# 99. Complexes of $\mathbf{2 , 2}, \mathbf{2}^{\prime \prime}$-Nitrilotriphenol 

## Part IV

# Cage Compounds with Phosphorus(III) and Phosphorus(V) 

by Edgar Müller ${ }^{1}$ ) and Hans-Beat Bürgi $\left.{ }^{2}\right)^{*}$<br>Laboratorium für anorganische Chemie, ETH, CH-8092 Zürich

(31. III. 87)

The ligand $2,2^{\prime}, 2^{\prime \prime}$-nitrilotriphenol reacts with $\mathrm{P}(\mathrm{III})$ and $\mathrm{P}(\mathrm{V})$ compounds to form corresponding phosphorus complexes. Syntheses and NMR data of $2,2^{\prime}, 2^{\prime \prime}$-nitrilotriphenyl phosphite (II), $2,2^{\prime}, 2^{\prime \prime}$-nitrilotriphenyl phosphate (III) and of a hydrolysis product of II, 2, $2^{\prime}-[N$-(2-hydroxyphenyl)imino]diphenyl phosphonate (IV), are reported, as well as crystal structures of II and IV. Phosphite II shows a bicycloundecane framework; no N $\cdots$ P interaction is present. The phosphonate IV shows two coordinated and one dangling phenol group; the N -atom does not interact with the P-atom. Strong acids protonate II as well as III to form cations: in these, NMR evidence indicates coordination of the N -atom to the P -atom.

Introduction. - In a series of preceding papers, we reported on structure and reactivity
 [2]. In the present paper, we describe some phosphorus compounds of $2,2,2^{\prime \prime}$-nitrilotriphenolate.

I

II

III

IV

[^0]Some years ago, Verkade and coworkers [3] reported on a tricyclic phosphorus cage compound I, called phosphatrane, which can formally be regarded as a protonated complex of $\mathrm{P}(\mathrm{III})$ with $2,2^{\prime}, 2^{\prime \prime}$-nitrilotriethanol. Analogous complexes of $\mathrm{P}(\mathrm{V})$ were reported by the same research group [4-6]. The protonated phosphatrane I was shown to have a rather short $\mathbf{P}-\mathrm{H}$ distance $\left(1.35 \AA\right.$ ) but a lower ${ }^{31} \mathrm{P},{ }^{1} \mathrm{H}$-coupling constant ( 791 Hz ) in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum than noncyclic protonated phosphite esters (e.g. $\left(\mathrm{CH}_{3} \mathrm{O}\right)_{3} \mathrm{PH}^{+}$: 826 Hz [3]). These apparently controversial findings were explained as a consequence of the trigonal-bipyramidal (tbp) structure of $\mathbf{I}$. The unprotonated presursor of (I) could never be crystallized, as it polymerized upon concentration of its solutions [6].

Using the more rigid $2,2^{\prime}, 2^{\prime \prime}$-nitrilotriphenolate ligand instead of the $2,2^{\prime}, 2^{\prime \prime}$-nitriloethanolate, we hoped to obtain the unprotonated phosphatrane precursor II, in order to elucidate its structure and to answer the question whether significant $\mathrm{N} \cdots$ P interaction is present in an unprotonated phosphatrane or not.

The bicyclic compound II was synthesized straightforwardly according to Eqn.1.

$$
\begin{equation*}
\mathrm{N}\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{OH}\right)_{3}+\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~N}\right)_{3} \mathrm{P} \longrightarrow \mathrm{~N}\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{O}_{3}\right) \mathrm{P}+3\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH} \tag{1}
\end{equation*}
$$

No high-dilution techniques were required. The corresponding phosphate III was obtained according to Eqn. 2

$$
\begin{equation*}
\mathrm{N}\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{OH}\right)_{3}+\mathrm{O}=\mathrm{PCl}_{3}-\frac{3 \mathrm{Et}_{3} \mathrm{~N}}{\mathrm{THF}} \mathrm{~N}\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{O}_{3}\right) \mathrm{P}=\mathrm{O}+3 \mathrm{Et}_{3} \mathrm{NHCl} \tag{2}
\end{equation*}
$$

 and probably the protonated form of II, i.e. the analog of phosphatrane (I). However, during purification and crystallization, hydrolysis occurred, and compound IV was obtained.

Experimental. - General. All chemicals were purchased from Fluka. The 2,2', $2^{\prime \prime}$-nitrilotriphenol was prepared according to [7]. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra: $\delta$ in ppm rel. to TMS $(=0 \mathrm{ppm}), J$ in Hz . ${ }^{13} \mathrm{P}-\mathrm{NMR}$ spectra: $\delta$ in ppm rel. to $\mathrm{H}_{3} \mathrm{PO}_{4}(=0 \mathrm{ppm}), J$ in Hz .
$2,2^{\prime}, 2^{\prime \prime}$-Nitrilotriphenyl Phosphite (II). Under $\mathrm{N}_{2}, 0.60 \mathrm{~g}(3.9 \mathrm{mmol})$ of tris(dimethylamino)phosphine were added with a syringe to a stirred soin. of $1.00 \mathrm{~g}(3.4 \mathrm{mmol})$ of $2,2^{\prime}, 2^{\prime \prime}$-nitrilotriphenol in 10 ml of $\mathrm{CHCl}_{3}$ contained in a Schlenk tube. The mixture was refluxed for 30 min . After evaporation, the viscous residue was dissolved in 1 ml of MeCN. After standing overnight, colourless crystals separated, which were isolated and dried in vacuo: 380 mg $(35 \%)$ of II. The product is sensitive to air and moisture and has to be kept under an inert atmosphere. IR: 3070w, $3030 w, 1605 w, 1590 w, 1580 w, 1570 \mathrm{v} w(\mathrm{sh}), 1485 \mathrm{vs}, 1450 \mathrm{~m}, 1310 \mathrm{~s}, 1290 \mathrm{w}, 1265 \mathrm{~m}, 1255 \mathrm{~s}, 1235 \mathrm{~s}, 1210 \mathrm{v} \mathrm{w}, 1180 \mathrm{~s}$, $1150 \mathrm{~m}, 1105 m$ (sh), $1095 \mathrm{~m}, 1030 \mathrm{~m}, 970 \mathrm{w}, 950 \mathrm{w}, 935 \mathrm{w}$ (sh), $930 \mathrm{~m}, 910 \mathrm{~s}, 865 \mathrm{~s}, 845 \mathrm{v}, 760 \mathrm{~s}, 745 \mathrm{vs}, 725 \mathrm{~m}, 695 \mathrm{~s}, 620 \mathrm{~m}$, $570 w, 540 w$ (sh), $530 w, 480 m, 415 m, 325 w .{ }^{\prime} \mathrm{H}-\mathrm{NMR}\left(250 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 7.10\left(m, 9 \mathrm{H}, \mathrm{H}-\mathrm{C}\left(4,4^{\prime}, 4^{\prime \prime}\right), \mathrm{H}-\mathrm{C}\left(5,5^{\prime}, 5^{\prime \prime}\right)\right.$, $\mathrm{H}-\mathrm{C}\left(6,6^{\prime}, 6^{\prime \prime}\right)$ ) ; 7.376 (dd, 3H, $\mathrm{H}-\mathrm{C}\left(3,3^{\prime}, 3^{\prime \prime}\right)$ ). ${ }^{31} \mathrm{P}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}\right):+5.20$ (br. s). Anal. calc. for $\mathrm{C}_{18} \mathrm{H}_{12} \mathrm{NO}_{3} \mathrm{P}$ (321.28): C 67.29, H 3.76, N 4.36, P 9.64; found: C 66.90, H 3.88, N 4.60, P 9.27.

Protonation Experiments with II. Addition of strong acids to solns. of II in $\mathrm{CDCl}_{3}$ (NMR tube) resulted in a splitting of the ${ }^{34} \mathrm{P}$-NMR signal and in its shift to more negative $\delta$ values. ${ }^{31} \mathrm{P}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}, 1\right.$ drop of $\left.\mathrm{HBF}_{4}\right)$ : $-14.11(d, J(\mathrm{P}, \mathrm{H})=849)$. An analogous splitted ${ }^{1} \mathrm{H}-\mathrm{NMR}$ signal was observed $\left(\mathbf{H}-\mathbf{P}^{+}\right)$. In a qualitative experiment, 1 drop of a strong acid was added to a soln. of 20 mg of II in 1 ml of $\mathrm{CDCl}_{3}$ and the corresponding ${ }^{1} \mathrm{H}-\mathrm{NMR}$ recorded (see Table I).

Isolation of a crystalline salt of II • $\mathbf{H}^{+}$failed in all cases, i.e. only oils were obtained upon evaporation of the corresponding acidified solutions.
$2,2^{\prime}, 2^{\prime \prime}$-Nitrilotriphenyl Phosphate (III). A soln. of 0.52 g of $\mathrm{POCl}_{3}$ in 10 ml of abs. THF was added under stirring to a soln. of $1.00 \mathrm{~g}(3.4 \mathrm{mmol})$ of $2,2^{\prime}, 2^{\prime \prime}$-nitrilotriphenol and $1.05 \mathrm{~g}(10.2 \mathrm{mmol})$ of $\mathrm{Et}_{3} \mathrm{~N}$ in 10 ml of abs. THF ( $\rightarrow$ white precipitate of $\mathrm{Et}_{3} \mathrm{NHCl}$ ). After completion of the addition, the precipitate was filtered and the filtrate concentrated and chromatographed over a short column of silica gel ( 10 g of silica gel, THF). Evaporation

corrected for crystal decay, Lorentz, and polarization effects; solution by direct methods (MULTAN 77 [8]); weighted least-squares refinements carried out in the XRAY 72 [9] program system, weighting scheme of Seiler and Dunitz [10]. Real and imaginary scattering factors for neutral atoms [11], all non- H -atoms refined anisotropically; H -atoms refined where indicated, others in calculated positions $(d(\mathrm{C}-\mathrm{H})=1.08 \AA)$.

Some difficulties were encountered during the structure determination of II. Density considerations suggested the acentrosymmetric space group $C c$ with 4 molecules in the unit cell. Attempts to solve the structure using MULTAN 77 [8] failed however, and a disordered structure in the centrosymmetric space group $C 2 / c$ was considered ( 8 molecules/unit cell). MULTAN solution yielded a fragment of 4 atoms which could be identified as a tertiary phosphite group. Using the position and orientation of this fragment, a trial structure for the whole cage molecule was calculated and submitted to an isotropic least-squares refinement which converged after a few cycles. Upon anisotropic refinment, $C$-atoms $C(41), C(51), C(61), C(42), C(52), C(62), C(43), C(53)$, and $C(63)$ of the benzene rings had to be constrained to form regular hexagons with $d(\mathrm{C}-\mathrm{C})=1.390 \AA$ and $\alpha(\mathrm{C}-\mathrm{C}-\mathrm{C})=120^{\circ}$ ). H -atoms were introduced in calculated positions with the equivalent isotropic temperature factors of the corresponding C-atoms. All atoms have population parameters of 0.5 . No higher symmetry than $C 2 / c$ could be assigned to the lattice of II. The crystal used was most probably a micro-twin with statistical intermixing of two primitive lattices.

Results and Discussion. - Atomic numbering is seen from the ORTEP drawings. Positional and equivalent isotropic displacement parameters are given in Tables 3 and 4. Anisotropic displacement parameters have been given elsewhere [1]. Molecular structures are illustrated in Fig. 1 and 2. Where possible, bond distances and angles are averaged over the noncrystallographic symmetry elements (3-fold axis). Values for the cage frameworks are reported in Table 5. Additional geometric information is given in [1].

No significant $\mathrm{N} \cdots \mathrm{P}$ interaction is present in II, as illustrated by the $\mathrm{N}-\mathrm{P}$ distance of $3.14 \AA$. The mean $\mathrm{P}-\mathrm{O}$ distance $\left(1.63 \AA\right.$ ) and the $\mathrm{O}-\mathrm{P}-\mathrm{O}$ angles $\left(102.7^{\circ}\right)$ are typical of

Fig. I. ORTEP [15] drawing of molecule II, viewed perpendicular to the 3-fold axis. Atomic numbering is shown for benzene ring 1 ; numbering of rings 2 and 3 is analogous.

Fig. 2. ORTEP [15] drawing of molecule IV, viewed perpendicular to the $N \cdots P$ vector. Atomic numbering is shown for benzene ring 1 ; numbering of rings 2 and 3 is analogous; ring 3 is the dangling one.
a tertiary phosphite ester [14]. The geometry around the N -atom is slightly pyramidalized towards the outside of the cage. The structure of II ressembles thus the structures of the $\mathrm{N}\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{O}\right)_{3} \mathrm{~B}$ fragment in the exocyclic pyridine and quinuclidine adducts of the $2,2^{\prime}, 2^{\prime \prime}$ nitrilotriphenolboron complexes [2].

Table 5. Average Geometries of the Bicycloundecane Framework of II and of the Open Structure IV

|  | II | IV |  |
| :---: | :---: | :---: | :---: |
| $\mathrm{P}-\mathrm{H}(1)$ | - | 1.40(5) |  |
| $\mathrm{P}-\mathrm{N}$ | 3.136(5) | 2.926 (8) |  |
| $\mathrm{P}-\mathrm{O}$ | 1.634(4) | $1.586(6)^{\text {a }}$ ) | $1.453(7)^{\text {c }}$ ) |
| $\mathrm{O}-\mathrm{C}$ | 1.390 (14) | $1.400(10)^{\text {a }}$ ) | $1.362(14)^{\text {b }}$ ) |
| $\mathrm{C}-\mathrm{C}$ | 1.362(18) | $\left.1.381(13)^{2}\right)$ | $1.404(6)^{\text {b }}$ ) |
| $\mathrm{C}-\mathrm{N}$ | 1.427(9) | $1.433(9)^{\text {a }}$ ) | $1.436(7)^{\text {b }}$ ) |
| H-bridge $\mathrm{O}(3)-\mathrm{H}(3) \cdots \mathrm{O}(4)$ |  | $2.721(8)$ |  |
| $\mathrm{P}-\mathrm{O}-\mathrm{C}$ | 126.9(5) | 123.8(4) ${ }^{\text {a }}$ ) |  |
| $\mathrm{O}-\mathrm{C}-\mathrm{C}$ | 122.0(8) | $120.2(4)^{\text {a }}$ ) | $121.6(4)^{\text {b }}$ ) |
| $\mathrm{C}-\mathrm{C}-\mathrm{N}$ | 121.4(10) | 118.7(4) ${ }^{\text {a }}$ ) | $119.2(3)^{\text {b }}$ ) |

| $\mathrm{N}-\mathrm{P}-\mathrm{O}(4)-\mathrm{O}(3)$ |  |  | $7.1{ }^{\text {b }}$ ) |
| $\mathrm{P}-\mathrm{O}(4)-\mathrm{O}(3)-\mathrm{C}(13)$ |  |  | $-47.7^{\text {b }}$ ) |
| $\mathrm{O}(4)-\mathrm{O}(3)-\mathrm{C}(13)-\mathrm{C}(23)$ |  |  | 43.8 ${ }^{\text {b }}$ ) |

[^2]Strong acids protonate the cage of II at the P-atom, as seen from the splitting of the ${ }^{31} \mathrm{P}$-NMR signal into a $d$ and from the appearance of a $d$ in the ${ }^{\mathrm{I}} \mathrm{H}-\mathrm{NMR}$ spectrum with the same coupling constant (see Experimental). The observed ${ }^{31} \mathrm{P},{ }^{1} \mathrm{H}$-coupling constants as well as the 'H-NMR chemical shifts depend to some extent on the nature of the added acid; because of the qualitative nature of these experiments, no definitive conclusions on this dependence seems warranted. AcOH does not protonate II. The II $\cdot \mathrm{H}^{+}$cation is, therefore, much more acidic than the aliphatic phosphatrane (I), which has been reported not to be deprotonated even by as strong bases as methoxide anions [3].

There is evidence for coordination of the nitrilotriphenolat-ligand N -atom to the P-atom upon protonation of the latter to form a tricyclic compound analogous to phosphatrane ( $\mathbf{I}$ ): The low-field shift of the NMR signals of the aromatic protons $o$ to the N -atom ( $\mathrm{H}-\mathrm{C}\left(3,3^{\prime}, 3^{\prime \prime}\right.$ ) by ca. 1 ppm is an indicator for coordination of this N -atom, as shown in the case of the corresponding boron complexes [2]. The rest of the aromatic $m$ ultiplet remains more or less at its original place ( 7.1 ppm ). The protonated adduct could not be isolated in a crystalline form in any of the cases.

The phosphate III has probably a structure very similar to II with no or very little $\mathrm{N} \cdots \mathrm{P}$ interaction, as judged on the chemical shift of the protons $o$ to the N -atom of the nitrilotriphenol ligand. Addition of Lewis- or proton acids results in a pronounced shift of the $\mathrm{H}-\mathrm{C}\left(3,3^{\prime}, 3^{\prime \prime}\right){ }^{\mathbf{I}} \mathrm{H}-\mathrm{NMR}$ signals towards lower field, indicating a coordination of the acid with the $\mathrm{P}=\mathrm{O}$ group with a concomittant coordination of the N -atom to the now positively charged $\mathbf{P}$-atom.

The phosphonate IV is a hydrolysis product of $\mathbf{I I}$; its structure is characterized by a H -bond from the dangling phenol group towards the $\mathrm{P}=\mathrm{O} \mathrm{O}$ O-atom. The geometry around the P -atom is within the range of values normally found for phosphonates [14], and the N -atom of the ligand does not participate in the coordination sphere of the P -atom.

The authors are grateful to Prof. J.D. Dunitz for permission to use his X-ray-diffraction equipment as well as to Dr. P.S. Pregosin for allocation of NMR measurement time and Dr. P. Boron for recording of NMR spectra. E. M. thanks the Swiss National Science Foundation for financial support.
