Received 4 December 1989

$\text{Mg}^{2+}$ -loaded rat erythrocytes performed  $\text{Mn}^{2+}/\text{Mg}^{2+}$  antiport, which was nonspecifically stimulated by anions and cations.  $\text{Mn}^{2+}/\text{Mg}^{2+}$  antiport was shown to operate via the  $\text{Na}^+/\text{Mg}^{2+}$  antiporter because extracellular  $\text{Na}^+$  and  $\text{Mn}^{2+}$  inhibited the intracellular uptake of each other's ions competitively. Furthermore,  $\text{Mn}^{2+}/\text{Mg}^{2+}$  antiport and  $\text{Na}^+/\text{Mg}^{2+}$  antiport were identically inhibited by various amiloride derivatives.  $\text{Na}^+/\text{Mg}^{2+}$  antiport of chicken and human erythrocytes cannot perform  $\text{Mn}^{2+}/\text{Mg}^{2+}$  antiport although chicken erythrocytes took up more  $\text{Mn}^{2+}$  than rat erythrocytes.

$\text{Mn}^{2+}$  uptake;  $\text{Mg}^{2+}$  efflux; (Rat erythrocyte)

## 1. INTRODUCTION

In a preceding paper, Feray and Garay [1] described net  $\text{Mg}^{2+}$  efflux from  $\text{Mg}^{2+}$ -loaded rat erythrocytes in exchange for extracellular  $\text{Mn}^{2+}$ . This net  $\text{Mg}^{2+}$  efflux was probably performed by the  $\text{Na}^+/\text{Mg}^{2+}$  antiporter in the absence of extracellular  $\text{Na}^+$ .

Net  $\text{Mg}^{2+}$  efflux from erythrocytes can be performed by various  $\text{Mg}^{2+}$  transporting systems [2,3]: (i) by  $\text{Na}^+$ -dependent net  $\text{Mg}^{2+}$  efflux operating via  $\text{Na}^+/\text{Mg}^{2+}$  antiport [4,5]; (ii) by  $\text{Na}^+$ -independent net  $\text{Mg}^{2+}$  efflux in combination with  $\text{Cl}^-$  efflux for charge compensation. This  $\text{Mg}^{2+}$  efflux takes place in sucrose medium and is inhibited by  $[\text{Cl}^-]_0$  and SITS [2,3]; (iii) in choline-Cl or KCl medium another net  $\text{Mg}^{2+}$  efflux occurs which is independent of  $[\text{Na}^+]_0$  and is not inhibited by  $[\text{Cl}^-]_0$  or SITS [2,3]. Therefore, we investigated whether other  $\text{Mg}^{2+}$  efflux systems can exchange extracellular  $\text{Mn}^{2+}$  for intracellular  $\text{Mg}^{2+}$  from  $\text{Mg}^{2+}$ -loaded erythrocytes.

## 2. MATERIALS AND METHODS

Blood was taken by heart puncture from anaesthetized rats (50 mg/kg Nembutal s.c.) and by venous puncture from chicken or human (J.V.) by means of a heparinized syringe and centrifuged at  $1000 \times g$  for 10 min. The plasma and buffy coat were aspirated and the red cells were washed twice with 150 mM KCl.

**Correspondence address:** T. Günther, Institute of Molecular Biology and Biochemistry, Free University of Berlin, Arnimallee 22, D-1000 Berlin 33, FRG

**Abbreviations:**  $[\text{Na}^+]_0$ ,  $[\text{Cl}^-]_0$ ,  $[\text{Mn}^{2+}]_0$ , extracellular concentration of  $\text{Na}^+$ ,  $\text{Cl}^-$ , or  $\text{Mn}^{2+}$ ; TCA, trichloroacetic acid; SITS, 4-acetamido-4'-isothiocyantostilbene-2,2'-disulfonic acid

The cells were loaded with  $\text{Mg}^{2+}$  by incubating a 10% cell suspension for 30 min at  $37^\circ\text{C}$  in KCl medium (in mM: 140 KCl, 50 sucrose, 5 glucose, 30 Hepes-Tris, pH 7.4) with the addition of 12 mM  $\text{MgCl}_2$  and 6  $\mu\text{M}$  A23187 (dissolved in dimethyl sulfoxide). For removal of the ionophore, the cells were incubated 4 times in KCl- $\text{MgCl}_2$  medium plus 1% bovine serum albumin for 10 min at  $37^\circ\text{C}$ . The KCl- $\text{MgCl}_2$  medium was removed by washing the cells twice with sucrose, KCl, NaCl or choline-Cl medium. The sucrose medium contained (in mM): 350 sucrose, 5 glucose, 30 Hepes-Tris, pH 7.4. NaCl or choline-Cl medium was prepared by substitution of KCl in KCl medium by 140 mM NaCl or 140 mM choline-Cl. Under these conditions of  $\text{Mg}^{2+}$ -loading intracellular  $\text{Mg}^{2+}$  content of rat, chicken and human erythrocytes amounted to 20, 17.5, and 20 mmol/l cells.

$\text{Mg}^{2+}$  efflux was measured by reincubation of a 10% cell suspension at  $37^\circ\text{C}$  in sucrose, KCl, choline-Cl or NaCl medium, as indicated.

In some efflux experiments, the cations or anions were substituted by positively or negatively charged ampholine. Ampholine (1809006), pH 2.5-4, or ampholine (1809046), pH 9-11 (Pharmacia, Bromma, Sweden), were neutralized to pH 7.4 with 1 N KOH or 1 N NaOH or 1 N HCl. Aliquots of the neutralized ampholine were added to the media instead of KCl or NaCl to yield 145 mM  $\text{K}^+$ ,  $\text{Na}^+$  or  $\text{Cl}^-$ .

At the beginning of reincubation and after 30 min, 0.5 ml aliquots of the cell suspension were centrifuged for 1 min at  $10\,000 \times g$ . For  $\text{Mg}^{2+}$  determination, 100  $\mu\text{l}$  supernatant was diluted with 1 ml 10% TCA/0.175%  $\text{LaCl}_3$  and  $\text{Mg}^{2+}$  was measured by atomic absorption spectrophotometry (Philips, SP 9). An aliquot of the supernatant was taken for the determination of hemoglobin by means of the cyanmethemoglobin method. For measuring  $\text{Mn}^{2+}$ -induced  $\text{Mg}^{2+}$  efflux,  $\text{MnCl}_2$  was added to the reincubation media, as indicated.

For measuring intracellular  $\text{Mg}^{2+}$ ,  $\text{Mn}^{2+}$  and  $\text{Na}^+$  content, the sedimented cells were washed twice with 150 mM KCl and hemolyzed by adding 750  $\mu\text{l}$   $\text{H}_2\text{O}$ . 50  $\mu\text{l}$  of the hemolysate were taken for determination of hemoglobin, the rest was deproteinized by addition of 50  $\mu\text{l}$  75% TCA and centrifuged.

$\text{Mg}^{2+}$  and  $\text{Mn}^{2+}$  content was measured by atomic absorption spectrophotometry after dilution with 10% TCA/0.175%  $\text{LaCl}_3$ .  $\text{Na}^+$  content was measured after addition of LiCl by flame photometry (KliNa-Flame, Beckman). Cellular  $\text{Mg}^{2+}$  content was taken to correct  $\text{Mg}^{2+}$  efflux for hemolysis. Cellular  $\text{Mn}^{2+}$  and  $\text{Na}^+$  content was taken to determine  $\text{Mn}^{2+}$  influx or  $\text{Na}^+$  influx.

Amiloride and its four analogs (see legend fig.3) were synthesized for this study by methods described earlier [6].

### 3. RESULTS AND DISCUSSION

As shown in table 1,  $\text{Mn}^{2+}$ -induced  $\text{Mg}^{2+}$  efflux was low in sucrose medium but occurred to a high degree in KCl or choline-Cl medium.

These results indicate that  $\text{Mn}^{2+}$ -dependent net  $\text{Mg}^{2+}$  efflux was activated in salt-containing media.  $\text{Mn}^{2+}$ -induced  $\text{Mg}^{2+}$  efflux at 0 mM KCl amounted to 0.8 mmol  $\text{Mg}^{2+}$ /l cells  $\times$  30 min and increased linearly with KCl concentration to 4.2 mmol/l cell  $\times$  30 min at 150 mM KCl (fig.1).

Since  $\text{Mn}^{2+}$ -induced  $\text{Mg}^{2+}$  efflux was the same in KCl and choline-Cl medium (table 1), this transport system is not specifically dependent on cations. Therefore, we tested anion specificity. As can be seen from table 2,  $\text{Mn}^{2+}$ -induced net  $\text{Mg}^{2+}$  efflux was also not specifically dependent on anions. The role of either cations or anions was tested with ampholines (table 3).

In the presence of 145 mM  $\text{Cl}^-$ , compensated by polycationic ampholine, and in the presence of 145 mM  $\text{K}^+$ , compensated by polyanionic ampholine,  $\text{Mn}^{2+}$  did

Fig.1. Stimulation of  $\text{Mn}^{2+}$ -induced  $\text{Mg}^{2+}$  efflux from  $\text{Mg}^{2+}$ -loaded rat erythrocytes by KCl. Sucrose of sucrose medium was isosmotically substituted by KCl. Difference of  $\text{Mg}^{2+}$  efflux between tests without and with the addition of 0.5 mM  $\text{MnCl}_2$  at various KCl concentrations was plotted.

Table 2

Effects of various anions and cations on  $\text{Mn}^{2+}$ -dependent  $\text{Mg}^{2+}$  efflux from rat erythrocytes

not significantly induce net  $\text{Mg}^{2+}$  efflux. From this result it can be concluded that small cations and small anions must be present simultaneously in the medium to permit  $\text{Mn}^{2+}$ -induced  $\text{Mg}^{2+}$  efflux.

$\text{Na}^+/\text{Mg}^{2+}$  antiport was also active in a medium with 150 mM  $\text{Na}^+$  compensated by polyanionic ampholine (table 3) and thus not dependent on the presence of small anions in the medium. The meaning of this result is not clear.

As indicated in table 1,  $\text{Mg}^{2+}$  efflux in NaCl medium was reduced by  $[\text{Mg}^{2+}]_0$ . Therefore, this relationship between  $[\text{Na}^+]_0$ ,  $\text{Mg}^{2+}$  efflux and  $\text{Mn}^{2+}$  influx was investigated in greater detail.

$\text{Mn}^{2+}$  was taken up in  $\text{Mg}^{2+}$ -unloaded cells, incubated in sucrose, NaCl or KCl medium (table 4). However, in  $\text{Mg}^{2+}$ -loaded cells,  $\text{Mn}^{2+}$  uptake was 3 times higher in sucrose and 9 times higher in NaCl and KCl medium than in unloaded cells (table 4).  $\text{Mn}^{2+}$  up-

Mean of two experiments

<sup>a</sup> In Mg<sup>2+</sup>-unloaded cells no significant Mg<sup>2+</sup> efflux was measured

take in Mg<sup>2+</sup>-unloaded cells was not correlated to efflux of Mg<sup>2+</sup>. In Mg<sup>2+</sup>-loaded cells incubated in sucrose medium Mn<sup>2+</sup>-induced Mg<sup>2+</sup> efflux was approximately the same as Mn<sup>2+</sup> uptake. However, in KCl medium Mn<sup>2+</sup>-induced Mg<sup>2+</sup> efflux exceeded Mn<sup>2+</sup> uptake. These results indicate that there are two mechanisms for Mn<sup>2+</sup> uptake. (i) Mn<sup>2+</sup> uptake into unloaded cells, which is not related to Mg<sup>2+</sup> efflux. Its mechanism has not yet been defined. (ii) Mn<sup>2+</sup> uptake into Mg<sup>2+</sup>-loaded cells is accompanied by an additional efflux of Mg<sup>2+</sup>. From the quantitative relationship between the Mg<sup>2+</sup> and Mn<sup>2+</sup> fluxes it can be assumed that there was an Mn<sup>2+</sup>/Mg<sup>2+</sup> antiport in sucrose medium. However, in KCl medium, Mg<sup>2+</sup> efflux exceeded Mn<sup>2+</sup> uptake. Therefore, also in KCl medium a major part of Mg<sup>2+</sup> efflux may occur in exchange for extracellular Mn<sup>2+</sup>, as found by Feray and Garay [1]. However, Mn<sup>2+</sup> may cause an additional efflux of Mg<sup>2+</sup> in KCl medium.

Fig.2. Lineweaver-Burk plot of Mn<sup>2+</sup> influx into Mg<sup>2+</sup>-loaded rat erythrocytes. (A) [Na<sup>+</sup>]<sub>0</sub> = 150 mM; (B) [Na<sup>+</sup>]<sub>0</sub> = 30 mM (NaCl of NaCl medium was isoosmotically substituted by KCl).

When Mn<sup>2+</sup>/Mg<sup>2+</sup> antiport is performed via the Na<sup>+</sup>/Mg<sup>2+</sup> antiport system, extracellular Na<sup>+</sup> should be a competitive inhibitor of net Mn<sup>2+</sup> uptake. As shown in fig.2, extracellular Na<sup>+</sup> inhibited Mn<sup>2+</sup> uptake competitively, and vice versa, Na<sup>+</sup> uptake into Mg<sup>2+</sup>-loaded rat erythrocytes was competitively inhibited by [Mn<sup>2+</sup>]<sub>0</sub> (not shown).

To elucidate the problem whether the Na<sup>+</sup>/Mg<sup>2+</sup> antiporter is functioning in Mn<sup>2+</sup>/Mg<sup>2+</sup> antiport, we tested inhibition of Mn<sup>2+</sup>-induced Mg<sup>2+</sup> efflux by various amiloride derivatives.

As shown in fig.3, Mn<sup>2+</sup>-induced Mg<sup>2+</sup> efflux was inhibited by various amiloride derivatives. The order of potency of inhibition was identical to the inhibition of

Fig.3. Inhibition of Mn<sup>2+</sup>-induced Mg<sup>2+</sup> efflux from Mg<sup>2+</sup>-loaded rat erythrocytes by various amiloride derivatives. KCl medium with 1 mM MnCl<sub>2</sub> was taken. 100% amounted to 5.93 mmol Mg<sup>2+</sup>/l cells × 30 min. (1) Amiloride; (2) 5-(N-ethyl-N-isopropyl)amiloride; (3) 5-(N-methyl-N-isobutyl)amiloride; (5) 5-(N-ethyl-N-4-chlorobenzyl)amiloride; (7) 5-(N-methyl-N-4-hydroxyphenyl)amiloride. The amiloride derivatives were dissolved in dimethyl sulfoxide (DMSO). The final DMSO concentration in the tests amounted to 1%. 100% values were run with 1% DMSO. Same numbering of amiloride derivatives as in [7].

Fig.4. Stimulation of  $\text{Mg}^{2+}$  efflux by various divalent cations.  $\text{Mg}^{2+}$ -loaded rat erythrocytes were incubated in choline-Cl medium with the addition of  $\text{MnCl}_2$ ,  $\text{CoCl}_2$ ,  $\text{ZnCl}_2$  and  $\text{CdCl}_2$  as indicated.

$\text{Na}^+/\text{Mg}^{2+}$  antiport by the same amiloride derivatives [7].  $\text{Mn}^{2+}$  uptake was simultaneously inhibited. The order of potency of inhibition of  $\text{Mn}^{2+}$  uptake by the amiloride derivatives was the same as the inhibition of  $\text{Mg}^{2+}$  efflux (data not shown), again indicating  $\text{Mn}^{2+}/\text{Mg}^{2+}$  antiport.

These results indicate that  $[\text{Mn}^{2+}]_0$ -induced  $\text{Mg}^{2+}$  efflux is performed via the  $\text{Na}^+/\text{Mg}^{2+}$  antiporter. This mechanism is also operating in sucrose medium although to a lower degree because  $\text{Mn}^{2+}/\text{Mg}^{2+}$  antiport is nonspecifically stimulated by small anions and cations (fig.1).

This  $\text{Mn}^{2+}/\text{Mg}^{2+}$  exchange system in rat erythrocytes is not specific for  $\text{Mn}^{2+}$ . As shown in fig.4,  $\text{Co}^{2+}$ ,  $\text{Zn}^{2+}$  and  $\text{Cd}^{2+}$  also induced net  $\text{Mg}^{2+}$  efflux from  $\text{Mg}^{2+}$ -loaded rat erythrocytes with decreasing effectivity in this order. This order corresponds to

Table 6  
Effect of  $[\text{Mn}^{2+}]_0$  on  $\text{Mg}^{2+}$  efflux and  $\text{Mn}^{2+}$  influx of  $\text{Mg}^{2+}$ -loaded human erythrocytes

Medium	$\text{MnCl}_2$ (mM)	$\text{Mg}^{2+}$ efflux (mmol/l cells $\times$ 30 min)	$\text{Mn}^{2+}$ influx

the increase of stability constants of these metal ions with various ligands (e.g. glycinate, oxalate, malonate [8]). Other divalent cations as  $\text{Ba}^{2+}$ , and  $\text{Sr}^{2+}$  were ineffective (data not shown).

Chicken erythrocytes possess an active  $\text{Na}^+/\text{Mg}^{2+}$  antiport [3,4,9] with similar properties as the  $\text{Na}^+/\text{Mg}^{2+}$  antiport of rat erythrocytes [5,7]. However, in chicken erythrocytes, extracellular  $\text{Mn}^{2+}$  did not induce (but inhibited) net  $\text{Mg}^{2+}$  efflux, although chicken erythrocytes took up more  $\text{Mn}^{2+}$  than rat erythrocytes (table 5).

Also in human erythrocytes  $\text{Mn}^{2+}$  did not induce  $\text{Mg}^{2+}$  efflux from  $\text{Mg}^{2+}$ -loaded cells but caused inhibition of  $\text{Mg}^{2+}$  efflux (table 6). Therefore,  $\text{Na}^+/\text{Mg}^{2+}$  antiport in  $\text{Mg}^{2+}$ -loaded chicken and human erythrocytes may be performed by proteins with different structures compared to rat erythrocytes.

Table 5
