to give the triflato complexes in the triphos and triphos-*P*,*P′* cases.

#### *Structure of [Pt(terpy)($H_2O$)]($CF_3SO_3$)$_2$ (8′)*

An ORTEP[17] view of [Pt(terpy)($H_2O$)]($CF_3SO_3$)$_2$ (**8′**) is shown in Figure 1. The coordination geometry around the platinum atom is distorted square-planar due to the constraints of the terpyridine ligand, which gives rise to a narrowing of N–Pt–N(*cis*) angles to 81.4(2)° and 81.8(2)°. These distortions are associated with a significant shortening of the Pt–N2 distance [1.914(4) Å] with respect to the Pt–N1 and Pt–N3 ones [2.021(5) and 2.009(4) Å, respectively], in agreement with the geometries observed in similar complexes of $Pt^{II}$ with ter- or tetradentate ligands.[18–23] The three coordinated terpy nitrogen atoms, the platinum atom, and the water oxygen atom lie approximately in the same plane with maximum deviations from this plane for O1 of 0.033(5) Å and for N2 of 0.025(5) Å. The water molecule is located in a plane nearly perpendicular [84(5)°] to the Pt1

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

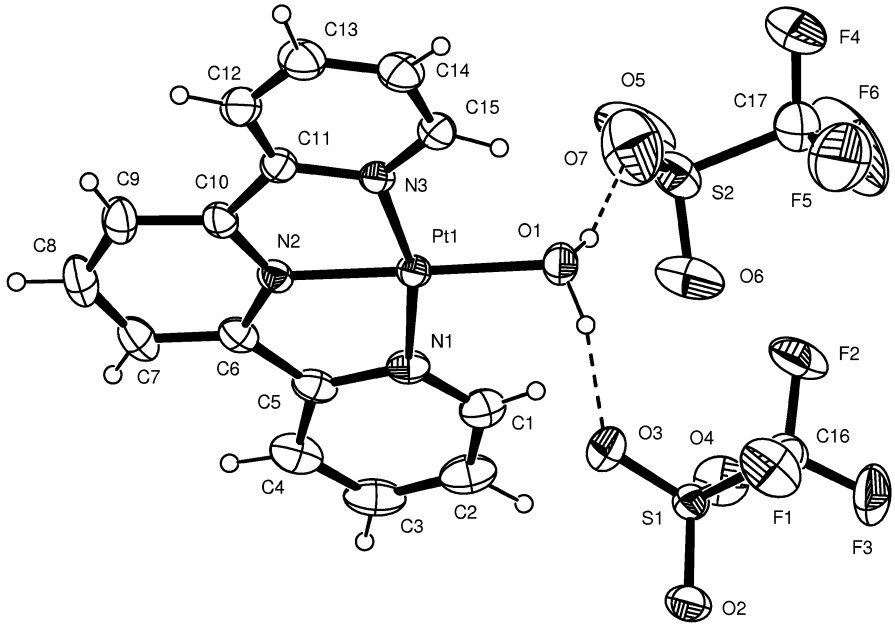

Figure 1. ORTEP view of $[Pt(terpy)(H_2O)](CF_3SO_3)_2$ displaying thermal ellipsoids at 30% probability. The dotted lines indicate hydrogen bonds.

basal plane and is linked to the oxygen atoms of two triflate anions by hydrogen bonds. The Pt–$OH_2$ distance [2.040(5) Å] compares well with the distances observed in $Pt^{II}$ square-planar complexes where a water molecule is *trans* to a nitrogen atom (range: 2.05–2.10 Å).[24] No stacking interactions between parallel molecular planes shorter than the sum of the van der Waals radii are observed.

### *IR and $^1$H NMR Spectroscopic Studies of the Aqua Complex $[Pt(terpy)(H_2O)](CF_3SO_3)_2$ (8′)*

The IR spectrum of complex **8′** shows three strong absorptions in the $\nu(SO_3)$ region at 1166, 1235, and 1290 $cm^{-1}$. In light of the structural results, this increase in multiplicity of the $\nu(SO_3)$ mode can now be straightforwardly ascribed to the lowering of the symmetry of the $SO_3$ group due to hydrogen bonding with the coordinated water molecule. It should be noted that an increase in multiplicity would also be expected if the triflate ion were coordinated to the metal center, although the splitting here is somewhat smaller than in the triphos and triphos-*P,P′* triflate complexes.[3,4]

We isolated the aqua complex as its perchlorate salt $[Pt(terpy)(H_2O)](ClO_4)_2$ (**10**) after treating the corresponding salt of the methyl complex with an excess of perchloric acid in TFE. The $^1$H NMR spectra of complexes **8′** and **10** in $CD_3NO_2$ solution are shown in Figure 2 (**8′**: spectrum A; **10**: spectrum C). In contrast to spectrum C, there are two doublets in the terpy-$H^6$ region of spectrum A, at $\delta$ = 8.76 and 8.67 ppm, both with a $^3J_{H,H}$ coupling constant of 5.6 Hz. Addition of lithium triflate to the solution of **10** causes an increase of the doublet at $\delta$ = 8.67 ppm and a corresponding decrease of the one at $\delta$ = 8.76 ppm (Figure 2, spectrum B).

The following further observations were made:
(i) The $^1$H spectrum of $[Pt(H_2O)(terpy)](SO_3CF_3)_2$ (**8′**) after saturation of the $CD_3NO_2$ solution with $LiClO_4$ becomes identical to that of the perchlorate derivative **10**.
(ii) The addition of increasing amounts of lithium triflate to the solution of **8′** causes an increase of the upfield doublet and a corresponding decrease in the downfield one. However, even on saturating the solution with the triflate salt, the downfield doublet can still be observed.

Among the possible explanations we considered for the above results, we can definitively rule out the formation of ion pairs (without hydrogen bonding) and/or dimerization/oligomerization through stacking interactions, which are known to affect the NMR spectra of some Pt(terpyridine) complexes.[9] We have never found evidence for stacking in nitromethane solutions for either monocationic methyl or methanesulfonato complexes. Moreover, this should be even more disfavored for a dicationic species such as the aqua complex. The $^1$H NMR spectrum of the similarly charged species $[Pt(CH_3CN)(terpy)]^{2+}$, which we have isolated as the triflate salt (see Experimental Section), does not show any tendency to undergo ion pairing in $CD_3NO_2$ solution.

A more likely explanation for the NMR spectra of derivatives **8′** and **10** and their behavior towards salt addition, which is supported by the X-ray data of **8′**, is the presence of a slow (on the NMR timescale) equilibrium between the $[Pt(terpy)(H_2O)]^{2+}$ species and a hydrogen-bonded adduct of the type $[Pt(terpy)(OH_2\cdots OSO_2CF_3)]^+$, this latter having the $H^6$ doublet at $\delta$ = 8.67 ppm in $CD_3NO_2$ solution. The addition of increasing amounts of lithium triflate to the solution, besides having the obvious effect of shifting the equilibrium towards the hydrogen-bonded adduct, also increases the ionic strength of the solution, which has the

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

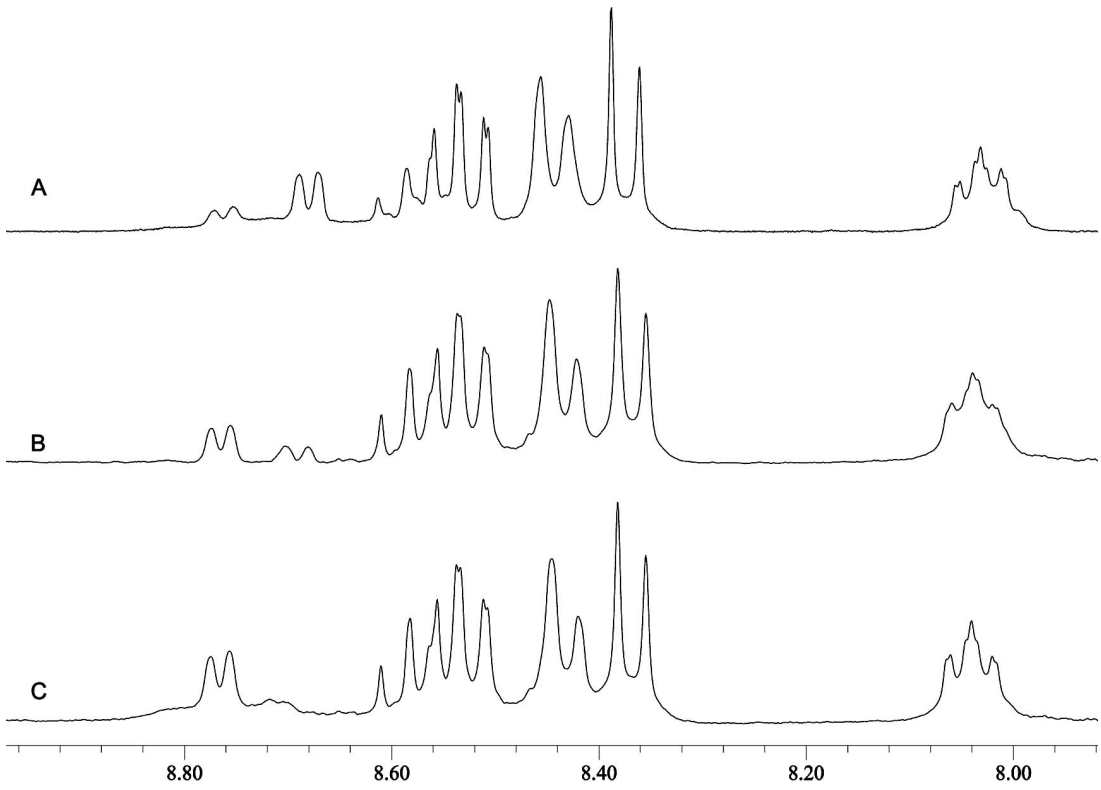

Figure 2. $^1$H NMR spectra ($\delta$ values in ppm) of [Pt(terpy)($H_2O$)]($SO_3CF_3$)$_2$ (A), [Pt(terpy)($H_2O$)]($ClO_4$)$_2$ + 1/2 equiv. $LiSO_3CF_3$ (B) and pure [Pt(terpy)($H_2O$)]($ClO_4$)$_2$ (C) in $CD_3NO_2$ at 298 K.

opposite effect. This explains why we still observe the downfield doublet even in solutions saturated with the triflate salt. The perchlorate ion, on the contrary, has a much lower (if any) hydrogen-bond-acceptor ability than triflate: It only increases the ionic strength and, when added in large amounts, completely shifts the equilibrium towards the $[Pt(terpy)(H_2O)]^{2+}$ species.

Some years ago, Lawrence et al. reported the isolation of a triflato complex after treating [PtCl(terpy)](Cl) with anhydrous $CF_3SO_3H$ which, on the basis of the analytical data, they formulated as [Pt($OSO_2CF_3$)(terpy)]($CF_3SO_3$)·$CF_3SO_3H$.[25] Unfortunately, the authors did not report IR or NMR spectroscopic data for their compound and, in our hands, attempts to follow their procedure always resulted in the isolation of intractable materials. As an alternative possible route to the synthesis of the triflato complex, we treated the methoxido complex [Pt(terpy)($OCH_3$)]($CF_3SO_3$) (**9**) with an excess of methyl triflate in $CH_2Cl_2$, as described in the Experimental Section. The following reaction was expected to occur: [Pt(terpy)($OCH_3$)]($CF_3SO_3$) + $CF_3SO_2OCH_3$ → [Pt($OSO_2CF_3$)(terpy)]($CF_3SO_3$) + $(CH_3)_2O$.

The IR spectrum of the isolated product (**12**) shows three strong absorptions in the $\nu(SO_3)$ region at 1167, 1248, and 1297 cm$^{-1}$, while that observed at 848 cm$^{-1}$ is typical of ionic $PF_6$. In the $^1$H NMR spectrum ($CD_3NO_2$), the resonance of the H$^6$ proton of the terpy ligand is a doublet at $\delta$ = 9.43 ($^3J_{H,H}$ = 5.0 Hz) ppm. Once again, an X-ray diffraction structural study was necessary to unequivocally establish the identity of the compound as [$Pt_2$(μ-OH)(terpy)$_2$]($PF_6$)$_2$($CF_3SO_3$).

### *Structure of [Pt$_2$(μ-OH)(terpy)$_2$](PF$_6$)$_2$(CF$_3$SO$_3$) (12)*

An ORTEP view of the $[Pt_2(\mu\text{-OH})(terpy)_2]^{3+}$·($CF_3SO_3$) fragment is shown in Figure 2. The coordination geometry around both platinum atoms is distorted square-planar, and the geometrical parameters around each Pt atom are similar to those observed in complex **8′**, with the N–Pt–N(*cis*) angles within the range 81.0(3)–82.1(3)° and central Pt1–N2 and Pt2–N5 bond lengths of 1.906(7) and 1.917(7) Å, respectively. The coordination planes including the Pt atoms make angles of 56.3(5)° and 53.2(4)° with the plane of the Pt1–O1–Pt2 bridge and are almost perpendicular to each other, being rotated by an angle of 79.1(2)°. The Pt–O distances between the platinum atoms and the negatively charged bridging hydroxido group [2.033(6) and 2.024(6) Å] are slightly shorter than the Pt–O(water) distances (2.04–2.10 Å) observed in the previous structure (**8′**) and in square-planar Pt$^{II}$ complexes where a water molecule is *trans* to a nitrogen atom.[24] The hydroxido group is hydrogen-bonded to the disordered triflate anion with an O1···O2 distance of 2.656(15) Å (Figure 3).

Interestingly enough, the same hydroxido-bridged dimer is obtained as its perchlorate salt [$Pt_2$(μ-OH)(terpy)$_2$]($ClO_4$)$_3$ (**11**) upon treating the methyl precursor with an excess of $HClO_4$ in water. We can draw this conclusion on the

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

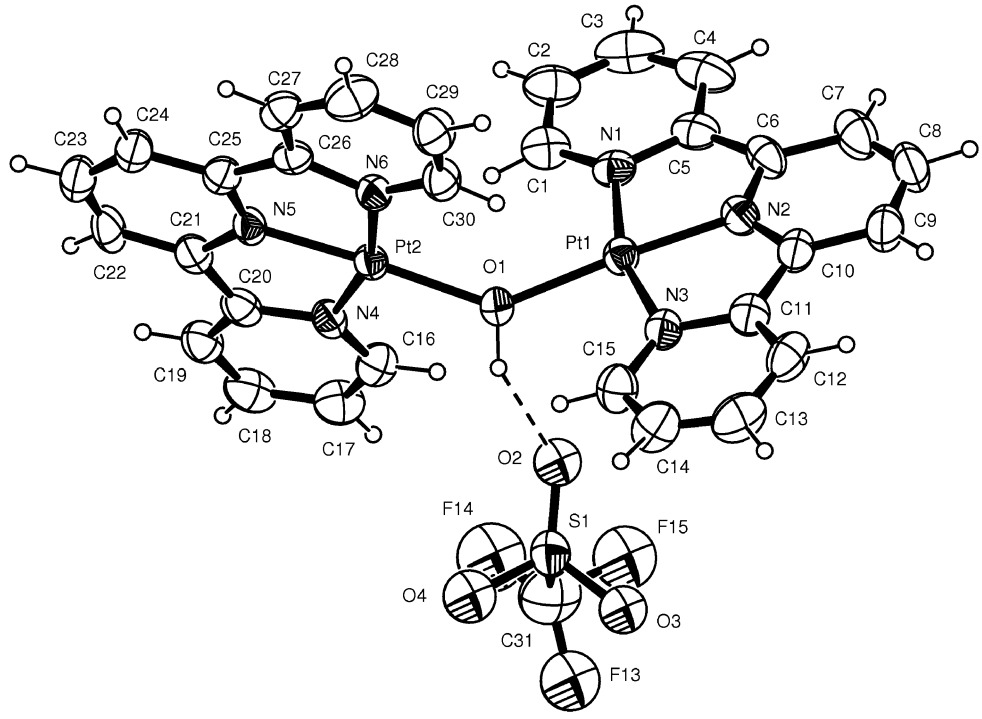

Figure 3. ORTEP view of the $[Pt_2(\mu\text{-}OH)(terpy)_2]^{3+}\cdot(CF_3SO_3)$ fragment displaying thermal ellipsoids at 30% probability. The dotted lines indicate hydrogen bonds.

basis of the analytical data and on the observation that the $^1H$ NMR spectra ($CD_3NO_2$) of the triflate hexafluorophosphate and perchlorate salts are identical. This latter result also indicates that, contrary to the case of the aqua species, the hydrogen bonding that is found in the solid state is not retained to any detectable extent in nitromethane solution.

## Conclusions

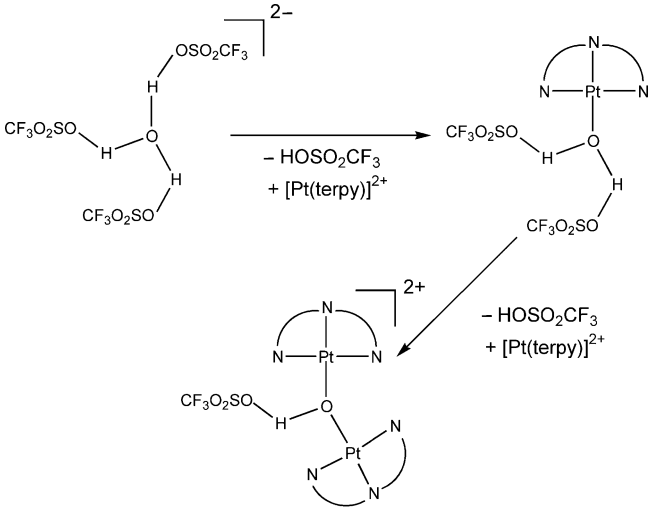
The $Pt^{II}$(terpy) system behaves differently from the triphos and triphos-*P*,*P*′ ones in that only the aqua species, instead of the triflato complex, is isolated after the acidolysis of $[Pt(terpy)(CH_3)]^+$ under similar experimental conditions. It has been shown that the terpy ligand remarkably enhances the reactivity toward nucleophilic substitution when coordinated to a metal ion[7,26] and, moreover, that the triflate ion is a very weak ligand. On these grounds, the possibility exists that the first formed product of the acidolysis reaction is the triflato species, which then rapidly solvolyses to the aqua species. Given that water was only adventitiously present in the solvents we used, the rate constant for the solvolysis has to be quite high indeed. Lawrence et al. have reported a value of 0.1 $s^{-1}$ for the rate constant of aquation of the triflato species they isolated in 0.1 M $CF_3SO_3H$.[25] On the other hand, since we have reported a value of $2.24\times10^{-2}$ $s^{-1}$ for the aquation of the $[Pt(terpy)Cl]^+$ species,[27] these two data would indicate a surprisingly low value of about 5 as the ratio of triflate/chloride lability. If so, aquation by adventitious water will be so slow that it is not likely to account for our experimental results. Considering the many examples of the unusual chemistry of (terpy)metal compounds reported in the literature, it might be possible that the mechanism of Pt–C bond fission is, in our case, different from that of the triphos and triphos-*P*,*P*′ ones. For example, it might be that it is not the bare proton that reacts to directly give the aqua species but the hydroxonium triflate instead. Some kinetic work is necessary, however, before any definitive conclusion can be drawn.

The isolation of $[Pt_2(\mu\text{-}OH)(terpy)_2](PF_6)_2(CF_3SO_3)$ (**12**) and its perchlorate analogue **11** is a rather noteworthy result and, although we did not pursue our investigation of the chemistry of these species further, a few considerations can nevertheless be made. First of all, species **11** can be isolated simply by changing the solvent from TFE, where the aqua species forms, to water. It might be reasoned that this is due to some reaction involving $[Pt(OH)(terpy)]^+$, which is formed by acid dissociation of the aqua species. This possibility can, however, be ruled out since any dissociation of the aqua species ($pK_a$ = 4.4)[26] is completely suppressed under our conditions (excess $HClO_4$). It is much more likely that, since extensive dimerization of the reactive $[Pt(CH_3)(terpy)]^+$ species occurs in water, whereas in solvents such as TFE it does not,[9] the dimers are the actual reactive species. All in all, this result further demonstrates, in a striking way, the preference of the Pt(terpy) center for water instead of the triflate ion.

Finally, it is interesting to note that the molecular structures of **8**′ and **12** can be considered as being derived from the structure of the triflic acid monohydrate[28] by replacing one or two $CF_3SO_3H$ molecules, respectively, with a

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

[Pt(terpy)]$^{2+}$ moiety, as depicted below (see Scheme 1). As such, this demonstrates once more the remarkable electrophilicity of the metal center caused by the terpyridine ligand.

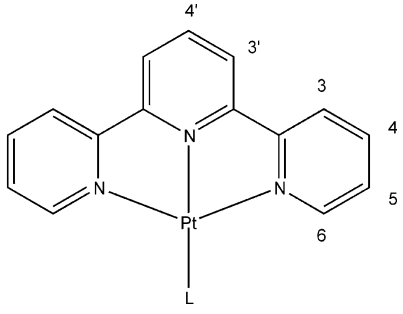


Scheme 1. Formal equivalence of the [Pt(terpy)]$^{2+}$ and $HOSO_2CF_3$ fragments in the monohydrate triflic acid, [Pt(terpy)($H_2O$)]-($OSO_2CF_3$)$_2$, and [Pt$_2$(μ-OH···$OSO_2CF_3$)(terpy)$_2$]$^{2+}$ crystal structures.

## Experimental Section

**Materials:** 2,2,2-Trifluoroethanol (TFE, 99% from Aldrich) was treated with a quantity of sodium calculated for a 2% water content and then distilled under dry nitrogen. The other solvents used were purified and dried by standard techniques. 2,2′:6′,2′′-Terpyridine and inorganic salts were purchased from Aldrich. Pt$^{II}$ precursors were prepared from platinum foils. Perchloric acid solution (65% in $H_2O$), methanesulfonic acid (>99.5%), triflic acid (>99%), and methyl methanesulfonate (>99%) were best-quality Aldrich products.

**Instrumentation:** IR spectra were recorded for nujol mulls between NaCl plates with a Nicolet Magna FT IR 750 or a Perkin–Elmer Spectrum One spectrometer. $^1$H NMR spectra were recorded with a Bruker Avance 300 or Bruker AC 200 F spectrometer. Chemical shifts (ppm) were referenced internally to the undeuterated solvent resonances and are quoted relative to tetramethylsilane ($\delta$ = 0 ppm). The protons of the terpy ligand are numbered as in Scheme 2. Elemental analyses were performed by the Microanalytical Laboratory of the University at Padua.



Scheme 2. Numbering of the hydrogen and primary carbon atoms of the coordinated terpy ligand.

**Preparation of the Complexes:** The complexes [Pt($CH_3$)(terpy)]Y [Y = Cl (**1**), $PF_6$ (**2**), $ClO_4$ (**3**), and $CF_3SO_3$ (**4**)] were prepared according to reported procedures.[9] Their chemical analyses are in good agreement with those obtained in previous preparations. The analogous $BF_4$ (**5**), $NO_3$ (**6**), and $CH_3SO_3$ (**7**) salts were prepared by treating the chlorido complex **1** (typically 0.1 g, 0.21 mmol) with a stoichiometric amount of the appropriate silver salt in water (approx. 15 mL). After stirring the mixture in the dark at room temperature for about 1 h, the AgCl was filtered off and the solvent completely removed under vacuum. The crude products were recrystallized from a TFE/diethyl ether mixture. In every case the yield was practically quantitative. **5:** $C_{16}H_{14}BF_4N_3Pt$ (530.19): calcd. C 36.2, H 2.66, N 7.93; found C 36.3, H 2.70, N 7.91. **6:** $C_{16}H_{14}N_4O_3Pt$ (505.39): calcd. C 38.0, H 2.79, N 11.1; found C 38.2, H 2.82, N 11.0. $^1$H NMR (**5**, **6**; $CD_3NO_2$): $\delta$ = 8.81 (d, $^3J_{H,H}$ = 5.9, $^3J_{Pt,H}$ = 51 Hz, 2 H, H$^6$), 8.53–8.25 (m, 7 H, H$^4$, H$^3$, H$^{3'}$, H$^{4'}$), 7.78 (ddd, $^3J_{H,H}$ = 5.9, $^3J_{H,H}$ = 7.5, $^4J_{H,H}$ = 1.8 Hz, 2 H, H$^5$), 1.03 (s, $^2J_{Pt,H}$ = 74 Hz, 3 H, Pt-C$H_3$) ppm. **7:** $C_{17}H_{17}N_3O_3PtS$ (538.48): calcd. C 37.9, H 3.18, N 7.80; found C 38.1, H 3.20, N 7.78. $^1$H NMR ($CD_3NO_2$): $\delta$ = 8.81 (d, $^3J_{H,H}$ = 5.9, $^3J_{Pt,H}$ = 51 Hz, 2 H, H$^6$), 8.53–8.25 (m, 7 H, H$^4$, H$^3$, H$^{3'}$, H$^{4'}$), 7.78 (ddd, $^3J_{H,H}$ = 5.9, $^3J_{H,H}$ = 7.5, $^4J_{H,H}$ = 1.8 Hz, 2 H, H$^5$), 1.03 (s, $^2J_{Pt,H}$ = 74 Hz, 3 H, Pt-C$H_3$), 2.47 (s, 3 H, C$H_3SO_3$) ppm. IR (nujol): $\tilde{\nu}$ = 1193, 1038 [$\nu(SO_3)$] cm$^{-1}$.

**[Pt(OH)(terpy)]($PF_6$) (8):** This complex was prepared according to a procedure reported for the analogous perchlorate salt[27] but with $KPF_6$ instead of $NaClO_4$ as the precipitating salt. Yield: 95%. $C_{15}H_{12}F_6N_3OPPt$ (590.32): calcd. C 30.5, H 2.05, N 7.12; found C 30.3, H 2.04, N 7.15. IR (nujol): $\tilde{\nu}$ = 3631 [$\nu$(OH)], 884 [$\nu(PF_6)$] cm$^{-1}$.

**[Pt(OCH$_3$)(terpy)]($PF_6$) (9):** The procedure of Aldridge et al.[29] was applied starting from [Pt(OH)(terpy)]($PF_6$) instead of the $BF_4^-$ salt. Yield: 90%. $C_{16}H_{15}F_6N_3OPPt$ (605.35): calcd. C 31.8, H 2.33, N 6.95; found C 31.6, H 2.32, N 6.98.

**[Pt(terpy)($H_2O$)]($ClO_4$)$_2$ (10):** ***Caution!*** *Perchlorate salts of metal complexes are potentially explosive and should be handled with care.* This complex was prepared by adding a slight excess of $HClO_4$ (23 μL of a 65% solution in $H_2O$) to a stirred solution of **3** (0.1 g, 0.18 mmol) in TFE (15 mL). After 1 h, the yellowish solution was concentrated under vacuum to about 3 mL, diethyl ether was added with stirring, and the pale-yellow precipitate that formed was collected by filtration, washed with diethyl ether, and dried under vacuum. Yield: 75% (0.087 g). $C_{15}H_{13}Cl_2N_3O_9Pt$ (645.26): calcd. C 26.6, H 1.93, N 6.20; found C 26.7, H 1.90, N 6.18. $^1$H NMR ($CD_3NO_2$): $\delta$ = 8.76 (d, $^3J_{H,H}$ = 5.6, $^3J_{Pt,H}$ = 29 Hz, 2 H, H$^6$), 8.61–8.35 (m, 7 H, H$^4$, H$^3$, H$^{3'}$, H$^{4'}$), 8.04 (ddd, $^3J_{H,H}$ = 5.6, $^3J_{H,H}$ = 7.5, $^4J_{H,H}$ = 1.6 Hz, 2 H, H$^5$) ppm.

**[Pt$_2$(μ-OH)(terpy)$_2$]($ClO_4$)$_3$ (11):** This species formed when the acidolysis of **3** with excess $HClO_4$ was conducted in water (30 mL) instead of TFE. In this case the reaction was much slower, and the mixture was refluxed for 2 h before most of the product had precipitated from the solution. This was concentrated to about 10 mL and the orange solid collected by filtration, washed with a little ice-cold water, and dried under vacuum over $P_2O_5$. Yield: 84% (0.089 g). $C_{30}H_{23}Cl_3N_6O_{13}Pt_2$ (1172.1): calcd. C 30.7, H 1.98, N 7.17; found C 30.5, H 2.00, N 7.20.

**[Pt$_2$(μ-OH)(terpy)$_2$]($PF_6$)$_2$($CF_3SO_3$) (12):** $CH_3OSO_2CF_3$ (0.1 mL, 0.9 mmol) was added to a suspension of **9** (0.3 g, 0.5 mmol), dried at 100 °C under vacuum over $P_2O_5$ just prior to use, in $CH_2Cl_2$

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

(15 mL) and the mixture stirred at room temperature for about 30 min. The orange solid was then collected by filtration, washed with diethyl ether, and immediately placed in a dessicator over $P_2O_5$. Yield: 95% (0.312 g). $C_{31}H_{23}F_{15}N_6O_4P_2Pt_2S$ (1312.7): calcd. C 28.4, H 1.77, N 6.40; found C 28.5, H 1.78, N 6.37. $^1$H NMR (**11**, **12**; $CD_3NO_2$, 298 K): $\delta$ = 9.43 (d, $^3J_{H,H}$ = 5.0 Hz, 2 H, H$^6$), 8.57 (t, $^3J_{H,H}$ = 8.0 Hz, 1 H, H$_4'$), 8.48–8.31 (m, 6 H, H$^3$, H$^{3'}$, H$^4$), 7.88 (ddd, $^3J_{H,H}$ = 7.0, $^3J_{H,H}$ = 6.0, $^4J_{H,H}$ = 2.0 Hz, 2 H, H$^5$) ppm. IR (nujol): $\tilde{\nu}$ = 1167, 1248, 1297 [$\nu$($CF_3SO_3$)], 848 [$\nu$($PF_6$)] cm$^{-1}$. Crystals of the compound, suitable for X-ray analysis were obtained by slow diffusion of diethyl ether into a saturated $CHCl_3$ solution.

**[Pt(terpy)($CH_3CN$)][($CF_3SO_3$)$_2$] (13):** The preparation of this complex has been reported by Field et al.,[30] but we preferred a different procedure. Thus, $CF_3SO_3H$ (10 μL, 0.11 mmol) was added to a stirred solution of **4** (0.06 g, 0.10 mmol) in acetonitrile (15 mL) under argon. After 1 h of stirring, the volume of the solution was reduced to about 3 mL by warming at 40 °C under a stream of argon. After cooling to room temperature, diethyl ether (20 mL) was added to precipitate a pale-yellow solid, which was filtered, washed with diethyl ether, and dried under vacuum. Yield: 91% (0.070 g). $C_{19}H_{14}F_6N_4O_6PtS_2$ (767.54): calcd. C 29.7, H 1.84, N 7.30; found C 29.5, H 1.79, N 7.22. $^1$H NMR ($CD_3NO_2$): $\delta$ = 8.86 (d, $^3J_{H,H}$ = 5.1, $^3J_{Pt,H}$ = 34 Hz, 2 H, H$^6$), 8.65–8.42 (m, 7 H, H$^4$, H$^3$, H$^{3'}$, H$^{4'}$), 7.98 (ddd, $^3J_{H,H}$ = 5.1, $^3J_{H,H}$ = 7.5, $^4J_{H,H}$ = 1.8 Hz, 2 H, H$^5$), 3.00 (s, $^4J_{Pt,H}$ = 9.0 Hz, 3 H, NCC$H_3$) ppm. IR (nujol): $\tilde{\nu}$ = 2330, 2307 [$\nu$(CN)]; 1260, 1158, 1030 [$\nu$($CF_3SO_3$)] cm$^{-1}$.

**Reactions of Complexes 2–7 with $CH_3SO_3H$:** These reactions were conducted in dry TFE. In a typical experiment, 1.0 mmol of the complex was dissolved in TFE (15 mL), and a solution of the acid (1.0 mmol) in the same solvent (2 mL) was added with stirring. In general, the solution became colorless within a few minutes. After stirring at room temperature for 1 h, the solution was concentrated to about 3 mL under vacuum, and diethyl ether was added dropwise with stirring. The resulting precipitate was collected by filtration, washed with diethyl ether, and dried under vacuum.

**[Pt($OSO_2CH_3$)(terpy)][$PF_6$] (2′):** Yield: 92% (0.615 g). $C_{16}H_{14}F_6N_3O_3PPtS$ (668.41): calcd. C 28.8, H 2.11, N 6.29; found C 28.9, H 2.07, N 6.39. IR (nujol): $\tilde{\nu}$ = 1275, 1150, 1100 [$\nu$ ($OSO_2$)], 848 [$\nu$ ($PF_6$)] cm$^{-1}$.

**[Pt($OSO_2CH_3$)(terpy)][$ClO_4$] (3′):** Yield: 90% (0.561 g). $C_{16}H_{14}ClN_3O_7PtS$ (622.89): calcd. C 30.9, H 2.27, N 6.75; found C 30.7, H 2.41, N 6.84.

**[Pt($OSO_2CH_3$)(terpy)][$CF_3SO_3$] (4′):** Yield: 87% (0.585 g). $C_{17}H_{14}F_3N_3O_6PtS_2$ (672.51): calcd. C 30.4, H 2.10, N 6.24; found C 30.2, H 2.22, N 6.28.

**[Pt($OSO_2CH_3$)(terpy)][$BF_4$] (5′):** Yield: 88% (0.537 g). $C_{16}H_{14}BF_4N_3O_3PtS$ (610.25): calcd. C 31.5, H 2.31, N 6.89; found C 31.6, H 2.44, N 6.82. $^1$H NMR (**2′**, **3′**, **4′**, **5′**; $CD_3NO_2$): $\delta$ = 8.86 (d, $^3J_{H,H}$ = 5.6, $^3J_{Pt,H}$ = 32 Hz, 2 H, H$^6$), 8.59–8.34 (m, 7 H, H$^4$, H$^3$, H$^{3'}$, H$^{4'}$), 7.98 (ddd, $^3J_{H,H}$ = 5.6, $^3J_{H,H}$ = 7.5, $^4J_{H,H}$ = 2.0 Hz, 2 H, H$^5$), 3.11 (s, 3 H, $SO_3CH_3$) ppm.

**[Pt($OSO_2CH_3$)(terpy)][Pt($ONO_2$)(terpy)][($CH_3SO_3$)($NO_3$) (6′):** Yield: 85% (0.498 g). $C_{16}H_{14}N_4O_6PtS$ (585.45): calcd. C 32.8, H 2.41, N 9.57; found C 32.6, H 2.47, N 9.62. $^1$H NMR ($CD_3NO_2$): $\delta$ = 8.87 (d, $^3J_{H,H}$ = 6.5, $^3J_{Pt,H}$ = 32 Hz, 2 H, H$^6$), 8.58 (d, $^3J_{H,H}$ = 6.0, $^3J_{Pt,H}$ = 27 Hz, 2 H, H$^6$), 8.59–8.31 (m, 14 H, H$^4$, H$^3$, H$^{3'}$, H$^{4'}$), 7.98 (m, 4 H, H$^5$), 3.11 (s, 3 H, $PtSO_3CH_3$), 2.47 (s, 3 H, $SO_3CH_3$) ppm. IR (nujol): $\tilde{\nu}$ = 1519 [$\nu$($ONO_2$)], 1360 [$\nu$($NO_3$)], 1275, 1150 [$\nu$($OSO_2$)], 1203, 1045 [$\nu$ ($SO_3$)] cm$^{-1}$.

**[Pt($OSO_2CH_3$)(terpy)][($CH_3SO_3$) (7′):** Yield: 87% (0.538 g). $C_{17}H_{17}N_3O_6PtS_2$ (618.54): calcd. C 33.0, H 2.77, N 6.79; found C 33.2, H 2.64, N 6.92. $^1$H NMR ($CD_3NO_2$): $\delta$ = 8.86 (d, $^3J_{H,H}$ = 5.6, $^3J_{Pt,H}$ = 32 Hz, 2 H, H$^6$), 8.59–8.34 (m, 7 H, H$^4$, H$^3$, H$^{3'}$, H$^{4'}$), 7.98 (ddd, $^3J_{H,H}$ = 5.6, $^3J_{H,H}$ = 7.5, $^4J_{H,H}$ = 2.0 Hz, 2 H, H$^5$), 3.11 (s, 3 H, $SO_3CH_3$), 2.47 (s, 3 H, $SO_3CH_3$) ppm.

**[Pt(terpy)($H_2O$)][($CF_3SO_3$)$_2$] (8′). Method (a):** $CF_3SO_3H$ (10 μL, 0.11 mmol) was added with a microsyringe fitted with a teflon needle to a stirred solution of **4** (0.06 g, 0.10 mmol) in freshly distilled TFE (10 mL) under dry argon. The color of the solution immediately turned from orange to pale yellow. After stirring for 30 min, diethyl ether (20 mL) was added, and the resulting yellow-orange precipitate was filtered off, washed with diethyl ether, and dried under vacuum. Yield: 91% (0.068 g). **Method (b):** All operations were performed under dry nitrogen with the aid of a glove box.

The acid (10 μL, 0.11 mmol) was added to a stirred suspension of **4** (0.06 g, 0.10 mmol) in dry $CH_2Cl_2$ (5 mL), and stirring was continued for about 15 min. The solid was then filtered, washed carefully with diethyl ether, and dried under vacuum. Yield: 91% (0.068 g). $C_{17}H_{13}F_6N_3O_7PtS_2$ (744.50): calcd. C 27.4, H 1.76, N 5.64; found (a) C 27.0, H 1.92, N 5.69; (b) C 27.1, H 1.83, N 5.72. $^1$H NMR ($CD_3NO_2$): $\delta$ = 8.76, 8.67 (2 d, 2 H, first d with $^3J_{H,H}$ = 5.6 Hz, second d with $^3J_{H,H}$ = 5.6 Hz, $H^6$), 8.61–8.35 (m, 7 H, $H^4$, $H^3$, $H^{3'}$, $H^{4'}$), 8.04 (ddd, $^3J_{H,H}$ = 5.6, $^3J_{H,H}$ = 7.5, $^4J_{H,H}$ = 1.6 Hz, 2 H, $H^5$) ppm. IR (nujol): $\tilde{\nu}$ = 1166, 1235, 1290 [$\nu(CF_3SO_3)$] cm$^{-1}$. Slow concentration of a chloroform solution of the product gave orange crystals suitable for X-ray crystal structure determination.

**X-ray Structure Determination:** Crystal data for compounds **8′** and **12** were collected using a Nonius Kappa CCD diffractometer with graphite-monochromated Mo-$K_\alpha$ radiation. The data sets were integrated with the Denzo-SMN package[31] and corrected for Lorentz, polarization, and absorption (SORTAV[32]) effects. The structures were solved by direct methods (SIR97[33]). The structure of **8′** was refined using full-matrix least squares with all non-hydrogen atoms anisotropic and hydrogen atoms isotropic. The non-hydrogen atoms of the dimeric $[Pt_2(\mu\text{-}OH)(terpy)_2]^{3+}$ complex cation and the $PF_6^-$ anion in the structure **12** were refined anisotropically. The other $PF_6^-$ anion as well as the triflate anion were found to be disordered. The fluorine and oxygen atoms of these groups were refined isotropically over two positions with an occupancy of 0.5 each; the P, C, and S atoms were refined anisotropically. All calculations were performed using SHELXL-97[34] and PARST,[35] as implemented in the WINGX[36] system of programs. The crystal data and refinement parameters are summarized in Table 1. Selected interatomic distances and angles are given in Tables 2 and 3 for compounds **8′** and **12**, respectively. CCDC-654357 and -654358 (for complexes **8′** and **12**, respectively) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# Octahedral Alkylbis(phenoxy-imine)tin(IV) Complexes: Effect of Substituents on the Geometry of the Complexes and Their Reactivity Toward Ionizing Species and Ethylene

**Liana Annunziata,[a] Daniela Pappalardo,*[b] Consiglia Tedesco,[a] and Claudio Pellecchia[a]**

**Keywords:** Tin / N,O ligands / Cations / Ethylene / Oligomerization

The synthesis and characterization of the organo-tin compounds $L_2SnR_2$ [L = *N*-(3,5-dichlorosalicylidene)aniline; R = $CH_3$ (**1**), R = $CH_2Ph$ (**2**)] and $L'_2SnR_2$ [**3**: L′ = *N*-(3-*tert*-butylsalicylidene)aniline, R = $CH_2Ph$] are described herein. NMR studies showed a highly symmetric structure for complex **1**, with the alkyl groups in a *trans* configuration, and the presence of at least two isomers in fluxional equilibrium for compounds **2** and **3**. Single-crystal X-ray characterization for compound **2** showed an octahedral geometry with the alkyl groups in *trans* relationship. The reactivity of the synthesized compounds toward ionizing agents was studied by NMR spectroscopy. For compounds **1** and **2** formation of cationic species through alkyl abstraction by $B(C_6F_5)_3$ was observed. For compound **3**, a cationic species was obtained by reaction with 1 equiv. of $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$; in this species a $\eta^n$ coordination of the benzyl group with the metal centre was recognized by NMR solution study. All the obtained cationic species promoted ethylene oligomerization under mild conditions, producing oligomers with saturated end groups and methyl branches. Oligoethylene end-group NMR analysis and deuteriolysis experiments excluded the migratory-insertion mechanism.

## Introduction

The activity in olefin polymerization of compounds based on metals beyond group 13 has never been reported in the literature.[1] Recently we reported the oligomerization of ethylene in the presence of bis(phenoxy-imine)dialkyltin(IV) complexes.[2] The latter compounds showed octahedral geometry with alkyl groups in a *cis* configuration and underwent alkyl abstraction reaction with the carbenium salt $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$. The obtained cationic species exhibited low activity in ethylene oligomerization under mild conditions, producing oligomers with saturated end groups and methyl branches. To the best of our knowledge, the oligomerization of ethylene by a group 14 compound is unprecedented in the literature.

These results prompted us to persist in exploring the reactivity of different salicylaldiminatotin(IV) complexes, in order to ascertain the mechanism involved in the formation of branched oligoethylenes. Therefore we studied the synthesis and the structural properties of novel dialkyl bis(salicylaldiminato)tin(IV) complexes, bearing electronically and sterically different ligands. These complexes revealed some interesting features that will be discussed here and compared with the previously reported results.

## Results and Discussion

### Synthesis of the Complexes

The synthesized bis(phenoxy-imine)tin(IV) complexes are described in Scheme 1. The *N*-(3-*tert*-butylsalicylidene)-aniline[3] and *N*-(3,5-dichlorosalicylidene)aniline[4] ligands were synthesized by a condensation reaction between the aldehyde and the aniline according to literature procedures. Complexes were prepared by a metathesis reaction of the sodium salt of the ligands with the corresponding dialkyltin(IV) chloride in tetrahydrofurane, producing compounds **1**–**3** with high yields (73–91%), as yellow or orange solids. The products are stable in an inert atmosphere, but easily underwent hydrolysis with formation of the free ligand in the presence of traces of adventitious water.

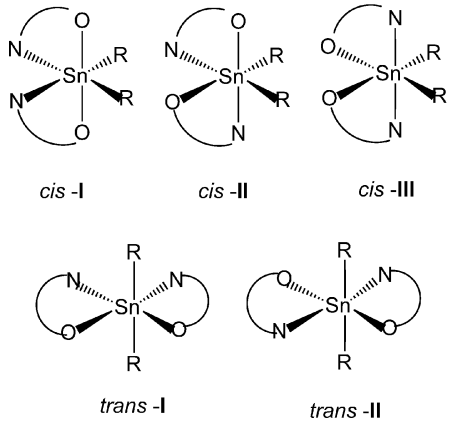
## NMR Characterization of the Complexes

All the synthesized compounds were characterized by $^{1}H$, $^{13}C$ and $^{119}Sn$ NMR spectroscopy, and mass spectroscopy. Compound **2** was also characterized by single-crystal X-ray diffraction analysis.

The $^{119}Sn$ NMR spectrum of the dimethyl compound **1**, bearing the chlorinated phenoxy-imine ligands, showed one signal at –306.5 ppm, compatible with the presence of a single organometallic species. The $^{1}H$ NMR spectrum showed very sharp signals and a pattern compatible with the presence of a highly symmetric structure in solution. Characteristic signals were the singlet at $\delta$ = 0.79 ppm ($^{2}J_{Sn,H}$ = 90.7 Hz) for the methyl groups, and the singlet at $\delta$ = 8.02 ppm ($^{3}J_{Sn,H}$ = 12.1 Hz) for the imine hydrogen atoms (C*H*=N). It is known from the literature that the coupling constants $^{2}J(^{119}Sn–^{1}H)$ and $^{1}J(^{119}Sn–^{13}C)$ can be used to estimate the methyl–tin–methyl angle.[5,6] For the previously reported bis(phenoxy-imine)tin(IV) dimethyl complexes, by using the equation specifically developed by Nelson for octahedral dialkyltin compounds,[6] we calculated a methyl–tin–methyl angle of 106(6)°, suggesting a structure with the methyl groups in a *cis* configuration; this result was nicely in agreement with the value disclosed by single-crystal X-ray analysis (107.4°). For compound **1** the value of the coupling constant $^{2}J_{Sn,H}$ for the methyl group bonded to tin is significantly higher than the value observed for previously reported compounds,[2] and the calculated angle C–Sn–C is of 160° (±6), in the expected range for a structure with the methyl groups in a *trans* configuration. For octahedral bis(phenoxy-imine) dialkyl complexes, five isomers are possible, as displayed in Scheme 2. In the present case, therefore, two isomers, "*trans*-**I**" and "*trans*-**II**", are compatible with the NMR spectroscopic data in solution.



Scheme 2.

The dibenzyl compound **2** showed two broad signals, at –425.6 and –426.9 ppm, in the $^{119}Sn$ NMR spectrum at room temperature, thus indicating the presence of different tin species in solution. In addition, in the $^{1}H$ NMR spectrum broad signals were also observed. Characteristic resonances are a singlet at $\delta$ = 2.56 ppm ($^{2}J_{Sn,H}$ = 105.1 Hz) for the methylene hydrogen atoms (C$H_2$Ph) and a singlet at $\delta$ = 7.84 ppm for the imine protons (C*H*=N). By using the Nelson equation,[6] from the value of the coupling constant $^{2}J_{Sn,H}$ for the methylene hydrogen atoms (C$H_2$Ph), the calculated angle for the C–Sn–C bonds was of 193° (±6), in the expected range for a structure with the benzyl groups in a *trans* configuration. As above, of the five possible isomers, the two "*trans*" ones are compatible with the NMR spectroscopic data in solution. Single-crystal X-ray diffraction analysis revealed that compound **2** crystallized in the "*trans*-**II**" isomeric form (vide infra).

In order to investigate the fluxional equilibrium between different isomers in solution, variable temperature $^{1}H$ NMR experiments were performed between 278 and 188 K. Lowering the temperature, the broad signals split (see electronic supporting information). At 203 K the signal of the methylene hydrogen atoms C$H_2$Ph split up into a well defined AB pattern at about 1.9 ppm, two broad signals at $\delta$ = 2.72 ppm ($^{2}J_{Sn,H}$ = 27.3 Hz) and 2.93 ppm, and a minor AB pattern ($\delta$ = 2.45 ppm). At lower field three main singlets ($\delta$ = 8.00, 7.74 and 7.66 ppm) and a minor one ($\delta$ = 7.56 ppm), attributable to the imine protons, were observed. Such observations are compatible with the presence of at least two main isomeric species and a minor one involved in fluxional equilibria.

The dibenzyl compound **3**, bearing the *N*-(3-*tert*-butylsalicylidene)aniline ligands, displayed an intricate $^{1}H$ NMR spectrum at room temperature (Figure 1). The compound must exist in solution in two isomeric forms, as evidenced by the presence, in the $^{119}Sn$ NMR spectrum, of two resonances at –456.5 ppm and –457.9 ppm (1:1 molar ratio). In the $^{1}H$ NMR spectrum, two sets of signals, attributable to two different species in a 1:1 ratio, were also recognized. The first signal set (one singlet at $\delta$ = 1.07 ppm for the *t*Bu group, one signal with AB pattern at 2.5 ppm for the diastereotopic methylene hydrogen atoms C$H_2$Ph and one singlet at $\delta$ = 7.99 ppm for the imine proton, with a $^{3}J_{Sn,H}$ of 33.65 Hz) is compatible with a highly symmetric species (**I**). The second signal set, compatible with a nonsymmetric species (**II**), consists of two singlets at $\delta$ = 1.28 ppm and 1.41 ppm for the *t*Bu groups, two signals with AB pattern for the C$H_2$Ph at 2.4 ppm and 2.7 ppm and two singlets for the imine hydrogen atoms at $\delta$ = 7.69 ppm and 7.89 ppm. The $^{13}C$ NMR spectrum of compound **2** coherently displayed two signals sets, one compatible with a symmetric species **I**, the second one compatible with a nonsymmetric species **II**. Variable-temperature $^{1}H$ NMR experiments, performed between 273 and 353 K, indicated the presence of a fluxional equilibrium between species **I** and **II**. On increasing the temperature the signals of species **II** collapsed into one signal set, attributed to the symmetric species **I** (Figure 2). At 333 K only one AB signal set for the C$H_2$Ph hydrogen atoms, centred at $\delta$ = 2.70 ppm, and only one singlet at $\delta$ = 7.83 ppm ($^{3}J_{Sn,H}$ = 16.20 Hz) for the imine hydrogen atoms (C*H*=N) were observed. Unfortunately, we were not able to measure the coupling constants $^{2}J$(Sn–H) for the methylene H atoms C$H_2$Ph, and consequently to estimate the geometry of the benzyl ligands around the tin. We were unable to observe the coalescence temperature for the two species up to 373 K. The $^{119}Sn$ NMR spectrum, performed

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

at this temperature in $C_6D_5Cl$, still showed two resonances at –456.2 and –457.6 (in 1:0.45 ratio). We previously observed a fluxional equilibrium between two different isomeric species for the analogous bis[*N*-(3-*tert*-butylsalicylidene)anilinato]dimethyltin(IV) compound through NMR spectroscopy.[2] In that case two species (a $C_2$-symmetric one and a $C_1$-symmetric one) were frozen out at 195 K, while the coalescence temperature $T_c$ was observed at 278 K in the $^1$H NMR spectra and at 333 K in the $^{119}$Sn NMR spectra. It is worth noting that the presence of bulkier benzyl ligands in compound **3** instead of methyl groups slows down the fluxional equilibrium, freezing out the isomers already at room temperature.[7]

## X-ray Diffraction Analysis

Compound **2** was crystallized from methylene chloride/hexane at room temperature. Crystal data are given in the Experimental Section and selected bond lengths and angles are listed in Table 1. A distorted octahedral geometry with the alkyl group in a *trans* configuration and the two oxygen atoms in *trans* position was disclosed (Figure 3). The tin atom is located on a crystallographic inversion centre and the benzyl moieties coordinated in a $\eta^1$ mode. The six-atom ring Sn1–N1–C1–C2–C7–O1 is quite planar (rmsd 0.073) with an envelope angle (between the five-atom plane N1–C1–C2–C7–O1 and the Sn1–N1–C1 plane) of 9.39(14)°.

Table 1. Selected bond lengths [Å], bond angles and torsion angles [°] for compound **2**. Symmetry equivalent atoms are indicated with an asterisk.

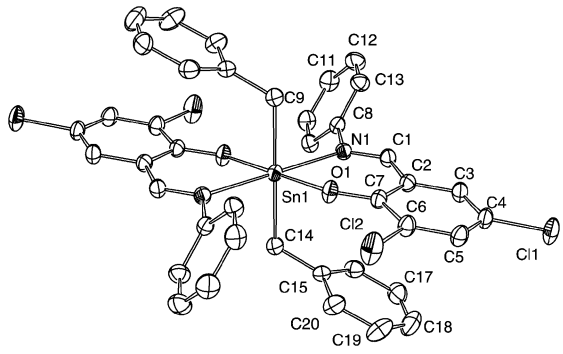

Figure 3. Molecular structure of compound **2**. Thermal ellipsoids are drawn at 30% probably level. Hydrogen atoms have been omitted for clarity.

It is worth noting that the analogous bis[*N*-(3-*tert*-butylsalicylidene)aniline]tin(IV) dialkyl complexes and the bis[*N*-(3-*tert*-butylsalicylidene)-2,3,4,5,6-pentafluoroaniline]tin(IV) dimethyl compound were crystallized in the *cis*-**I** isomeric structure, displaying the two oxygen atoms *trans* to each other and the alkyl ligands and the nitrogen atoms in a *cis* relationship.[2] Steric factors could explain the difference in the coordination environment at the central tin atom. The presence of chlorine atoms *ortho* to oxygen atoms of the phenoxy-imine ligand probably plays a role, and could favour ligand disposition in the plane.

Notably there are very few structurally characterized octahedral bis(phenoxy-imine)$MR_2$ compounds (M = any metal, R = alkyl or halogen atom) presenting the R ligands in a *trans* relationship.[8]

## Generation of Cationic Species

The synthesis of free cationic species of group 14 elements is a tricky task, because of their high reactivity. In the literature, examples of organotin cations are quite rare. Among them are the remarkable crystal structures of Lambert et al.'s trismesityl stannylium cation displaying a trigonal planar geometry around tin,[9] Sekiguchi et al.'s "stable and free" tin cation bearing three tris(alkyl)silyl ligands[10] and Michl et al.'s tributylstannylium carboranate.[11] On the contrary, organotin cationic compounds stabilized by the

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

ligand's intramolecular interactions or by external donor atoms are well known and have also been structurally characterized.[12]

In previous work, in order to mimic the active species in homogeneous olefin polymerization catalysis, we pursued cationic species with the formula $L_2SnR^+$ (L = phenoxy-imine; R = alkyl). For this purpose we used ionizing reagents, such as $[(C_6H_5)NH(CH_3)_2]^+[B(C_6F_5)_4]^-$, $B(C_6F_5)_3$ and $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$, traditionally used in homogeneous Ziegler–Natta catalysis. The alkyl abstraction reaction from the dimethyl- and dibutyl-bis(phenoxyimine)tin(IV) compounds was successfully obtained by the carbenium salt $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$. Reactions with $[(C_6H_5)NH(CH_3)_2]^+[B(C_6F_5)_4]^-$ and $B(C_6F_5)_3$ led instead to degradation products. The obtained cationic species exhibited some activity in the oligomerization of ethylene under mild conditions, producing short-chain oligomers, with saturated end groups and methyl branches.[2] Now these studies have been extended to the new synthesized complexes, and are reported herein.

Reactions of complexes **1**–**3** with $[(C_6H_5)NH(CH_3)_2]^+[B(C_6F_5)_4]^-$ led to decomposition, producing free phenoxy-imine ligands.

Compounds **1** and **2**, bearing the chlorinated phenoxy-imine ligand, displayed similar reactivity toward ionizing agents. Actually, reaction with $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$ resulted invariably in mixtures of decomposition products, while the reaction with $B(C_6F_5)_3$ produced the abstraction of an alkyl group. For instance, the reaction of compound **1** with 1 equiv. of $B(C_6F_5)_3$ rapidly produced a cationic species (**1a**) by methyl abstraction, as indicated by the presence in the $^1$H NMR spectrum of a resonance at $\delta$ = 0.42 ppm attributable to the methyl group of the "free" anion $[CH_3B(C_6H_5)_3]$.[13] The $^{119}$Sn NMR spectrum of species **1a** showed only one signal at –394.0 ppm. The pattern of signals in the $^1$H NMR spectrum was compatible with the presence in solution of one symmetric species, having a ligand/methyl signals integral ratio consistent with a 2:1 formulation. According to the formation of a stannylium cation, all the resonances were downfield shifted, if compared with the corresponding resonances for the neutral compound **1** in the same condition. Characteristic resonances are the singlet at 1.042 ppm for $SnCH_3$ ($^2J_{SnH}$ = 101.8 Hz) and the singlet at $\delta$ = 8.54 ppm for the imine proton ($^3J_{SnH}$ = 22.3 Hz).[14]

Reaction of compound **2** with 1 equiv. of $B(C_6F_5)_3$ produced a new mono-benzyltin species (**2a**), characterized by a signal at –500.0 ppm in the $^{119}$Sn NMR spectrum. In the $^1$H NMR spectrum characteristic resonances are a singlet at $\delta$ = 3.28 ppm for $SnCH_2Ph$ ($^2J_{SnH}$ = 117.0 Hz) and a singlet at $\delta$ = 8.47 ppm due to imine proton ($^3J_{SnH}$ = 18.2 Hz). However, in the $^1$H NMR spectrum of species **2a** the signals for the expected byproduct $[PhCH_2B(C_6F_5)_3]^-$ were absent. In addition, the $^{19}$F NMR spectrum showed a large number of resonances of comparable intensity, clear indication of the existence of more than one fluorinated species in solution, probably generated by aryl/alkyl group exchange reactions.[15]

Compound **3** displayed a different behaviour from compounds **1** and **2**. Reaction of compound **3** with $B(C_6F_5)_3$ led to degradation, while reaction with 1 equiv. of $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$ produced abstraction of one benzyl group and formation of the cationic species **3a**. Consistently, in the $^1$H NMR spectrum (Figure 4), the species $PhCH_2C(C_6H_5)_3$ was identified as a byproduct.[16] In the $^{119}$Sn NMR only one resonance at –448.7 ppm was observed. In the $^1$H NMR spectrum, characteristic resonances are one singlet at $\delta$ = 1.34 ppm for the *tert*-butyl hydrogens, one singlet at $\delta$ = 3.27 ppm ($^2J_{SnH}$ = 118.84 Hz) for the methylene H atoms and one singlet at $\delta$ = 8.53 ppm ($^3J_{SnH}$ = 14.92 Hz) for the imine hydrogen C*H*=N. The signal pattern is compatible with the presence of one symmetric species in solution, and shifted at higher frequency, if compared with the corresponding resonance for the neutral compound **3** in the same solvent.

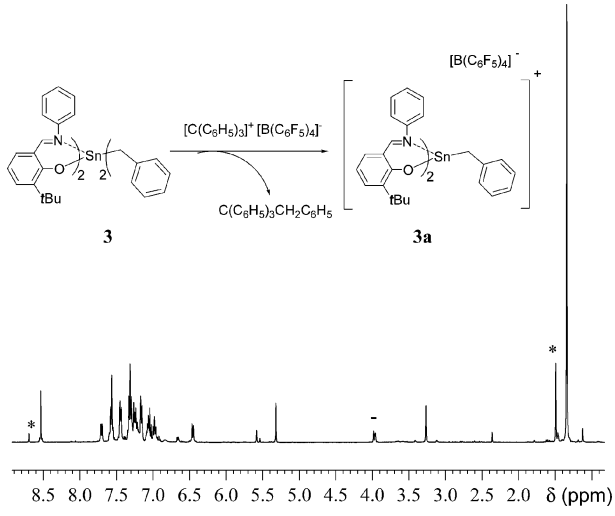

Figure 4. $^1$H NMR spectrum ($CD_2Cl_2$, 298 K) of compound **3a**: (*) "free" ligand impurities; (■) $C(C_6H_5)_3CH_2C_6H_5$.

The benzyl ligand can interact with electron-deficient metal centres also through the π-aromatic system. The $\eta^n$ ($n > 1$) coordination is typical of transition metals;[17] among main group elements, $\eta^3$ interaction has been observed, in the solid state, for benzyl lithium.[18] Latesky et al. found NMR spectroscopic evidence to detect this type of interaction in solution.[19] In particular, $\eta^n$ benzyl ligands are characterized by a high-field shift for the *ortho* hydrogen resonance ($\delta < 6.8$ ppm) in the $^1$H NMR, and by large $^1J_{CH}$ values for the $CH_2$ group ($J > 130$ Hz). The increase of the coupling constant can be explained with an increased "sp$^2$" character of the α-carbon, involving a decrease of the Mt–C–Ph angle. Interestingly, in the NMR spectra of cationic species **3a** we observed an upfield shift of the *ortho* benzyl hydrogens' resonance ($\delta$ = 6.44 ppm), and a $^1J_{CH}$ value for the methylene carbon of 139.8 Hz. The value observed is higher than that observed in tetrabenzyltin ($^1J_{CH}$ = 133 Hz), usually taken as a model for a normal σ bond ($\eta^1$) benzyl ligand.[20] These spectroscopic features thus suggest that in the cationic species **3a** the benzyl ligand interacts with the tin also through the π-aromatic system. Therefore

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

a $\eta^n$ ($n > 1$) coordination for the benzyl ligand can be hypothesized.

In order to study the influence of the temperature on the coordination of the benzyl to the tin atoms, $^1$H NMR spectra were recorded at lower temperature (between 278 K and 193 K). The aliphatic regions of the $^1$H NMR spectra for the cationic species **3a** are shown in Figure 5. On decreasing the temperature, the singlet of the methylene hydrogen atoms Sn$CH_2$Ph split up into an AB pattern, indicating that they are diastereotopic. At 233 K the doublet attributable to the *ortho* benzyl hydrogen atoms at $\delta$ = 6.44 ppm showed satellite peaks due to the tin–hydrogen spin–spin coupling with $J_{SnH}$ of 33.7 Hz. Similar NMR control experiments performed for the tetrabenzyltin compound at 233 K displayed a singlet for the methylene hydrogen atoms Sn$CH_2$Ph at $\delta$ = 2.16 ppm ($^1J_{CH}$ = 132.6 Hz) and a doublet for the *ortho* benzyl hydrogen atoms at $\delta$ = 6.60 ppm with a $J_{SnH}$ of 14.9 Hz.

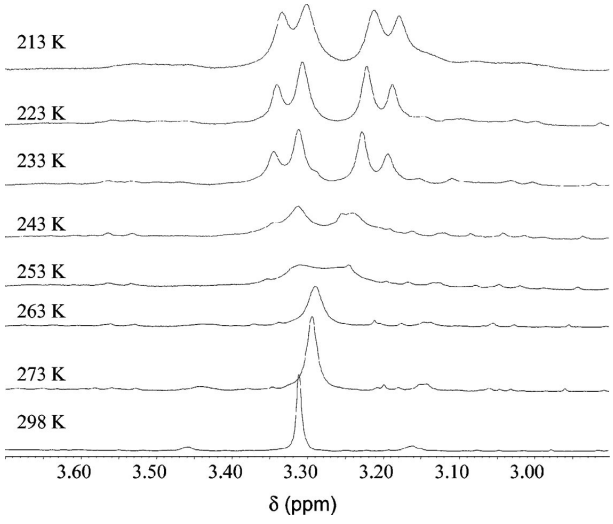

Figure 5. $^1$H NMR spectra of aliphatic region of compound **3a** at variable temperature ($CD_2Cl_2$).

In conclusion, these observations (i.e., the AB pattern for the methylene hydrogen atoms and the unusually high value of $J_{SnH}$ for the *ortho* benzyl hydrogen atoms) support the hypothesis that $\eta^n$ coordination of the benzyl to tin is fluxional (probably through a suprafacial metal shifting) and slows down at low temperature.

It is worth nothing that the cationic species **1a** and **2a** displayed an upfield shift for the $^{119}$Sn NMR signals in comparison with the resonances of the corresponding neutral compounds **1** and **2**. A similar behaviour was previously observed for the analogous bis[*N*-(3-*tert*-butylsalicylidene)anilinato]dimethyltin(IV) compound.[2] On the contrary, the $^{119}$Sn NMR resonance for **3a** displayed a downfield shift (about 10 ppm) in comparison with the resonance of the corresponding neutral compound **3**. This peculiar feature could be attributed to the different coordination sphere, because of the presence in **3a** of the intramolecular coordination of the benzyl aromatic ring.

A π interaction of the benzyl group to the tin centre was previously recognized by NMR for the cationic species $Tip_2SnBz^+$ (Tip = 2,4,6-triisopropylphenyl).[21]

## Reactivity Toward Ethylene

We disclosed that the ethylene oligomerization reaction is promoted by dimethyl- and dibutyl-bis(phenoxy-imine)-tin(IV) complexes, activated by the carbenium salt.[2] The obtained oligoethylene oily product had short chains, with saturated end groups and methyl branches. This result constituted the first example of oligomerization of ethylene by a group 14 compound, and prompted us to investigate the reactivity of different bis(phenoxy-imine)tin(IV) complexes toward ethylene.

Compound **3** in combination with $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$ and compounds **1** or **2** in combination with $B(C_6F_5)_3$ were able to oligomerize ethylene under mild conditions, affording short-chain oligomers (40–60 carbon atoms, estimated by NMR), with saturated end groups and methyl branches. The activities were always very low, and comparable with those observed with previously reported compounds.[2] These results suggest that the structural and electronic properties of the salicylidene-aniline ligands, while influencing the structure of the complexes and their reactivity toward ionizing agents, do not control the ethylene oligomerization activity, at least in the presence of the used catalysts, and under the explored experimental conditions.

Chain end-group analysis was used as a tool to understand the initiation and termination steps of the oligomerization mechanism. Actually, the initiation step is not the olefin insertion into the Sn–alkyl bond. In fact, the obtained oligomers always had saturated *n*-propyl end groups, even when the oligomerization tests were performed in the presence of compounds **2** and **3**, for which a benzyl end group would have been expected on the basis of the ethylene insertion in the Sn–$CH_2$Ph bond. Moreover, the absence of unsaturated end groups in all the sample indicated that the β-hydrogen elimination mechanism is not involved in the termination step.

In order to gain deeper insight into the termination step, some oligomerization runs were quenched with $CH_3OD$. Incorporation of deuterium was not observed; therefore the main termination step is not the hydrolysis of the metal–(growing chain) bond.

End-group NMR analysis and deuteriolysis experiments therefore seem to exclude the migratory-insertion mechanism typical of Ziegler–Natta polymerization catalysis.

In order to establish if a different mechanism could be involved in the formation of branched oligoethylenes, further oligomerization tests were performed in the presence of radical additive and proton-trapping agents. The yields and nature of the products were unaffected by the presence of the radical initiators (dicumyl peroxide, dibenzoyl peroxide) or of the radical inhibitor 2,2,6,6-tetramethylpiperidine *N*-oxide. Analogously, the presence of the proton-trapping

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

2,6-di-*tert*-butylpyridine did not have an effect on the oligomerization results.

While the insertion mechanism can be definitely excluded, at the moment a conclusive answer on the origin of the branched oligoethylenes cannot be given.

## Conclusions

Three new octahedral bis(phenoxy-imine)tin(IV)dialkyl complexes have been synthesized and fully characterized by $^{1}H$, $^{13}C$ and $^{119}Sn$ NMR and mass spectroscopy. Single-crystal X-ray analysis was obtained for compound **2**, showing an octahedral geometry with alkyl groups in *trans* relationship. Compounds **1** and **2** reacted with $B(C_6F_5)_3$ by alkyl abstraction producing cationic species, identified by NMR spectroscopy. For complex **3**, bearing the *N*-(3-*tert*-butylsalicylidene)aniline ligands, cationic species were instead obtained by reaction with $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$. Interestingly, in this latter species $\eta^n$ coordination of the benzyl group with the metal centre was recognized by NMR study. The obtained cationic species promoted ethylene oligomerization under mild conditions. Mechanistic studies, based on chain end-group NMR analysis and deuteriolysis experiments, excluded a migratory-insertion mechanism typical of Ziegler–Natta olefin polymerization catalysis.

## Experimental Section

**General Procedure:** Manipulation of sensitive materials was carried out under nitrogen using Schlenk or glove-box techniques. Hexane, tetrahydrofuran (THF) and toluene were refluxed over sodium/benzophenone, dichloromethane over calcium hydride, then distilled under nitrogen prior to use. $CDCl_3$, $CD_2Cl_2$ and $ClC_6D_5$ were dried with $CaH_2$ and distilled prior to use. $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$ was purchased from Boulder SPA Company and $B(C_6F_5)_3$ from Strem Chemicals. $Cl_2Sn(CH_2C_6H_5)_2$ was synthesized according to the literature.[20] The phenoxy-imine ligands *N*-(3-*tert*-butylsalicylidene)aniline[3] and *N*-(3,5dichlorosalicylidene)aniline[4] were synthesized according to literature procedures. NMR spectra were recorded with a Bruker Advanced 400 MHz spectrometer ($^{1}H$, 400 MHz; $^{13}C$, 100 MHz; $^{119}Sn$, 149 MHz; $^{19}F$, 376 MHz). The $^{119}Sn$ NMR were measured relative to $Sn(CH_3)_4$. EI-MS data were obtained with a Finnigan Thermoquest GCQ Plus 200 spectrometer using a direct insertion probe. Elemental analyses were recorded with a Thermo Finnigan Flash EA 1112 series C,H,N,S Analyzer.

**Synthesis of Bis[*N*-(3,5-dichlorosalicylidene)anilinato]dimethyltin-(IV) (1):** A solution of *N*-(3,5-dichlorosalicylidene)aniline (1.4 g, 5.26 mmol, in 60 mL of THF) was added dropwise to a stirred solution of NaH (252 mg, 10 mmol) in THF (10 mL) at 0 °C. The mixture was warmed to room temperature and stirred for 3 h. The resulting light yellow solution was added to a stirred solution of $Cl_2Sn(CH_3)_2$ (577 mg, 2.63 mmol) in 20 mL of THF at 0 °C. The mixture was warmed to room temperature and stirred overnight. Removal of the solvent in vacuo gave a brown powder. The crude product was extracted with toluene; the solution was concentrated to 15 mL and stored at –20 °C. An orange solid deposited overnight (1.6 g, 91%). $^{1}H$ NMR (400 MHz, $CDCl_3$, 25 °C): $\delta$ = 8.01 (s, $^{3}J_{SnH}$ = 12.1 Hz, 2 H, N=C*H*) 6.90–7.34 (m, 14 H, Ar*H*), 0.79 (s, $^{2}J_{SnH}$ = 90.7 Hz, 6 H, Sn$CH_3$) ppm. $^{13}C$ NMR (100 MHz, $CDCl_3$, 25 °C): $\delta$ = 164.8 (N=*C*H), 159.2, 150.2, 134.2, 132.2, 129.9, 129.1, 127.0, 122.8, 121.6, 120.8 (Ar-*C*), 8.7 (Sn-$CH_3$) ppm. $^{119}Sn$ NMR (149 MHz, $CDCl_3$, 25 °C): $\delta$ = –306.5 (s) ppm. EI-MS: *m*/*z* (%) 664 (10) [$M^+ - CH_3$], 649 (27), 614 (33), 413 (100). $C_{28}H_{22}Cl_4N_2O_2Sn$ (679.014): calcd. C 49.52, H 3.26, N 4.12; found C 49.98, H 3.31, N 3.99.

**Synthesis of Bis[*N*-(3,5-dichlorosalicylidene)anilinato]dibenzyltin-(IV) (2):** This compound was prepared as illustrated above, but using $Cl_2Sn(CH_2C_6H_5)_2$ (768 mg, 2.06 mmol in 20 mL of dry THF), 1.1 g of *N*-(3,5-dichlorosalicylidene)aniline (4.13 mmol in 50 mL of dry THF) and 150 mg of NaH (2.06 mmol) (yield 1.55 g, 43%). Yellow crystals, suitable for single-crystal X-ray diffraction analysis were grown from dichloromethane/hexane at room temperature. $^{1}H$ NMR (400 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 7.84 (br. s, 2 H, N=C*H*), 6.78–7.35 (m, 24 H, Ar*H*), 2.56 (br. s, $^{2}J_{SnH}$ = 105.1 Hz, 4 H, $CH_2$Ph) ppm. $^{13}C$ NMR (100 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 169.07 (N=*C*H), 119.6–150.4 (Ar-*C*), 37.5 (Sn-$CH_2$Ph) ppm. $^{119}Sn$ NMR (149 MHz, $CDCl_3$, 25 °C): $\delta$ = –425.6 (s), –426.9 (s) ppm. EI-MS: *m*/*z* (%) 740 (35) [$M^+ - CH_2Ph$], 565 (43), 530 (100). $C_{40}H_{30}Cl_4N_2O_2Sn$ (831.209): calcd. C 57.8, H 3.63, N 3.37; found C 60.05, H 3.70, N 3.45.

**Synthesis of Bis[*N*-(3-*tert*-butylsalicylidene)anilinato]dibenzyltin(IV) (3):** A solution of *N*-(3-*tert*-butylsalicylidene)aniline (1.34 g, 5.28 mmol in 50 mL of THF) was added dropwise to a stirred solution of NaH (270 mg, 11.4 mmol) in THF (10 mL) at 0 °C. The mixture was warmed to room temperature and stirred for 3 h. The resulting light orange solution was added to a stirred solution of $Cl_2Sn(CH_2C_6H_5)_2$ (980 mg, 2.64 mmol) in THF (20 mL) at 0 °C. The mixture was warmed to room temperature and stirred overnight. Removal of the solvent in vacuo gave a brown powder. The crude product was extracted with toluene; the solution was concentrated to 10 mL and stored at –20 °C. A yellow solid deposited overnight (1.55 g, 73%). $^{1}H$ NMR (400 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 7.99 (s, $^{3}J_{SnH}$ = 33.65 Hz, 2 H, N=C*H*), 7.89 (s, $^{3}J_{SnH}$ = 22.30 Hz, 1 H, N=C*H*), 7.69 (s, 1 H, N=C*H*), 5.25–7.27 (br. m, 32 H, Ar*H*), 2.4–2.7 (3dd, 8 H, $CH_2$Ph), 1.41 (s, 9 H, *t*Bu), 1.28 (s, 9 H, *t*Bu), 1.07 (s, 18 H, *t*Bu) ppm. $^{13}C$ NMR (100 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 174.3, 172.0, 169.0 (N=*C*H), 152.5–115.3 (Ar-*C*), 35.3, 35.1 (*C*-$CH_3$), 36.1, 34.8, 33.8 (Sn-$CH_2$Ph), 30.0, 29.6, 29.5 (C-$CH_3$) ppm. $^{119}Sn$ NMR (149 MHz, $CDCl_3$, 25 °C): $\delta$ = –456.5 (s), –457.9 (s) ppm. EI-MS: *m*/*z* (%) 714 (12) [$M^+ - CH_2Ph$], 683 (20), 460 (48), 343 (100). $C_{48}H_{50}N_2O_2Sn$ (805.64): calcd. C 71.56, H 6.25, N 3.47; found C 71.69, H 6.34, N 3.52.

**Generation of {Bis[*N*-(3,5-dichlorosalicylidene)anilinato]methyltin(IV)}$^+$ [MeB$(C_6F_5)_3]^-$ (1a):** Compound **1** (15 mg, 22 μmol) was dissolved in dry $CD_2Cl_2$ (0.5 mL). $B(C_6F_5)_3$ (11 mg, 22 μmol) was added to the yellow solution. The solution was analyzed by NMR spectroscopy at room temperature. $^{1}H$ NMR (400 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 8.54 (s, $^{3}J_{SnH}$ = 22.3 Hz, 2 H, N=C*H*), 6.9–7.7 (br. m, 14 H, Ar*H*), 1.04 (s, $^{2}J_{SnH}$ = 101.8 Hz, 3 H, Sn-$CH_3$), 0.42 (br. s, 3 H, -B$CH_3$) ppm. $^{13}C$ NMR (100 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 171.8 (N=*C*H), 119–150 (Ar*C*), 10.8 (B$CH_3^-$), 3.73 (Sn-$CH_3$) ppm. $^{119}Sn$ NMR (149 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = –394.0 (s) ppm. $^{19}F$ NMR (376 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = –168.2 (t, 2 F, *m*-F), –165.6 (t, 1 F, *p*-F), –133.6 (d, 2 F, *o*-F) ppm. The side-product $Sn(CH_3)_4$ was also identified.

**Generation of {Bis[*N*-(3,5-dichlorosalicylidene)anilinato]benzyltin(IV)}$^+$ (2a):** Compound **2** (15 mg, 18 μmol) was dissolved in dry $CD_2Cl_2$ (0.5 mL). $B(C_6F_5)_3$ (9 mg, 18 μmol) was added to the yellow solution. The resulting solution was analyzed by NMR spectroscopy at room temperature. Selected resonances $^{1}H$ NMR (400 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 1.04 (s, $^{2}J_{SnH}$ = 117.0 Hz, 2 H, Sn-

C$H_2$Ph), 6.5–7.7 (br. m, 14 H, Ar*H*), 8.47 (s, $^3J_{SnH}$ = 18.2 Hz, 2 H, N=C*H*) ppm. $^{119}$Sn NMR (149 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = –500.0 (s) ppm. $^{19}$F NMR (376 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = –169 to –123.6 ppm.

**Generation of {Bis[*N*-(3-*tert*-butylsalicylidene)anilinato]benzyltin(IV)}$^+$ [B(C$_6$F$_5$)$_4$]$^-$ (3a):** $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$ (25 mg, 27 μmol) was added to a yellow solution of compound **3** (22 mg, 27 μmol) in dry $CD_2Cl_2$ (0.5 mL). The resulting brown solution was analyzed by NMR spectroscopy at room temperature. $^1$H NMR (400 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 8.53 (s, $^3J_{SnH}$ = 14.92 Hz, 2 H, N=C*H*), 6.9–7.6 (br. m, 19 H, Ar*H*), 6.44 [d, $^4J_{SnH}$ = 33.75 Hz, 2 H, *o*-$CH_2(C_6H_5)$], 3.26 (s, $^2J_{SnH}$ = 118.84 Hz, 2 H, Sn-C$H_2$Ph), 1.34 (s, 18 H, *t*Bu) ppm. $^{13}$C NMR (100 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = 174.0 (N=*C*H), 124.2 [*o*-$CH_2(C_6H_5)$], 35.5 (*C*-$CH_3$), 32.0 (Sn-*C*H$_2$Ph), 29.8 (C-*C*H$_3$) ppm. $^{119}$Sn NMR (149 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = –448.7 (s) ppm. $^{19}$F NMR (376 MHz, $CD_2Cl_2$, 25 °C): $\delta$ = –168.0 (t, 2 F, *m*-F), –164.1 (t, 1 F, *p*-F), –133.6 (d, 2 F, *o*-F) ppm. $(C_6H_5)_3CH$ and $(C_6H_5)_3CCH_2Ph$ were also identified as side-products.

**Oligomerization Tests:** A typical oligomerization test was carried out in a 100-mL, magnetically stirred, glass flask, which was conditioned under dynamic vacuum, thermostated at 25 °C and then charged with a solution of the tin compound (30 μmol) and $[C(C_6H_5)_3]^+[B(C_6F_5)_4]^-$ or $B(C_6F_5)_3$ (30 μmol) in $ClC_6H_5$ or $CH_3C_6H_5$ (15 mL). Ethylene was fed continuously at a pressure of 1 atm; after 24 h, the reaction mixture was poured into acidified methanol (50 mL). The solution was treated with water and hexane (3 × 30 mL). The organic phase was dried with $Na_2SO_4$ and the solvents distilled off. An oily product was obtained; typically yields are of 200 mg. The products were analyzed by $^{13}$C NMR analysis; the oligomer structure was determined according to the literature.[22]

Additional oligomerization tests were performed as above, but adding into the oligomerization mixture 1 equiv. of one of the following compounds: 2,2,6,6-tetramethylpiperidine *N*-oxide, 2,6-di-*tert*-butylpyridine, dicumyl peroxide or dibenzoyl peroxide. Yields and products were unaffected by the presence of the additives. The products were analyzed by $^1$H and $^{13}$C NMR analysis; the oligomer structures were determined according to the literature.[22]

**Oligomerization Quenched with $CH_3OD$:** An oligomerization run was performed as described above, but at the end of the reaction time (24 h), a solution of $CF_3COOD$ (2 mL) and $CH_3OD$ (4 mL) was added to the reaction mixture. After two hours, the mixture was poured into methanol (50 mL). The solution was treated with water and hexane (3 × 30 mL). The organic phase was dried on $Na_2SO_4$ and the solvents stilled off. An oily product was obtained (yield: 130 mg). The product was analyzed by $^{13}$C, $^1$H, $^2$H NMR spectroscopy. Incorporation of deuterium into the oligomers was not detected.

**X-ray Crystallography. Crystal Data for 2:** Formula: $C_{40}H_{30}Cl_4N_2O_2Sn$, $FW$ = 831.15, triclinic, space group $P\bar{1}$ (no. 2), $Z$ = 1, $a$ = 9.429(4) Å, $b$ = 12.030(5) Å, $c$ = 8.630(3) Å, $\alpha$ = 90.11(3)°, $\beta$ = 99.52(3)°, $\gamma$ = 113.04(3)°, $V$ = 886.0(7) Å$^3$, $D_{calcd}$ = 1.558 g cm$^{-3}$, $\mu_{calcd}$ = 1.062 mm$^{-1}$.

Suitable crystals of **2** were selected and mounted in Lindemann capillaries under an inert atmosphere. Diffraction data were measured at room temperature with a Rigaku AFC7S diffractometer using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71069 Å). Data reduction was performed with the crystallographic package CrystalStructure.[23] The structure was solved by direct methods using the program SIR92[24] and refined by means of full-matrix least-squares based on $F^2$ using the program SHELXL97.[25] All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were positioned geometrically and included in structure factor calculations but not refined.

A total of 223 refinable parameters were finally considered. Maximum and minimum residual density were respectively 1.20 e Å$^{-3}$ and –0.89 e Å$^{-3}$. Final disagreement indices: $R_1$ = 0.037 for 4476 reflections with $F_o > 4\sigma(F_o)$, $wR_2$ = 0.091 for all 5170 data. Atomic coordinates, thermal factors, bond lengths and angles have been deposited with the Cambridge Crystallographic Data Centre (see below). ORTEP drawings were performed by means of the program ORTEP32.[26]

CCDC-641608 contains the supplementary crystallographic data (excluding structure factors) for compound **2**. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request.cif/.

**Supporting Information** (see also the footnote on the first page of this article): NMR characterization of compounds **1**, **2**, **3**, **1a**, **2a**, **3a** and of the ethylene oligomerization products.

## Acknowledgments

The authors are grateful to Dr. Patrizia Oliva for $^{119}$Sn NMR experiments. The authors acknowledge financial support by Università del Sannio (FAR 2006) and the University of Salerno (Finanziamento grandi e medie attrezzature) for the purchase of a new glove box.

[7] For the bis[*N*-(3-*tert*-butylsalicylidene)anilinato]dimethyltin(IV) compound (see ref.[2]) the isomerization barrier $\Delta G_c^{\neq}$ was calculated by using the Eyring equation $\Delta G_c^{\neq} = 4.576T_c[10.319 + \log T_c/K_c]$, where $K_c$ is the exchange rate constant at coalescence, given by $K_c = \pi\Delta\nu/\sqrt{2}$. $\Delta G_c^{\neq}$, calculated from $^1$H NMR, was 13.37 kcal mol$^{-1}$, in good agreement with the $\Delta G_c^{\neq}$ calculated from $^{119}$Sn NMR of 14.18 kcal mol$^{-1}$. In the case of compound **3** the $\Delta G_c^{\neq}$ for the isomerization should be significantly higher than these values. H. [14] In the aliphatic region of the $^{1}H$ NMR spectrum minor broad resonances were observed, together with minor signals set in the $^{19}F$ NMR spectrum. These fluorinated species could be attributed to borane species probably derived by aryl/alkyl group exchange reaction. These kinds of reaction have been well documented for some metal alkyl compounds ($MR_3$, M = Al, Ga, or $ZnR_2$), which reacted with $B(C_6F_5)_3$ or $[C(C_6H_5)_3]^+$-$[B(C_6F_5)_4]^-$, producing a variety of borane species $B(C_6F_5)_x$-$R_{3-x}$ ($x$ = 0–2) and a neutral metal corresponding compound $M(C_6F_5)_xR_{3-x}$ ($x$ = 0–2).
