# 60. Molecular Recognition of NADP(H) and ATP by Macrocyclic Polyamines Bearing Acridine Groups 

by Hicham Fenniri ${ }^{1}$ ), Mir Wais Hosseini ${ }^{1}$ ), and Jean-Marie Lehn *<br>Laboratoire de Chimie Supramoléculaire (CNRS URA 422), Institut Le Bel, Université Louis Pasteur, 4, rue Blaise Pascal, 67000 F-Strasbourg.

(10.II.97)

#### Abstract

The macrocyclic polyamine-based receptor BA bearing two acridine units makes use of combined electrostatic and stacking interactions for the binding of nucleotide polyphosphates and for the recognition of ATP and of NADPH $\left(k_{\mathrm{a}}>3 \cdot 10^{8} \mathrm{~m}\right)$, with a high selectivity for NADPH vs. NADP $\left(c a .10^{3}\right)$ and NAD(H) $\left(>10^{6}\right)$. The binding properties of this receptor towards a variety of substrates led to its in vitro application as a fluorescent probe for ATP. BA also interacts strongly with nucleic acids as shown by spectrophotometric, spectrofluorimetic, and electrophoretic mobility methods.

1. Introduction. - The design of synthetic receptors for the nucleotide ATP and the dinucleotide $\operatorname{NADP}(\mathrm{H})$ represents an important target in molecular recognition chemistry [1-12]. A receptor that can bind with high affinity and selectivity to NADPH vs. NADP, or to ATP vs. other nucleotide phosphates (e.g. CTP, GTP, UTP, ADP, AMP) may allow the design of supramolecular catalysts or sensors [2] of interest for biotechnology and biomedical diagnosis [3]. The cases of ATP and NAD(P)H are particularly interesting, since they represent the ubiquitous energy source to all living organisms. Indeed, receptors and sensors for ATP and NADPH should allow the quantification of this energy in real time, in different tissues as a function of their activity, and depending on their physiological, physicochemical, and pathological states [4].

We describe here the design, synthesis, and physicochemical properties of the macrocyclic receptor BA and its parent monoacridine compound MA [5], as well as their ability to bind a variety of nucleotide phosphates, dinucleotide phosphates, and polynucleotide phosphates.
2. Design of the Receptor Molecules. - Both receptors BA and MA are based on the macrocyclic polyamine [24]- $\mathrm{N}_{6} \mathrm{O}_{2}$ which has been shown to form strong complexes with ATP in aqueous solution [6]. At neutral pH , this polyamine carries 4 protons which are suitably disposed to interact with the 3-4 negative charges of ATP. This electrostatic and geometric complementarity determines in major part the stability of the complexes. The second component of these receptors is an acridine unit, covalently attached to the macrocyclic polyamine through an aminopropyl side arm, and known to undergo fluorescence enhancement upon stacking interaction with aromatic molecules [5] [7].

[^0]

The two acridine units of BA can interact simultaneously with both the adenine and the nicotinamide moieties of $\operatorname{NADP}(\mathrm{H})$, whereas MA, bearing only one acridine group, should interact less effectively with $\operatorname{NADP}(\mathrm{H})$. BA is also expected to interact strongly with ATP, as previously observed for MA and the parent macrocycle [24]- $\mathrm{N}_{6} \mathrm{O}_{2}$ [5]. ATP can form a 'syn' or 'anti' complex with MA (Fig. 1), whereas, with BA, the adenine group may always face an acridine unit. The central unprotonated secondary N -atom in MA has been shown to catalyze the hydrolysis of ATP to ADP [5]. This could become a major limitation if one were to use the receptor to quantify ATP. With BA, this is not the case

$\varepsilon$-ATP

Fig. 1. Schematic representation of the complex BA-ATP and of the relative positioning of the two species. MA having only one 3-(acridin-9-ylamino)propyl moiety can give a 'syn' and an 'anti' form of the complex.
since the amine site responsible for this hydrolytic activity is now tertiary [8]. Finally, the fluorescence enhancement is greater upon complex formation with BA, in part as a result of partial quenching of its intrinsic fluorescence (see below). All these properties make BA a suitable candidate for its use as a fluorescent probe for ATP.

Receptors BA and MA were synthesized according to standard macrocyclic polyamine chemistry [9-12]. The approach adopted allows the generation of symmetrically and nonsymmetrically substituted macrocycles (see Scheme and Exper. Part). A different approach for the preparation of MA has already been reported [5].

Scheme. Preparation of $B A$ and $M A$

$\mathrm{hp}=$ tetrahydro- 2 H -pyran-2-yl, $\mathrm{Ts}=$ toluene-4-sulfonyl

Physicochemical Properties of the Receptors BA and MA. The absorption and emission spectra of MA and BA exhibit similar absorption bands in the VIS and UV region, and an emission band around 450 nm , but their intensity is significantly lower for BA than the sum of two $\mathrm{MA}^{2}$ ).

The effect of concentration, ionic strength, buffer, and temperature on the fluorescence of BA and MA have been examined. The fluorescence of both receptors varies linearly with their concentration below $10^{-5} \mathrm{~m}$, indicating that there is no aggregation in this concentration range. The intrinsic fluorescence of BA is partially quenched indicating that there must be some intramolecular interaction between the two acridine units

[^1]leading to energy transfer. The existence of such a stacking interaction is further supported by NMR data (see Table 1) which indicate a substantially higher-field resonance for the aromatic protons of $\mathrm{BA}(\Delta \delta$ from +0.14 to +0.37 ppm ) as compared to those of MA. Increasing the ionic strength $(\mathrm{NaCl})$ induces a small increase in the fluorescence of BA ( $18 \%$ at 50 mm NaCl ), possibly resulting from decrease of the intramolecular interaction between the two acridine units. Under the same conditions, MA undergoes a fluorescence quenching ( $13 \%$ at 50 mm NaCl ). Other anions lead to the same result (see Sect. 3). The effect of several buffer systems at various concentrations induces similar behavior, the fluorescence being dependent upon the nature of the buffer, its concentration, or both. Except when indicated, 5 mm Tris acetate buffer ( pH 7.6 ) was selected because it led to the highest fluorescence enhancements in the present study.

While the fluorescence intensity of BA is not altered by decreasing the temperature from 37 to $0^{\circ}$, that of MA increases by $68 \%$.
3. Complexation Studies. - 3.1. Complexation of Nucleotide Phosphates: ${ }^{1} \mathrm{H}$ - and ${ }^{1} P$-NMR Studies. Addition of 1 equiv. of ATP to a $10^{-3} \mathrm{~m}$ solution of BA in $\mathrm{D}_{2} \mathrm{O}\left(20^{\circ}\right.$, pD 7 or 4) induces a higher upfield shift of the aromatic ${ }^{1} \mathrm{H}-\mathrm{NMR}$ signals of ATP than observed for MA ( $\Delta \delta$ from +0.58 to $+0.62 \mathrm{ppm} v s .+0.30$ to +0.37 ppm ), probably due to the possible formation of 'syn' and 'anti' complexes with MA (Fig. 1). For the acridine protons, the opposite situation is observed ( $\Delta \delta$ from +0.18 to +0.30 ppm for MA and -0.04 to +0.06 ppm for BA). This behavior is also in agreement with a preexisting interaction between the acridine units of BA, which is inhibited upon complex formation with ATP. Binding of ADP leads to similar effects (see Table 1).

Table 1. ${ }^{1} H-N M R$ Chemical Shifts ( $\delta$ in ppm $)^{\mathrm{a}}$ ) of BA and MA in the Absence and Presence of Equimolar Amounts of Substrate $\left(10^{-3} \mathrm{~m}, 20^{\circ}\right)$ in $\mathrm{D}_{2} \mathrm{O}$

| MA/PPP ${ }^{\text {e }}$ ) | 4 | 8.49 | 8.09 | 7.88 | 7.68 | - | - | - |

[^2]The complexation of triphosphate (PPP) could not be studied at neutral pH because precipitation occurred at the concentration used $\left(10^{-3} \mathrm{~m}\right)$. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ upfield shifts of the acridine moiety upon complexation of PPP to MA at a pH where precipitation did not occur ( pH 4 ) are insignificant ( $\Delta \delta$ from 0 to +0.05 ppm ) but appreciable with BA $(\Delta \delta$ from +0.09 to $+0.16 \mathrm{ppm})$.

Under the same experimental conditions, the ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectra show an upfield shift in the resonance of $\mathrm{P}(\alpha), \mathrm{P}(\beta)$, and $\mathrm{P}(\gamma)$ of ATP upon complexation to MA [5] ( $\Delta \delta-0.07$ +1.32 , and +2.20 ppm , resp.) and $\mathrm{BA}(\Delta \delta+0.05,+1.27$, and +2.92 ppm resp. $)$

The NMR studies indicate that BA may exist in a 'folded' structure, in which the acridines interact in an intramolecular fashion, and that, upon addition of ATP, a complex is formed where the adenine moiety of ATP interacts with the acridine units of the receptors through stacking interactions, and the triphosphate moiety with the polyammonium macrocycle through electrostatic interactions.
3.2. Complexation of Nucleotide Phosphates: UV/VIS Absorption Properties and Fluorescence Studies. The UV/VIS spectra of both receptors remain unchanged upon addition of 1 equiv. of ATP. In the presence of a large excess of ATP ( 20 equiv.), the bands at 221 and 265 nm show an important hypochromic effect ( $30 \%$ ) and a weak bathochromic shift ( 2 nm ) with respect to a solution of ATP in the buffer ([receptor $]=10^{-5} \mathrm{~m}$ in 5 mm Tris acetate buffer, $\mathrm{pH} 7.6,20^{\circ}$ ).

At high ionic strength $(\mathrm{NaCl})$, competitive binding of chloride may alter the binding ability of both receptors. Indeed, it has been shown that protonated polyamines complex $\mathrm{Cl}^{-}$[12]. Thus, in the presence of 50 mm NaCl , the fluorescence of the ATP complexes of BA and MA are quenched by 50 and $26 \%$, respectively $\left(5 \cdot 10^{-1} \mathrm{~m}, 5 \mathrm{~mm}\right.$ Tris acetate, $\mathrm{pH} 7.6,20^{\circ}$ ). Similar results were obtained from the study of different buffers and their concentration effect on the fluorescence of the ATP complexes (data not shown).

Upon addition of 1 equiv. of ATP, the fluorescence increases by $150 \%$ for MA, and by $250 \%$ for BA without any shift in the emission wavelength. Titration curves show the formation of a stable 1:1 complex with ATP (Fig. 2). The histogram (Fig. 3) summarizes the fluorescence enhancement upon addition of 1 equiv. of various nucleotide phosphates to both receptors. BA undergoes the highest fluorescence enhancement upon ATP binding. Neither adenosine nor PPP nor a combination of the two induces such a high fluorescence enhancement, indicating that the binding of ATP is governed essentially by electrostatic interaction between the polyammonium moiety of the receptor and the triphosphate chain of ATP and that fluorescence enhancement results from stacking interactions between the acridine and the adenine parts. Titration of CTP, UTP, and GTC with both receptors also indicate the formation of stable 1:1 complexes (data not shown) but their effects on the fluorescence varies considerably with the nature of the base and the receptor. Thus, both CTP and UTP induce a fluorescence enhancement, whereas GTP quenches the fluorescence of MA, and slightly increases that of BA. The higher fluorescence enhancement obtained with ATP as compared to the other nucleotide triphosphates could be the result of a better stacking interaction with purines [13] as compared to pyrimidines. The fluorescence quenching of acridines in the presence of GTP has already been reported [7c] [13] [14]. The fact that BA is not quenched by GTP is in agreement with the effect of NaCl , and PPP, and could again originate from the hindrance of the preexisting interactions in BA that compensates for the quenching induced by GTP.

Fig. 2. Fluorimetric titration curve of $B A\left(2.5 \cdot 10^{-6} \mathrm{~m}\right.$ in 2.5 mm Tris acetate buffer, $\left.\mathrm{pH} 7.6,20^{\circ}\right)$ by ATP ( $\lambda_{\text {exc }} 412 \mathrm{~nm}, \hat{\lambda}_{\mathrm{em}} 450 \mathrm{~nm}$ )

Fig. 3. Histogram showing the percentage of fluorescence enhancement of $B A$ and $M A\left(5 \cdot 10^{-6} \mathrm{~m}\right.$ in 5 mm Tris acetate buffer, $\mathrm{pH} 7.6,20^{\circ}$ ) in the presence of 1 equiv. of various substrates. $\mathrm{PPP}=$ Triphosphate.

In order to further characterize the interaction with these receptors, we also carried out a study of a fluorescent analogue of ATP, $\varepsilon$-ATP [15] (Fig. 1). The excitation wavelength ( 300 nm ) of this substrate is distant from those of the receptors, but it emits very close to them $(410 \mathrm{~nm})$. Fluorescence titration experiments demonstrate the formation of 1:1 complexes with BA and MA (see also [5]). In the presence of 1 equiv. of $\varepsilon$-ATP, the fluorescence of BA is increased by $96 \%$ and quenched by $36 \%$ in the case of MA. This behavior resembles the one observed with GTP, i.e., a fluorescence quenching with MA, and a fluorescence enhancement with BA. As discussed above, the inhibition of an intramolecular interaction in BA which induces a fluorescence quenching in the free receptor, could compensate for the fluorescence quenching induced by this substrate on one of the acridines. When the substrate was excited ( 300 nm ), the titration curves in the presence of MA and BA were superimposable, indicating that the substrate interacts similarly with both receptors. In both cases the fluorescence of $\varepsilon$-ATP is quenched ( $78 \%$ ). The emission spectra upon excitation at 300 nm show a tailing down to 550 nm (maximum at 410 nm ) which may be due to an energy transfer from $\varepsilon$-ATP to the acridine.
3.3. Complexation of Dinucleotide Phosphates: ${ }^{1} H-N M R$ and ${ }^{31} P-N M R$ Studies. NMR studies were carried out at neutral pD when the complex was soluble; alternatively pD 4 was used for less soluble complexes. The NADPH complexe with BA (see Fig. 4) could not be studied by NMR ( 200 MHz ) since at the concentration used $\left(10^{-3} \mathrm{~m}\right)$ the complex was insoluble, even at pD 4 ; below pD 4, NADPH is highly unstable [16]. It was, however, possible to study this complex at pH 7.6 by spectrofluorimetry because of the low concentration required for this technique (see Sect. 3.4).

As summarized in Table 2, the complexation induces small upfield shifts on the adenosine protons of $\mathrm{NAD}(\Delta \delta$ from +0.22 to +0.26 ppm with BA and +0.13 to +0.17 ppm with MA) and has essentially no effect on the nicotinamide moiety, indicating that this part of the substrate does not interact with the acridine groups of the receptors. This could result from the repulsive interaction between the positive charge carried by this group and the protonated acridine. As a result of the presence of two acridine units in BA, the chemical shifts are substantially higher. The upfield shifts of the acridine proton signals of both receptors upon complex formation are quite small ( $\Delta \delta$ from -0.01 to +0.03 ppm for BA and +0.03 to +0.06 ppm for MA), in agreement with a weak interaction between the receptors and NAD.

NADH which is lacking the positive charge of the nicotinamide interacts with the receptors via both its adenosine and nicotinamide moieties. The upfield ${ }^{1} \mathrm{H}-\mathrm{NMR}$ chemical shifts ( $\Delta \delta$ ) induced by BA vary from +0.32 to +0.47 ppm for the adenosine portion and +0.22 to +0.31 ppm for the nicotinamide group. With MA, $\Delta \delta$ ranges from +0.19 to +0.37 ppm for the adenosine part and from +0.14 to +0.26 ppm for the nicotinamide moiety. Here again, the chemical shifts induced by BA are more pronounced.

NADP which differs from NAD by the phosphoryl group on the $2^{\prime}$-hydroxy group of the adenosine (Fig. 4) displays much larger effects with both receptors (pD 7). The upfield shifts ( $\Delta \delta$ ) induced by BA vary from +0.25 to +1.44 ppm for the adenosine moiety and from +0.22 to +0.65 ppm for the nicotinamide, while with MA, they range from +0.14 to +0.49 ppm for the adenosine moiety and from +0.03 to +0.10 ppm for the nicotinamide. Although the nicotinamide is positively charged, its ${ }^{1} \mathrm{H}-\mathrm{NMR}$

$$

$$

$$
\text { NAD } R=H, \quad \text { NADP } \quad R=\mathrm{PO}_{3}{ }^{2 \ominus}
$$

Fig. 4. Structure of $N A D(P) H$ and $N A D(P)$, and schematic representation of the complex $B A-N A D P H$
signals display an important upfield shift with BA, whereas with MA, the upfield shift is small, indicating that the single acridine of MA prefers to interact with the adenine rather than with the positively charged nicotinamide.
$\Delta \delta$ Values induced by MA on NADPH at pD 7 are more pronounced than with NADP $(+0.32$ to +0.56 ppm for the adenosine moiety and +0.05 to +0.19 ppm for the nicotinamide part) for the same reason that makes NADH interact more strongly than NAD with this receptor, namely the repulsive interaction between the positive charge on the nicotinamide of NAD and the protonated acridines.
${ }^{31} \mathrm{P}-\mathrm{NMR}$ of the same complex under the same conditions indicate no change in the chemical shifts for the pyrophosphate moiety of NAD and NADH. For NADP an upfield chemical shift is observed with MA ( +0.33 ppm for the terminal $\mathrm{P}(\alpha)$ and -0.05 ppm for $\mathrm{P}(\beta)$ and $\mathrm{BA}(+0.32 \mathrm{ppm}$ for $\mathrm{P}(\alpha)$ and -0.24 ppm for $\mathrm{P}(\beta))$. NADPH could not be studied for solubility reasons (see above).

[^3]3.4. Complexation of Dinucleotide Phosphates: Fluorescence Studies. Spectrofluorimetric studies could be carried out either by exciting the receptor ( 408 and 412 nm for MA and BA, resp.), the substrate ( $\lambda_{\text {exc }} 340 \mathrm{~nm}$ in the case of $\mathrm{NAD}(\mathrm{P}) \mathrm{H}, \lambda_{\text {em }} c a .455 \mathrm{~nm}$ ), or both. Titration of the receptors with NAD and NADH do not show any significant change in the fluorescence spectra of the receptors or of the substrate (in the case of NADH), a result apparently at variance with ${ }^{1} \mathrm{H}$-NMR studies. But since the concentrations used in the present experiments are 100 to 500 times lower, the interaction detected by ${ }^{1} \mathrm{H}$-NMR may not be detectable spectrofluorimetrically. Furthermore, spectrofluorimetric studies were carried out in the presence of ca. 1000-fold excess of acetate anions (from the buffer) over substrate which weakens the interaction.

On the other hand, $\operatorname{NADP}(\mathrm{H})$ which differs from $\operatorname{NAD}(\mathrm{H})$ only by the phosphorylation of the adenosine ribose at the $2^{\prime}$-position forms stable complexes with both receptors, indicating the critical role played by this group in the recognition of this substrate. Fig. 5 shows the spectrofluorimetric titration of NADH and NADPH by BA. The complex formation was followed by exciting the reduced nicotinamide moiety of NAD(P)H at 340 nm and monitoring the emission at 455 nm . NADPH formed a stable 1:1 complex with BA, whereas NADH did not appear to interact with this receptor. Similar results were obtained with MA, although the fluorescence extinction was less pronounced with NADPH.

Upon excitation of the receptor and not of the substrate, the results were consistent with the previous one, that is $\operatorname{NAD}(\mathrm{H})$ had no effect on the fluorescence of either of the two receptors (Fig. 6), and NADPH induced a weak fluorescence enhancement of both BA and MA with titration curves clearly indicating the formation of stable 1:1 complexes (data not shown). NADP was bound more weakly to both receptors and saturation was obtained after the addition of 10 equiv. of substrate. The fluorescence enhancement was much higher than with any other substrate investigated; it reached $850 \%$ for BA and

Fig. 5. Fluorimetric titration curves of NADH and NADPH ( $5 \cdot 10^{-6} \mathrm{~m}$ in 5 mm Tris acetate buffer $\mathrm{pH} 7.6,20^{\circ}$ ) by $B A\left(\lambda_{\text {exc }} 340 \mathrm{~nm}, \lambda_{\text {em }} 455 \mathrm{~nm}\right)$

Fig. 6. Histogram showing the fluorescence enhancement of BA and MA (5•10 ${ }^{-6} \mathrm{~m}$ in 5 mm Tris acetate buffer $\mathrm{pH} 7.6,20^{\circ} ; \lambda_{\text {exc }} 408 \mathrm{~nm}$ for MA and 412 nm for $\left.\mathrm{BA}, \lambda_{\text {em }} 450 \mathrm{~nm}\right)$ in the presence of 1 equiv. of $N A D(P) H$ and $N A D(P)$
$250 \%$ for MA in the presence of 10 equiv. of NADP. The weaker interaction of NADP in comparison with NADPH could result from its lower overall charge (3 negative charges instead of 4 for NADPH), and from unfavorable repulsive interactions between the positively charged nicotinamide and the protonated acridines of the receptors (see NMR studies).

Table 3. Stability Constants $\mathrm{K}_{s}$ for Receptor/Substrate Pairs

| Receptor/Substrate | $K_{\text {s }}\left[\mathrm{M}^{-1}\right]$ | Method |
| :---: | :---: | :---: |
| BA/ATP | $7 \cdot 10^{7}$ | titration ${ }^{\text {a }}$ ) |

| MA/NADPH | $\geq 10^{7}$ | " |

${ }^{\text {a }}$ ) In all cases, [receptor] $=5 \cdot 10^{-6} \mathrm{~m}$ in 5 mm Tris acetate buffer, pH 7.6 , except for ATP titrations where [receptor] $=2.5 \cdot 10^{-6}$ in 2.5 mm Tris acetate buffer, $20^{\circ} \mathrm{pH} 7.6$.
${ }^{\text {b }}$ ) The fluorescence decrease was monitored upon addition of [24]- $\mathrm{N}_{6} \mathrm{O}_{2}$ (competitor) to an equimolar solution of ATP and BA.
${ }^{c}$ ) The fluorescence decrease was monitored upon addition of PPP (competitor) to an equimolar solution of ATP and BA or MA.
${ }^{4}$ ) The fluorescence decrease was monitored upon addition of NADPH (competitor) to an equimolar solution of ATP and BA or MA (see supplementary material).
3.5. Stability of the Complexes. The stability of some of the complex studied was evaluated either directly by spectrofluorimetric titration or indirectly via competition experiments. The results obtained are summarized in Table 3. It is seen that very strong complexes are formed.

A comparison of the stability constants of [24]- $\mathrm{N}_{6} \mathrm{O}_{2}$-ATP and BA-ATP indicates that the acridine groups increase the stability by more than an order of magnitude. A similar effect was observed in a study of adenine complexation by receptors bearing anthracene units [17]. BA binds PPP as strongly as ATP, because PPP possesses an extra negative charge that compensates for the stacking interaction observed with ATP.

PPP, ATP, and NADPH form the strongest complexes with MA and BA. The selectivity of binding of NADPH over NADP by BA amounts to a factor of 600 . This selectivity as well as the stability achieved with NADPH compare well with those obtained with NAD enzymes ${ }^{3}$ ).

Finally, notwithstanding the structural dissimilarities between ATP and NADPH, BA binds both substrates with almost the same strength suggesting a structural adaptation of the receptor to these substrates as a result of its flexibility, and also showing that the stability of the complexes is determined mainly by electrostatic interactions.
4. Interaction with Double-Stranded DNA. - 4.1. General. Apart from its ability to strongly bind ATP and NADPH, BA also presents analogies with the natural bis-intercalator triostin A [19] [20]. The macrocyclic moiety of BA and MA forms stable ternary complexes with two $\mathrm{Cu}^{\text {II }}$ atoms and one molecule of phosphate ( $K_{\mathrm{s}}=3 \cdot 10^{4} \mathrm{~m}^{-1}$ ) [21]. It has also been shown that simple oligo(ethylenediamines) catalyze RNA hydrolysis under physiological conditions [22]. BA possesses a binding site for two metals, as well as two acridine moieties which upon intercalation into double-stranded nucleic acids could bring the metal ions in close proximity to the phosphate backbone and thus catalyze its hydrolysis [23].
4.2. UV/VIS Spectroscopy. Three isosbestic points ( 229,236 , and 282 nm ) were obtained upon titration of calf thymus DNA (CT-DNA) with BA indicating the existence of two major species in solution and thus that the complex with DNA is very stable. A strong hypochromic effect was recorded at $359 \mathrm{~nm}(73 \%)$ in the presence of 0.3 equiv. of BA to CT-DNA.

The same experiment was performed by titrating the receptor ( $10^{-5} \mathrm{~m}$ ) with CT-DNA and monitoring the changes around 400 nm . The maximum bathochromic shift ( 4 nm ) was obtained after adding 2.8 equiv. of CT-DNA. An important hypochromic effect was also recorded ( $39 \%$ ).
4.3. Spectrofluorimetry. The interaction of BA was also studied spectrofluorimetrically with CT-DNA, poly-d(G-C), and poly-d(A-T) as shown in Fig. 7. The results with acridin-9-amine (9-AA) were added for comparison as this compound is known to interact with double-stranded DNA by intercalation [20e] [24]; they indicate a strong interaction of acridin-9-amine with double-stranded DNA, in agreement with [20 e] [24]. The titration curves of acridin-9-amine with poly-d(G-C) and CT-DNA are superimposable, whereas with poly-d(A-T), the fluorescence quenching is not complete although the

[^4] [18].

Fig. 7. Fluorimetric titration curves of BA and acridin-9-amine (9-AA) by calf thymus DNA (CT-DNA), poly-d (A-T), and poly-d(G-C)
binding seems to be as strong. This is also in agreement with a preferred interaction of acridin-9-amine with G-C sequences [20e] [24].

In the presence of double-stranded DNA, the emission band of BA underwent a hypsochromic shift ( 5 nm ) [25]. With poly-d(A-T), the fluorescence increases linearly with the concentration of DNA, whereas with poly-d(G-C), the opposite situation is observed (Fig. 7). The fluorescence is almost completely quenched upon addition of 4 equiv. of poly-d(G-C), in agreement with the formation of a very stable complex, and with a complete site occupation if one takes into account the adjacent base exclusion principle [26] and the overall acridine concentration in solution. With CT-DNA, the behavior is intermediate between poly- $\mathrm{d}(\mathrm{G}-\mathrm{C})$ and poly- $\mathrm{d}(\mathrm{A}-\mathrm{T})$; the fluorescence is first quenched and then slowly restored upon addition of CT-DNA. At higher concentrations of CT-DNA ( $>10$ equiv., data not shown), the fluorescence increases linearly with CT-DNA concentration. The reasons for this behavior are not clear although the results show that BA forms stable complexes, at least with poly-d(G-C).
4.4. Electrophoretic Mobility. The electrophoretic mobility [27] of supercoiled plasmid pBr 322 on agarose gel in the presence of micromolar concentration of BA was strongly retarded. Acridin-9-amine, [24]- $\mathrm{N}_{6} \mathrm{O}_{2}$, or an equimolar mixture of the two at micromolar concentration had no effect on the migration ability of supercoiled plasmid pBr 332 although it is known that polyamines [28] and acridine [25] derivatives interact strongly with double-stranded DNA.
5. Conclusion. - The results described here show how electrostatic and stacking interactions can be combined in an artificial receptor BA for the recognition of complex biological molecules. The quenching of the acridine fluorescence indicates that BA exist in a 'folded' form which opens up on substrate binding leading to a fluorescence enhancement. BA binds a variety of nucleotide polyphosphates and in particular, it strongly
complexes ATP. Furthermore, NADPH which differs from NADP only by the nicotinamide moiety is bound $\geq 600$ times more tightly. Whilst $\mathrm{NAD}(\mathrm{H})$ interacts weakly with BA, the stability of the complex BA-NADPH ( $K_{\mathrm{s}} \geq 3 \cdot 10^{8}$ ) and the selectivity obtained for NADPH vs. NADP is comparable to, and even higher in some cases than that measured for NAD enzymes [18].

It is clear that the combination of different types of intermolecules interactions in suitably designed receptor molecules allows strong and selective binding, i.e., molecular recognition of a variety of substrates of chemical and biological interest.

## Experimental Part

1. General. M.p.: Digital Thomas-Hoover apparatus (Electrotherma). Chromatography: silica gel Merck 60 ( $0.063 \sim 0.200 \mathrm{~mm}$ ), silica gel 'flash' Merck $60(0.040-0.063 \mathrm{~mm})$, or alumina Merck act. II-III ( $0.063-0.200 \mathrm{~mm}$ ); $\mathrm{FC}=$ flash chromatography. NMR Spectra: Bruker $A C 200\left(200.1 \mathrm{MHz}\right.$ for ${ }^{1} \mathrm{H}$ and 50.3 MHz for $\left.{ }^{13} \mathrm{C}\right) ; \delta$ in ppm and $I$ in Hz , with the solvent as internal reference; spectra in $\mathrm{D}_{2} \mathrm{O}$ with 2-methyl-propan-2-ol as internal reference (Me, 1.36 ppm ; $\mathrm{HOC}\left(\mathrm{CH}_{3}\right)_{3}, 68.7$ and 31.6 ppm , resp. The fast atom bomdardment ( FAB ) mass spectra were performed by the Service de Spectrométrie de Masse de l'Université Louis Pasteur de Strasbourg and elemental analyses by the Service de Microanalyse de l'Université Louis Pasteur de Strasbourg.
2. Synthesis of the Receptors. Acridin- $9(10 \mathrm{H})$-one, acrylonitrile, toluene-4-sulfonyl chloride, methanesulfonyl chloride, and 3,4-dihydro-2H-pyran were purchased from Aldrich. The synthesis of 2 [29], $\mathbf{3}$ [30], 10-12, MA [5], and 9 -chloroacridine [31] has already been reported. MA was obtained via 10 which was prepared in this study by a different synthetic route.
$\mathrm{N}, \mathrm{N}^{\prime}$-\{/(2-Cyanoethyl) iminoldi(ethane-2,1-diyl)\}bis[4-methylbenzenesulfonamide] (1). Acrylonitrile ( 24 ml , 365 mmol ) was added to a soln. of $N, N^{\prime}$-[iminodi(ethane-2,1-diyl)]bis[4-methylbenzenesulfonamide] [32] ( 15 g , 36.5 mmol ) in benzene ( 230 ml ). The mixture was refluxed under $\mathrm{N}_{2}$ for 5 days. After cooling to r.t., evaporation yielded a colorless oil which was dried under vacuum for 24 h . Compound 1, was obtained as white crystals from $\mathrm{CHCl}_{3} /$ hexane ( $15.3 \mathrm{~g}, 90 \%$ ). $R_{\mathrm{f}} 0.4\left(\mathrm{SiO}_{2}, 3 \% \mathrm{MeOH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$ ). M.p. $106-107^{\circ} .{ }^{1} \mathrm{H}-\mathrm{NMR}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right.$, $\left.25^{\circ}, \mathrm{SiMe}_{4}\right): 2.33\left(t,{ }^{3} J=6.6, \mathrm{CH}_{2} \mathrm{CN}\right) ; 2.41\left(s, 2 \mathrm{MeC}_{6} \mathrm{H}_{4}\right) ; 2.54\left(t,{ }^{3} J=4.8,2 \mathrm{TsNHCH}_{2} \mathrm{CH}_{2} \mathrm{~N}\right) ; 2.61\left(t,{ }^{3} J=9\right.$, $\left.\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CN}\right) ; 2.88\left(t,{ }^{3} \mathrm{~J}=4.8 \mathrm{~Hz}, 2 \mathrm{CH}_{2} \mathrm{NHTs}\right) ; 5.76(t, 2 \mathrm{NHTs}) ; 7.3\left(d,{ }^{3} \mathrm{~J}=8.1,4\right.$ arom. 4,10,16,22-Tetrakis/(4-methylphenyl) sulfonyl]-1,13-dioxa-4,7,10,16,19,22-hexaazacyclotetracosane-7,19-dipropanamine (8). A soln. of $7(1.5 \mathrm{~g}, 1.4 \mathrm{mmol})$ in anh. THF (distilled over $\mathrm{Na} ; 30 \mathrm{ml}$ ) was stirred under $\mathrm{N}_{2}$ for 15 min . To this soln., $1 \mathrm{~m} \mathrm{~B}_{2} \mathrm{H}_{6}$ in THF ( 70 ml ) was added and the mixture stirred under reflux for 22 h . The soln. was cooled to $0^{\circ}$ and the excess $\mathrm{B}_{2} \mathrm{H}_{6}$ carefully destroyed by adding slowly a soln. of $\mathrm{H}_{2} \mathrm{O} / \mathrm{THF} 1: 1$. The resulting mixture was evaporated and the white solid obtained refluxed in $6 \mathrm{M} \mathrm{HCl}(150 \mathrm{ml})$ for 7 h . The white solid obtained after evaporation was dried under high vacuum ( 24 h ), dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(200 \mathrm{ml}$ ), and washed with 2 M NaOH ( 200 ml ). The aq. layer was further extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \times 150 \mathrm{ml})$. The org. layers were dried $\left(\mathrm{MgSO}_{4}\right)$ and evaporated and the residue dried under high vacuum ( 24 h ). 8 as a yellow oil ( $1.3 \mathrm{~g}, 86 \%$ ) which was used in the next step without further purification. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}, 25^{\circ}, \mathrm{SiMe}_{4}\right): 1.79\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right)$; 2.1-2.4 ( $\mathrm{m}, 12 \mathrm{H}, \mathrm{CH}_{2} \mathrm{~N}$ ) ; $2.41\left(\mathrm{~s}, 12 \mathrm{H}, \mathrm{MeC}_{6} \mathrm{H}_{4}\right) ; 3.04\left(t,{ }^{3} \mathrm{~J}=4,4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{NH}_{2}\right) ; 3.35\left(t,{ }^{3} \mathrm{~J}=5,16 \mathrm{H}, \mathrm{CH}_{2} \mathrm{NTs}\right)$; $3.58\left(t,{ }^{3} J=4.5,8 \mathrm{H}, \mathrm{CH}_{2} \mathrm{O}\right) ; 7.3\left(d,{ }^{3} J=9,8\right.$ arom. H); $7.68\left(d,{ }^{3} J=9,8\right.$ arom. H$)$.

N,N-Di(acridin-9-yl)-4,10,16,22-tetrakis[(4-methylphenyl) sulfonyl]-1,13-dioxa-4,7,10,16,19,22-hexaazacy-clotetracosane-7,19-dipropaneamine (9). A mixture of 8 ( $1.3 \mathrm{~g}, 1.2 \mathrm{mmol}$ ), phenol ( $5.65 \mathrm{~g}, 60 \mathrm{mmol}$ ), and 9 -chloroacridine [31] ( $0.52 \mathrm{~g}, 2.4 \mathrm{mmol}$ ) was heated at $80^{\circ}$ under Ar for 8 h . After cooling, the residue was taken up in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(100 \mathrm{ml})$ and washed with 2 m aq . $\mathrm{NaOH}(40 \mathrm{ml})$. The aq. layer was further extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $2 \times 25 \mathrm{ml}$ ), the combined org. phase dried $\left(\mathrm{MgSO}_{4}\right)$ and evaporated, and the residue submitted to chromatography (alumina, $0-2 \% \mathrm{MeOH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) followed by crystallization from hot $\mathrm{EtOH}: 9(0.43 \mathrm{~g}, 25 \%) . R_{\mathrm{f}} 0.33$ $\left(\mathrm{Al}_{2} \mathrm{O}_{3}, 5 \% \mathrm{MeOH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$ ). M.p. $95-96^{\circ} .{ }^{1} \mathrm{H}-\mathrm{NMR}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}, 25^{\circ}, \mathrm{SiMe}_{4}\right): 1.96(m, 4 \mathrm{H}$, $\left.\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right) ; \quad 2.4\left(s, \quad 12 \mathrm{H}, \quad M e \mathrm{C}_{6} \mathrm{H}_{4}\right) ; \quad 2.76\left(t, \quad{ }^{3} J=5, \quad 4 \mathrm{H}, \quad \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{~N}\right) ; \quad 2.92\left(t \quad{ }^{3} J=7.8, \quad 8 \mathrm{H}\right.$, $\left.\mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NTs}\right) ; 3.23\left(m, 16 \mathrm{H}, \mathrm{CH}_{2} \mathrm{NTs}\right) ; 3.5\left(t,{ }^{3} \mathrm{~J}=4.3,8 \mathrm{H}, \mathrm{CH}_{2} \mathrm{O}\right) ; 4.03\left(t,{ }^{3} \mathrm{~J}=6,4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{NHAcr}\right) ; 7.12$ $\left(d,{ }^{3} J=8,8\right.$ arom. C of Ts); 135.71, 143.29 (arom. $\mathrm{CSO}_{2}$, arom. CMe). FAB-MS (pos.): $1431.2\left([M+1]^{+}\right)$. Anal. calc. for $\mathrm{C}_{76} \mathrm{H}_{90} \mathrm{~N}_{10} \mathrm{O}_{10} \mathrm{~S}_{4}+1 \mathrm{H}_{2} \mathrm{O}(1449.88)$ : C $62.96, \mathrm{H} 6.39, \mathrm{~N} 9.66$; found: C 62.70 , H 6.27, N 9.85.
$\mathrm{N}, \mathrm{N}$ '-Di(acridin-9-yl)-1,13-dioxa-4,7,10,16,19,22-hexaazacyclotetracosane-7,19-dipropaneamine (BA). A mixture of $9(0.26 \mathrm{~g}, 0.18 \mathrm{mmol})$, phenol $(0.4 \mathrm{~g}, 4.3 \mathrm{mmol})$, and $33 \% \mathrm{HBr}$ in $\mathrm{AcOH}(31 \mathrm{ml})$ was stirred at $80^{\circ}$ for 38 h . After cooling, $\mathrm{Et}_{2} \mathrm{O}(60 \mathrm{ml})$ was added, and the precipitate obtained was filtered, washed with $\mathrm{Et}_{2} \mathrm{O}(100 \mathrm{ml})$, and dried under high vacuum. The yellow solid was dissolved in distilled $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{ml})$ and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(2 \times 20 \mathrm{ml})$. The aq. layer was basified to pH ca. 14 with 4 m NaOH and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \times 20 \mathrm{ml})$. Evaporation of the org, layer yielded a yellow oil which was taken up in abs. EtOH ( 10 ml ) and acidified with conc. HCl soln. to pH ca. 1. The precipitate formed was isolated by centrifugation, resuspended in $\mathrm{EtOH}(10 \mathrm{ml})$, and recentrifuged. This operation was repeated a third time. The yellow solid was dried under vacuum to yield BA. $8 \mathrm{HCl}(0.2 \mathrm{~g}, 66 \%)$. M.p. $267^{\circ}$ (dec.) NMR: the $\delta \mathrm{s}$ depend strongly upon the concentration and the pH of the medium. ${ }^{1} \mathrm{H}$-NMR ( $200 \mathrm{MHz}, 10^{-3} \mathrm{M}$ in $\mathrm{D}_{2} \mathrm{O}$ at $\mathrm{pD} 7,25^{\circ}, \mathrm{SiMe}_{4}$ ): $2.31\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right) ; 2.94\left(t,{ }^{3} \mathrm{~J}=7\right.$ $4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH} 2 \mathrm{~N}$ ); $3.06\left(t,{ }^{3} J=8,8 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NCH}_{2}\right) ; 3.31\left(t, 8 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{~N}\right) ; 3.4$ $\left(t, 8 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{O}\right) ; 4.0\left(t, 8 \mathrm{H}, \mathrm{CH}_{2} \mathrm{O}\right) ; 4.15\left(t,{ }^{3} J=7,4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{NHAcr}\right) ; 7.61\left(\mathrm{~m}, 8 \mathrm{H}, \mathrm{H}_{\mathrm{C}}, \mathrm{H}_{\mathrm{D}}\right) ; 7.98\left(t,{ }^{3} J=8\right.$, $\left.4 \mathrm{H}, \quad \mathrm{H}_{\mathrm{B}}\right) ; 8.28\left(d,{ }^{3} J=9,4 \mathrm{H}, \mathrm{H}_{\mathrm{A}}\right) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(50 \mathrm{MHz}, 10^{-3} \mathrm{M}\right.$ in $\mathrm{D}_{2} \mathrm{O}$ at $\left.\mathrm{pD} 7,25^{\mathrm{D}}, \mathrm{SiMe}_{4}\right)$ : $26.45\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right) ; 46.92\left(\mathrm{CH}_{2}\right.$ NHAcr $) ; 49.06,49.49,51.25\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{~N}\right) ; 51.56\left(\mathrm{NCH}_{2}-\right.$ $\mathrm{CH}_{2} \mathrm{O}$ ); $67.29\left(\mathrm{CH}_{2} \mathrm{O}\right) ; 120.25,136.0,137.26,159.16$, (acridine). FAB-MS (pos.): 815.3 ( $\mathrm{M}^{+}$of unprotonated BA (calc. 815.13)), $[M+1]^{+}$and $[M+2]^{2+}$ are hardly detectable (ca. $5 \%$ ). Anal. calc. for $\mathrm{C}_{48} \mathrm{H}_{74} \mathrm{~N}_{10} \mathrm{O}_{2}+8 \mathrm{HCl}+$ $4 \mathrm{H}_{2} \mathrm{O}$ (1178.88): C 48.91, H 7.01, N 11.88 ; found: C 49.03, H 7.01, N 11.45.

BA is stable in the solid octahydrochloride form. It can be stored at low temp. ( $+4^{\circ}$ ) for a few months in aq. acidic solns. Under neutral or slightly basic conditions, the product starts decomposing in less than 4 weeks, most likely via the displacement of the acridine unit to yield the corresponding acridin-9 $(10 \mathrm{H})$-one.

Preparation of MA. The preparation of this compound has been reported earlier [5]. We describe here a different approach where the key step is the macrocyclization step, leading directly to the functionalized polyamine 10. The following steps leading to 11, 12 and MA (not described here) are similar to those previously reported [5].

4,10,16,19,22-Pentakis [(4-methylphenyl) sulfonyl]-1,13-dioxa-4,7,10,16,19,22-hexaazacyclotetracosane-7-propanenitril (10). A soln. of $6(9.36 \mathrm{~g}, 11.74 \mathrm{mmol})$ in anh. DMF (distilled over $\mathrm{NaH} ; 500 \mathrm{ml})$ was added dropwise under $\mathrm{N}_{2}$ pressure within 3 h to a mechanically stirred mixture of $N, N^{\prime}$ - $\{\{[(4$-methylphenyl)sulfonyl]-imino\}di(ethan-2,1-diyl)\} bis[4-methylbenzenesulfonamide] (3) [30] ( $6.64 \mathrm{~g}, 11.74 \mathrm{mmol}$ ) and $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ ( 30.6 g , 94 mmol ) in anh. DMF (distilled over $\mathrm{NaH}, 1000 \mathrm{ml}$ ), at $100^{\circ}$. After the addition, the temp. was maintained at $100^{\circ}$ for an additional 51 h . DMF was evaporated and the residual solid resuspended in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 400 ml ), filtered over Celite, and washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The org. layers were washed with dist. $\mathrm{H}_{2} \mathrm{O}$, dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, and evaporated. The brownish oil thus obtained was filtered over silica gel $\left(1 \% \mathrm{MeOH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ and purified by FC ( $\mathrm{SiO}_{2}, 0-0.5 \% \mathrm{MeOH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ ): $\mathbf{1 0}(7 \mathrm{~g}, 50 \%)$. Yellowish oil. $R_{\mathrm{f}} 0.5\left(\mathrm{SiO}_{2}, 2 \% \mathrm{MeOH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}\right) .{ }^{1} \mathrm{H}-\mathrm{NMR}$ $\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}, 25^{\circ}, \mathrm{SiMe}_{4}\right): 2.4\left(m, 17 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CN}, M e \mathrm{C}_{6} \mathrm{H}_{4}\right) ; 2.65-2.9\left(m, 6 \mathrm{H}, \mathrm{CH}_{2} \mathrm{~N}\right) ; 3.1-3.45(m, 20 \mathrm{H}$, $\mathrm{CH}_{2} \mathrm{NTs}$ ); $3.56\left(\mathrm{~m}, 8 \mathrm{H}, \mathrm{CH}_{2} \mathrm{O}\right) ; 7.25-7.4(\mathrm{~m}, 10$ arom. H$) ; 7.6-7.75(\mathrm{~m}, 10$, arom. H$) .{ }^{13} \mathrm{C}-\mathrm{NMR}(50 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}, 25^{\circ}, \mathrm{SiMe}_{4}\right): 16.93\left(\mathrm{CH}_{2} \mathrm{CN}\right) ; 21.55\left(\mathrm{MeC}_{6} \mathrm{H}_{4}\right) ; 48.06,48.21,49.04,49.43,49.74\left(\mathrm{CH}_{2} \mathrm{NTs}\right)$; $50.05\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CN}\right) ; 53.63\left(\mathrm{TsNCH}_{2} \mathrm{CH}_{2} \mathrm{~N}\right) ; 69.63,69.95\left(\mathrm{CH}_{2} \mathrm{O}\right) ; 119.1(\mathrm{CN}) ; 127.32,127.46,129.87,129.93$, $135.45,136.21,136.51,143.46,143.65,143.89$ (arom.).
3. Physicochemical Measurements. Spectrophotometric and Spectrofluorimetric Data of the Receptors and Their Complexes. UV/VIS Spectra: Cary-III instrument. Fluorescence spectra: Shimadzu RF-540 equipped with a photomultiplicator Hamamatsu HTV RG28 and a recorder Shimadzu DR-3. The excitation wavelength was produced by a Xe lamp. Except when indicated, the fluorescence measurements were performed in a $1 \times 1 \mathrm{~cm}$ quartz cell at a concentration of $5 \cdot 10^{-6} \mathrm{M}$ for the receptors, in 5 mm Tris acetate buffer, pH 7.6 , at $20^{\circ}$. The acquisition parameters were the following: $\lambda_{\text {exc }} 412 \mathrm{~nm}$ for BA , and 408 nm for MA, excitation slit 10 nm , emission slit 10 nm , sensitivity high.

For BA in 100 mm Tris acetate buffer, pH 7.6 , at $20^{\circ}: \varepsilon_{221} \quad 40900 \mathrm{~mol}^{-1} \mathrm{I}^{-1} \mathrm{~cm}^{-1}$, $\varepsilon_{265} 78900 \mathrm{~mol}^{-1} \mathrm{l}^{-1} \mathrm{~cm}^{-1}, \varepsilon_{394} 13200 \mathrm{~mol}^{-1} \mathrm{l}^{-1} \mathrm{~cm}^{-1}, \varepsilon_{412} 18900 \mathrm{~mol}^{-1} \mathrm{l}^{-1} \mathrm{~cm}^{-1}, \varepsilon_{434} 15700 \mathrm{~mol}^{-1} 1^{-1} \mathrm{~cm}^{-1}$. For MA in 100 mM Tris acetate buffer, pH 7.6 , at $20^{\circ}: \varepsilon_{221}=31900 \mathrm{~mol}^{-1} \mathrm{l}^{-1} \mathrm{~cm}^{-1}, \varepsilon_{265} 68000 \mathrm{~mol}^{-1} \mathrm{l}^{-1} \mathrm{~cm}^{-1}$, $\varepsilon_{394} 6200 \mathrm{~mol}^{-1} \mathrm{l}^{-1} \mathrm{~cm}^{-1}, \varepsilon_{412} 11500 \mathrm{~mol}^{-1} \mathrm{l}^{-1} \mathrm{~cm}^{-1}, \varepsilon_{434} 9800 \mathrm{~mol}^{-1} \mathrm{l}^{-1} \mathrm{~cm}^{-1}$. Upon excitation at 412 nm in 5 mm Tris acetate buffer, pH 7.6 , at $20^{\circ}$, BA and MA ( $5 \cdot 10^{-6} \mathrm{~m}$ ) exhibited an emission maximum at 450 nm .

NMR Data. ${ }^{1} \mathrm{H}$ - and ${ }^{31} \mathrm{P}$-NMR Spectra: Bruker $A C 200\left(200.1 \mathrm{MHz}\right.$ for ${ }^{1} \mathrm{H}$ and 81.028 MHz for $\left.{ }^{31} \mathrm{P}\right)$, 2-methylpropan-2-ol as internal reference for ${ }^{1} \mathrm{H}\left(\mathrm{CH}_{3}, 1.36 \mathrm{ppm}\right)$ and conc. $\mathrm{H}_{3} \mathrm{PO}_{4}$ soln. as external reference
$(S R=-10795.12)$ for ${ }^{31} \mathrm{P}$. The spectra were recorded under the following conditions; [receptor] = [substrate] $=10^{-3} \mathrm{~m}$, at $20^{\circ}$ in $\mathrm{D}_{2} \mathrm{O}$. The pD was adjusted by addition of few $\mu \mathrm{l}$ of conc. HCl or NaOH soln.

Interactions with DNA. Titration of BA by CT-DNA. CT-DNA (Sigma) was first extracted with phenol/ $\mathrm{CHCl}_{3}$ ( 3 times) and precipitated by EtOH before use. Poly- $\mathrm{d}(\mathrm{G}-\mathrm{C}$ ) and poly-d(A-T) were used as obtained from Sigma. BA was added in increments of 0.06 equiv. to an UV cell containing a soln. of CT-DNA $\left(87.6 \cdot 10^{-6} \mathrm{~m}\right.$, in 50 mm Tris acetate buffer, $\mathrm{pH} 7.6,20^{\circ}$ ) and to another one containing the buffer only (reference). The spectra were recorded as the difference between the cell containing the CT-DNA and the reference. After the seventh increment ( 0.42 equiv. negligible volume), DNA started precipitating as a yellow complex with BA.

Titration of CT-DNA by BA. CT-DNA was added in increments of 0.1 equiv. (negligible volume) to a UV cell containing BA ( $10^{-5} \mathrm{~m}$, in 50 mm Tris acetate buffer $\mathrm{pH} 7.6,20^{\circ}$ ) and to another one containing the buffer only (reference). The spectra recorded as the difference between the cell containing BA and the reference.

[^0]:    ${ }^{1}$ ) Present addresses: H.F, The Scripps Research Institute, Beckman Center for Chemical Sciences, La Jolla, CA 92037, USA; M.W.H., Laboratoire de Chimie de Coordination Organique, Institut Le Bel, Université Louis Pasteur, 4, rue Blaise Pascal, F-67000 Strasbourg.

[^1]:    ${ }^{2}$ ) Part of the physical properties of MA have already been described under different experimental conditions, see [5].

[^2]:    ${ }^{\text {a }}$ ) With respect to ${ }^{t} \mathrm{BuOH}$ as internal reference ( $\mathrm{Me}, 1.36 \mathrm{ppm}$ ).
    ${ }^{\text {b }}$ ) pH adjusted with conc. NaOH and HCl solutions.
    ${ }^{\text {c }}$ ) Acridine protons as shown in Fig. 1, $\mathrm{H}_{\mathrm{A}}$ and $\mathrm{H}_{\mathrm{C}}$ are $d \mathrm{~s}, \mathrm{H}_{\mathrm{B}}$ and $\mathrm{H}_{\mathrm{D}}$ are ts.
    ${ }^{\text {d }}$ ) Nucleotide protons are as shown in Fig. 1.
    ${ }^{\text {e }}$ ) $\mathrm{PPP}=$ triphosphate.

[^3]:    ${ }^{\text {a }}$ ) With respect to ${ }^{\prime} \mathrm{BuOH}$ as internal reference ( $\mathrm{Me}, 1.36 \mathrm{ppm}$ ).
    ${ }^{\text {b }} \mathrm{pH}$ adjusted with conc. NaOH and HCl solutions.
    ${ }^{\text {c }}$ ) Acridine protons as shown in Fig. 4, $\mathrm{H}_{\mathrm{A}}$ and $\mathrm{H}_{\mathrm{C}}$ are ds, $\mathrm{H}_{\mathrm{B}}$ and $\mathrm{H}_{\mathrm{D}}$ are ts.
    ${ }^{\text {d }}$ ) Nucleotide protons are as shown in Fig. 4 .

[^4]:    ${ }^{3}$ ) E.g., lactate dehydrogenase has a selectivity of 15 in favor of NADH, and a $K_{\mathrm{m}}$ of $10^{-5} \mathrm{~m}$ for this cofactor
