#### Summary

The 1-deoxy-1-nitro-*D*-manno-pyranose **4** was transformed into the nitroolefin **5** and hence into the anomeric 1,2-dideoxy-1-nitro-3,4,6-tri-*O*-benzyl-*D*-arabino-hexopyranoses (**3a** and **3b**; cf. the *Scheme*). Conformational analysis of 1-benzyloxy-2-nitroethane (**6**) by <sup>1</sup>H-NMR spectroscopy (*Fig. 2*) showed the synclinal conformation to be more stable than the antiperiplanar one by about 1.4 kcal/mol (attractive *gauche*-effect). This *gauche*-effect favours the 1-deoxy-1-nitro-2,3,4,6-tetra-*O*-benzyl- $\beta$ -*D*-manno-hexopyranose (**1b**) possessing an equatorial nitro group, which is, however, qualitatively the less stable anomer. The relative concentrations of the anomers of **1** and **3**, respectively, were determined by <sup>1</sup>H-NMR spectroscopy after base catalyzed equilibration at 37° in CHCl<sub>3</sub>-solution (*Table*). Anomeric effects for the nitro group of approximately 2.4 kcal/mol in **3** and of approximately 3.4 kcal/mol in **1** were calculated.

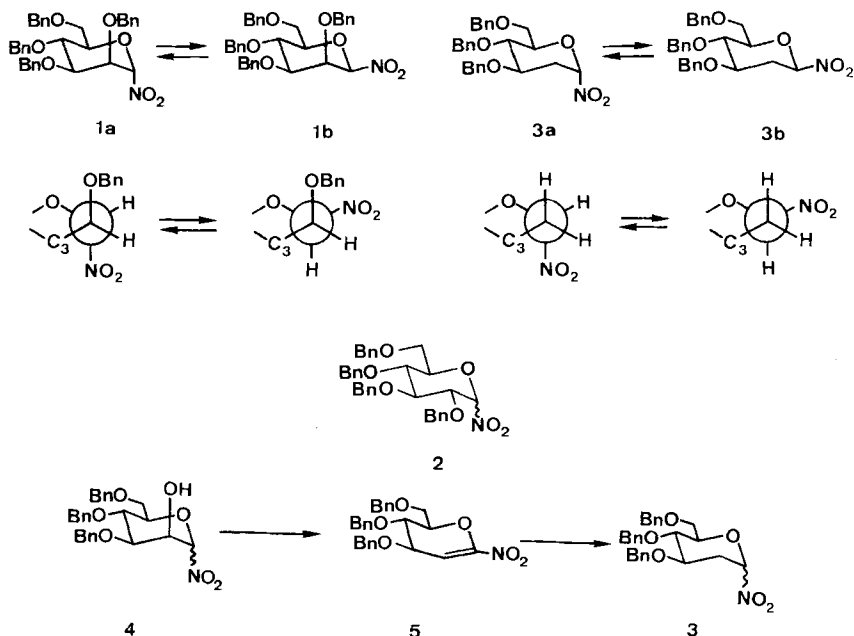

---

**Introduction.** – Protected and partially protected 1-nitro-1-deoxyaldoses are readily available and preparatively useful new sugar derivatives [1–3]. They anomerize under slightly acidic or basic conditions to yield predominantly the anomer with an axial nitro group [2], qualitatively indicating a normal anomeric effect (cf. [4–7]) of this group. We report now the first determination of the anomeric effect of the nitro group in the tetrabenzyl-*manno*-pyranoses **1** and in the corresponding 2-deoxypyranoses **3**<sup>2)</sup>. The anomeric 1,2-dideoxy-1-nitropyranoses **3** were prepared by NaBH<sub>4</sub>-reduction [8] of the 1-nitroglycol **5**, which was easily obtained by methanesulfonation of the known 2-hydroxy nitro-ether **4** [1] followed by  $\beta$ -elimination. Since the '*A*-value' (cf. [5] [9]) of the nitro group is known [17], the determination of the equilibrium between the anomers of **3** leads to the anomeric

<sup>1)</sup> 4<sup>th</sup> Communication: [1].

<sup>2)</sup> The corresponding 1-deoxy-1-nitro-2,3,4,6-tetra-*O*-benzyl-*D*-glucopyranoses (**2**) decomposed partially in the course of the base-catalyzed anomerization [2].

effect of the nitro group in **3**. In the case of the tetrabenzyl-*D*-manno-pyranoses **1**, however, one must also consider the relative orientation of the 1-nitro and the 2-benzyloxy group, which are antiperiplanar in the  $\alpha$ -*D*-anomer **1a** and synclinal in the  $\beta$ -*D*-anomer **1b** (Scheme). A recent study of nitroalcohols has demonstrated that the synclinal conformation is qualitatively preferred [10], contradicting earlier suggestions [11]. In order to obtain quantitative results for the anticipated analogous preference for a synclinal orientation of the nitro- and the benzyloxy group we analyzed the conformations of 1-benzyloxy-2-nitroethane (**6**) obtained from benzyl alcoholate and nitroethylene.

**Conformational Analysis of 1-Benzyloxy-2-nitroethane (6).** – The vicinal H,H coupling constants in 1,2-disubstituted ethanes  $XCH_2CH_2Y$  can be used to determine the relative rotamer populations in these compounds. The conformers and coupling constants shown in Fig. 1 are considered. The differentiation between

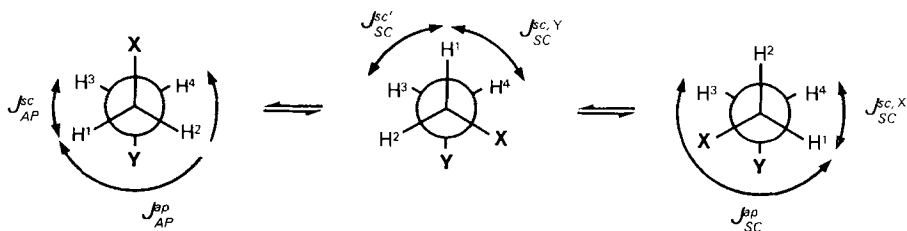

Fig. 1: Coupling constants used in the conformational analysis of **6** (AP (antiperiplanar) and SC (synclinal) refer to the groups X and Y, ap and sc to the H-atoms)

$J_{SC}^{sc'}$ ,  $J_{SC}^{sc,X}$ , and  $J_{SC}^{sc,Y}$  takes into account the fact that the substituent effect on vicinal coupling constants, which depends on the electronegativity of substituents, is largest if they are in an antiperiplanar position [12] [13] to one of the coupled nuclei. For the observable coupling constants one obtains:

$$J(H^1, H^3) = n_{AP} \cdot J_{AP}^{sc} + n_{SC} \cdot \frac{1}{2} (J_{SC}^{sc'} + J_{SC}^{ap}) \quad (1)$$

$$J(H^1, H^4) = n_{AP} \cdot J_{AP}^{ap} + n_{SC} \cdot \frac{1}{2} (J_{SC}^{sc,Y} + J_{SC}^{sc,X}), \quad (2)$$

where  $n_{AP}$  and  $n_{SC}$  denote the *AP*- and *SC*-rotamer-populations, respectively ( $n_{AP} + n_{SC} = 1$  and  $n_{SC}/n_{AP} = 2 \cdot \exp\{-(E_{AP} - E_{SC})/RT\}$ ). The application of *Equations 1* and *2* to the evaluation of  $n_{AP}$  requires knowledge of the coupling constants assigned to the fixed orientations of coupled nuclei and substituents. These coupling constants can be estimated through the set of equations derived by *Abraham & Gatti* [14] under the assumption that  $J_{SC}^{sc,X} = J_{SC}^{sc,Y} = J_{SC}^{sc}$ . Then we obtain:

$$J(H^1, H^3) = n_{AP} [1.35 + 0.63(E_X + E_Y)] + n_{SC} [13.46 - 1.02(E_X + E_Y)] \quad (3)$$

$$J(H^1, H^4) = n_{AP} [18.07 - 0.88(E_X + E_Y)] + n_{SC} [8.94 - 0.94(E_X + E_Y)], \quad (4)$$

with  $E_X, E_Y$  = electronegativity of X and Y according to *Huggins* [15]. Although *Eqn. 3* and *4* should provide the same value for  $n_{AP}$ , the value derived from  $J(H^1, H^4)$  is generally preferred [16] since  $J(H^1, H^4)$  is more strongly dependent on changes in rotamer populations than  $J(H^1, H^3)$ . The *Huggins* electronegativities for the substituents  $\text{PhCH}_2\text{O}$  and  $\text{NO}_2$ , however, are not known, but the application of *Eqn. 3* and *4* allowed us to calculate  $(E_X + E_Y)$  and  $n_{AP}$ .

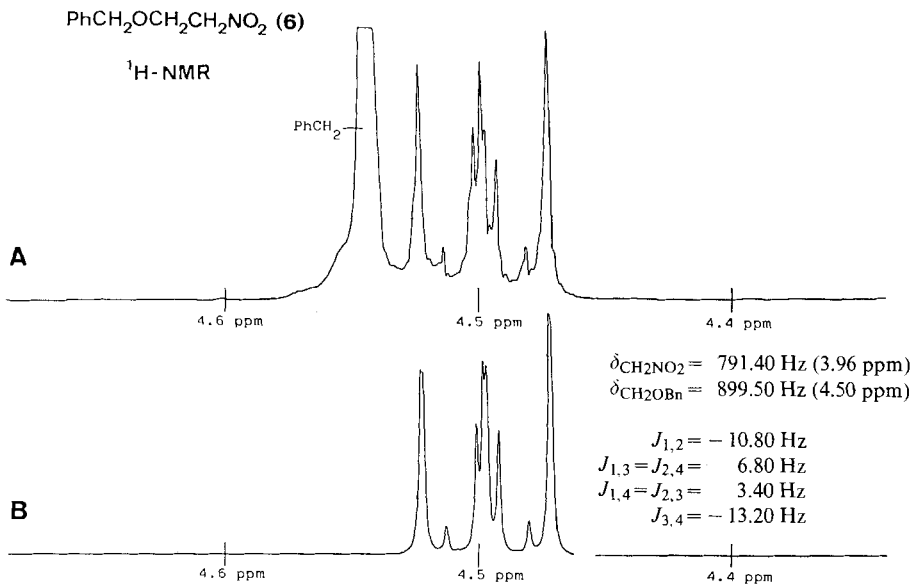

Fig. 2. 200-MHz-<sup>1</sup>H-NMR spectrum ( $\text{CDCl}_3$ ) of the  $\text{CH}_2\text{NO}_2$  group of **6** at 308 K. A) experimental, B) calculated spectrum.

From  $^1\text{H-NMR}$  spectrum of **6** at 200 MHz the values of chemical shifts and coupling constants were extracted by iterative analysis of the  $AA'XX'$ -type spectrum using a LAOCOON program (Fig. 2). The assignment of  $J_{AX} = 6.80$  Hz to  $J(\text{H}^1, \text{H}^3)$  and  $J_{AX'} = 3.40$  Hz to  $J(\text{H}^1, \text{H}^4)$  is unambiguous in our case since the reverse assignment puts the 3.40 Hz coupling outside the calculated range (Eqn. 3) of  $J(\text{H}^1, \text{H}^3)$ . The correct assignment was confirmed by analyzing spectra taken at different temperatures. Solving Eqn. 3 and 4 we obtained:

$$n_{AP} = 0.06 (= 6\%), (E_X + E_Y) = 6.45^3$$

The population analysis was also carried out by use of a Karplus-Conroy-type approximation<sup>4)</sup> of the coupling constants contained in Eqn. 1 and 2. Varying the angle  $\varnothing$  between the substituents X and Y from 60 to 65° we obtained a value of  $n_{AP}$  between 7 and 13%. A value for  $n_{AP}$  of  $9 \pm 4\%$  was adopted for the calculation of the conformational free energy. This value covers the results of both approaches and does not overemphasize the attractive *gauche*-effect.

**Equilibration of the Anomers.** – Two samples each of **1** and **3**, characterized by different concentrations ( $C_0$ ) of anomers were equilibrated in  $\text{CHCl}_3$ <sup>5)</sup> at 37° in the presence of a weakly basic ion-exchange resin (Amberlite IRA 193). The progress of equilibration was periodically checked by  $^1\text{H-NMR}$  spectroscopy. The relative concentrations of the anomers at equilibrium ( $C_{eq}$ ) were measured by integration of the H–C(1)-signals (200-MHz- $^1\text{H-NMR}$  spectra;  $\delta = 5.57$  ppm (**1a**); 5.17 ppm (**1b**); 5.58 ppm (**3a**) and 5.25 ppm (**3b**)), and the results are given in the Table.

Table. Equilibration of **1a, b** and of **3a, b**

Compound	$C_0$ (%) <i>a</i> -D:β-D	$C_{eq}$ (%) <i>a</i> -D:β-D	$\Delta G^\circ$ (kcal/mol)	Conditions (mg of compound/mg resin/time)
<b>1</b>	11.9:88.1	93.2:6.8	1.62	31/31/159 h
	>95:5	94.0:6.0	1.70	48/48/159 h
<b>3</b>	48.2:51.8	91.7:8.3	1.48	65/65/370 h
	>95:5	93.7:6.3	1.67	70/70/377 h

**Calculation of the Anomeric Effect.** – The anomeric effect of the nitro group in **3** is given by the sum of the 'A-value' of the nitro group and the  $\Delta G^\circ$ -value characterizing the equilibrium between the *a*-D- and β-D-anomers [5] [7]. An 'A-value' of 0.78 kcal/mol for the nitro group has been determined by Trager & Huitric [17] by equilibration of 1-(*t*-butyl)-4-nitrocyclohexane under the same conditions as we have used for the equilibration of **1** and **3**. From the  $\Delta G^\circ$ -values for the equilibrium

<sup>3)</sup> As a second mathematical solution one obtains  $n_{AP} = 0.30$  and  $(E_X + E_Y) = 13.31$  which is clearly outside the possible range of electronegativities.

<sup>4)</sup> The following equation was used:

$$J = J_0 (1 + 0.83 \cos 2\theta - 0.17 \cdot \cos \theta); \theta = \text{dihedral angle between coupled protons.}$$

<sup>5)</sup> In  $\text{CDCl}_3$  a partial H,D-exchange of H–C(1) occurred. The equilibration of **3** was discontinued after 377 h (slow decomposition). For details see *Exper. Part*.

**3a** = **3b** (1.48 and 1.67 kcal/mol, respectively; see the *Table*) one thus obtains an anomeric effect for the nitro group in **3** of 2.26 and 2.45 kcal/mol, respectively, *i.e.* of approximately 2.35 kcal/mol. The anomeric effect for the nitro group in **1** can be calculated only approximately since a small error in the conformer population of 1-benzyloxy-2-nitroethane is strongly reflected in the relative energy of the two conformers. The mean value  $n_{AP} = 9 \pm 4\%$  for the antiperiplanar rotamer population corresponds to  $\Delta G_{(AP,SC)}^{308K} = 1.42$  kcal/mol in favour of the synclinal conformers. Hence a free energy difference of 1 kcal/mol favouring the  $\beta$ -D anomer of **1** is deduced. From this value, the 'A-value' of the nitro group and the  $\Delta G^\circ$ -values for the equilibrium **1a** = **1b** ( $\Delta G^\circ = 1.62$  and 1.70 kcal/mol, respectively; see the *Table*) one obtains an anomeric effect of about 3.4 kcal/mol for the nitro group in **1**. The stronger anomeric effect of the nitro group in **1** is in keeping with the known influence on the anomeric effect of an (axial!) 2-alkoxy group [7] [18–20].

Financial support by the *Swiss National Science Foundation* and by *Sandoz Ltd.*, Basel, is gratefully acknowledged.

### Experimental Part

*General Remarks.* See [21].

**3, 4, 6-Tri-O-benzyl-1, 2-dideoxy-1-nitro-D-arabino-hex-1-enopyranose (5).** To a solution of the crude 1-deoxy-1-nitromannose **4** [1] (obtained from 901 mg (2 mmol) of 3,4,6-tri-*O*-benzyl-mannose [22]) in 12 ml of anhyd. Et<sub>2</sub>O were added at 0° 388  $\mu$ l (5 mmol) of methanesulfonyl chloride and 1.11 ml (8 mmol) of Et<sub>3</sub>N. The solution was warmed to r.t. and stirred for 45 min. TLC (AcOEt/toluene 1:9) showed the transformation of **4** ( $R_f$  0.23) into a less polar product ( $R_f$  0.58). The solution was poured into 20 ml of 1M NaHCO<sub>3</sub>, and the org. layer was washed with brine, dried (MgSO<sub>4</sub>) and concentrated. Chromatography of the yellow crude product on 100 g of silica gel (AcOEt/hexane 1:9) gave 538 mg (58%) of **5** as a pale yellow syrup.  $[a]_D = -1.9^\circ$  ( $c = 1.4$ ). C<sub>9</sub>H<sub>11</sub>NO<sub>3</sub> (181.19) Calc. C 59.66 H 6.12 N 7.73% Found C 59.55 H 6.31 N 7.92%

*Equilibration of 1 and 3*. A tube containing a magnetic stirring bar was charged with equal quantities (31–70 mg, see *Table*) of the 1-deoxy-1-nitroaldose and Amberlite IRA 93 (free base, *Fluka*). CHCl<sub>3</sub> (0.5 ml) was added, and the tube was sealed under vacuum. The solution was stirred at 37° in a thermostated bath. The progress of the equilibration was checked by <sup>1</sup>H-NMR of the residue obtained by filtration and evaporation of the CHCl<sub>3</sub> at r.t. The equilibration was continued under the same conditions, and the concentration of anomers at the equilibrium was determined by 200-MHz <sup>1</sup>H-NMR spectroscopy.

Equilibration of 30.7 mg of **1a/1b** (11.9:88.1) gave, after 159 h, 30 mg of **1a/1b** (93.2:6.8). Equilibration of 48 mg of **1a/1b** (96.8:3.2) gave after 159 h, 47 mg of **1a/1b** (94.0:6.0). The two samples were combined and chromatographed on prep. TLC-plates (silica gel, AcOEt/hexane 1:3) giving back 71 mg (90%) of **1**.

Equilibration of 65 mg of **3a/3b** (48.2:51.8) gave, after 370 h, 64 mg of **3a/3b** (91.7:8.3). Equilibration of 70 mg of pure **3a** gave after 377 h, 68 mg of **3a/3b** (93.7:6.3). The samples were then chromatographed on 6 g of silica gel (flash chromatography, Et<sub>2</sub>O/hexane 1:4) giving 113 mg (84%) of **3**.
