Palladium-catalyzed intramolecular reactions of 2-bromo 1,6-dienes followed by intermolecular [4+2] cycloaddition with suitable dienophiles in one-pot operations gave hexahydroindenes **8** and **9** in yields of 40–78%, an hexahydro-*s*-indacene derivative **13** could be obtained in up to 25% yield with cyclopent-2-en-1-one (**10**) as a dienophile in the presence of different *Lewis* acids, and a spirocyclopentane-hexahydroindenone **18** could be isolated in 72% yield. When *in-situ*-formed iminium salts were used as heterodienophiles, hexahydro-1*H*-[2]pyrindinols **31** could be obtained in a one-pot two-step operation in 29–46% yield.

Introduction. – Domino reactions have emerged as a particularly versatile method for the construction of bi- and tricyclic systems, as they achieve the stereocontrolled formation of more than two new bonds in a single operational step [1]. Among the many new transition-metal-catalyzed reactions, the Pd-catalyzed *Heck* cross-coupling reaction has become one of the most important methods for C–C bond-formation [2]. Hexahydroindenes are easily prepared in a one-pot procedure starting from 2-bromo 1,6-dienes, which, by an intramolecular *Heck* reaction, first afford a 1,2-dimethylidenylcyclopentane[1]) that, in the presence of a dienophile, immediately undergoes an intermolecular *Diels*–*Alder* reaction. The reaction has been thoroughly studied for 2-bromo 1,6-dienes containing a dialkyl malonate unit at the 4-position, simply because the starting materials can easily be prepared by twofold alkylation of dialkyl malonates [4]. Geminal disubstitution in the open-chain precursor does play a role in the intramolecular *Heck* reaction because of the *Thorpe-Ingold* effect [5], but it is not essential for the success of the intramolecular coupling [4a]. With regard to the synthesis of natural products, the geminal ester groups would have to be replaced by geminal dimethyl groups. Therefore, in this paper, we report a study of the synthesis and Pd-catalyzed cyclization of 2-bromo 1,6-dienes with geminal dimethyl groups with respect to various Pd catalysts, solvents, bases, and ligands.

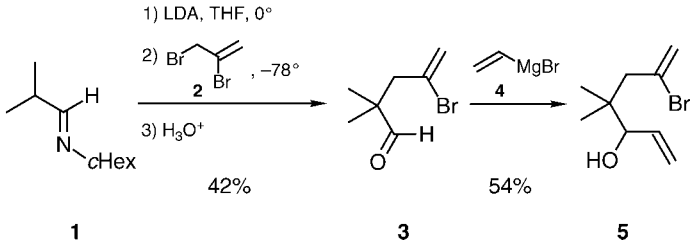
[1]) Dimethylidenylcycloalkanes can also be formed by cyclization of acetylenic vinyllithiums generated from the corresponding acetylenic vinyl bromides by Li/Br exchange [3].

Results and Discussion. – *Formation of Carbocyclic Systems.* The synthesis of 2-bromo 1,6-dienes with geminal dimethyl groups is not as straightforward as that with geminal diester groups, which are disubstituted dialkyl malonates [4a]. However, the imine **1**, prepared from isobutyraldehyde and cyclohexylamine, can be deprotonated with lithium diisopropylamide (LDA) [6], and alkylation of the azaenolate with 2,3-dibromopropene (**2**) followed by acid-catalyzed hydrolysis furnishes the bromo aldehyde **3** in 42% isolated yield. Because of its instability, **3** has to be immediately converted further, *e.g.*, by reaction with vinylmagnesium bromide (**4**) to give 2-bromo-4,4-dimethylhepta-1,6-dien-5-ol (**5**) in 54% yield (*Scheme 1*).

Scheme 1. *Preparation of 2-Bromo-4,4-dimethylhepta-1,6-dien-5-ol* (**5**)



2-Bromo 1,6-dienes of type **5** have been shown to cyclize in the presence of $Pd(OAc)_2$, Ph_3P, and K_2CO_3 or Ag_2CO_3 to afford 1,2-bis(exomethylene)cyclopentanes of type **6**, which can subsequently undergo *Diels–Alder* reactions to give hexahydroindene derivatives **8** and **9**. As previous studies have revealed that the yields without isolation of intermediate **6** are consistently higher than those obtained in two steps, the reactions of **5** with acrylates and methyl vinyl ketone were carried out as single one-pot operations (*Scheme 2*) [4][7].

In a typical experiment, a solution of the bromo diene **5** (1 mmol), the dienophile **7** (3 mmol), a base (1.2–2 mmol), $Pd(OAc)_2$ (5 mol%), and Ph_3P (10 mol%) was heated in anhydrous MeCN at 80° for 18 h.

In an effort to elucidate the conditions for this transformation, the 2-bromo 1,6-diene **5** in the presence of various dienophiles and different bases was subjected to such conditions. The products, mixtures of regioisomers and diastereoisomers **8** and **9**, were obtained in higher yields when K_2CO_3 instead of Ag_2CO_3 was used as a base. The latter is known to suppress not only double-bond migration but also the *Heck* reaction (*Table 1*, *Entries 1*, *3*, and *5*). The best yields resulted with methyl acrylate (*Entries 1* and *2*), but the regioisomeric excess was low, even when the sterically more-demanding *tert*-butyl acrylate was used (*Entries 3* and *4*). Each regioisomer was a mixture of diastereoisomers. The diastereoisomeric ratios could not be determined from the ^{1}H-NMR spectra of the mixtures since the peaks were not well-resolved.

[a]) The ratios of the regioisomers were determined by integration of the relevant peaks in the ^{1}H-NMR spectra after oxidation of **8** and **9** to the corresponding ketones.

With cyclopent-2-en-1-one (**10**) as a dienophile, this *Heck–Diels–Alder* reaction should allow easy access to decahydro-*s*-indacene derivatives [8]. Because of the low reactivity of **10** under the established conditions described above, only decomposition could be detected after 14 days of heating. Carrying out the reaction as a one-pot two-step operation, in which the *Diels–Alder* reaction was performed at 10 kbar [9], gave the regioisomeric decahydro-*s*-indacene derivatives **11** and **12** after 4 d in 31% yield as a mixture of diastereoisomers (*Scheme 3*).

Diels–Alder reactions can be accelerated not only by high pressure (for recent reviews on high-pressure chemistry, see [9]), but also by addition of *Lewis* acids such as $LiBF_4$ [10], $BF_3 \cdot OEt_2$, dialkylaluminum chlorides, trialkylaluminum, or alkoxytitanium halides. With $LiBF_4$ added to the mixture of **5**, **10**, and the catalyst cocktail, the hexahydro-*s*-indacene derivative **13** was obtained as the only product, which must be formed from **11** by *Lewis* acid promoted elimination of H_2O. The reaction time of 14 d was very long, and even the best yield was only 25% (*Table 2*, *Entry 1*). Apparently, the dimethylidenylcyclopentanol **6** is not stable enough under these conditions for extended times. Therefore, Et_2AlCl was tested as a *Lewis* acid. After only 18 h, the product **13** could be isolated in 22% yield, but a large number of unidentified side products were also formed (*Entry 2*). In our search for a *Lewis* acid that is not as strong as Et_2AlCl but strong enough to catalyze the reaction, $AlMe_3$ and $Ti(O^iPr)_4$ were also tested (*Entries 4* and *5*). With these, however, no hexahydro-*s*-indacene derivative was observed; only the starting material could be recovered. With only 1.5 equiv. of

[a]) Additionally, 17% of diene **6** was recovered. [b]) Only decomposition was observed.

Et_2AlCl, only 6% of **13** and 17% of the dimethylidenylcycloalkane could be isolated (*Entry 3*).

After this partial success with an added *Lewis* acid, the *Diels–Alder* reaction of the preformed intermediate **6** with methyl acrylate (**7a**) was also tested in the presence of Et_2AlCl.

Towards that end, a solution of Et_2AlCl (3 equiv.) and **7a** (3 equiv.) in MeCN, which had been stirred for 15 min, was added to the mixture containing **6**, and stirring was continued at ambient temperature for 1 d. The expected tetrahydroindene **14** could be isolated in 26% yield, along with a considerable amount of decomposition product.

To avoid the formation of diastereoisomeric mixtures, the bromoheptadienol **5** was oxidized to the ketone **15** according to the *Swern* protocol [11]. Surprisingly, when the bromodienone **15** was treated with the Pd catalyst in the presence of **7a**, the expected product **17** was not observed, but the hexahydrospiro(cyclopentaneinden)one **18** was isolated as a single product in 72% yield (*Scheme 5*). Even in the presence of a large excess of **7a** (10 equiv.), only **18** was formed. Apparently, the α,β-unsaturated enone moiety in the 5,5-dimethyl-2,3-dimethylenecyclopentanone **16** first formed is a far better dienophile than **7a**. It is remarkable that the hexahydroindenone **18** was formed as a single regio- as well as diastereoisomer, the structure of which was established by X-ray-analysis (*Fig.*)[2]).

The mono- and dimethyl-substituted bromodienes **25** and **27** could be prepared from the *t*-Bu-substituted isobutyraldehyde imine in close analogy to the synthesis of **5** with (*E*)-1,2-dibromobut-2-ene (**22**) and 1,2-dibromo-3-methylbut-2-ene (**23**) instead of 2,3-dibromopropene in the alkylation of the azoenolate. In view of the illudine sesquiterpenes with their tetrahydroindene skeleton, the synthesis of such compounds

with a Me group at C(4) of the hexahydroindene derivative was of interest in this context [12].

Deprotonation of **21** with LDA, alkylation with **22** or **23**, and acidic workup gave the aldehydes **24** and **26** in moderate yields of 54 and 48%, respectively. Addition of vinylmagnesium bromide (**4**) yielded the bromodienes **25** and **27** in 45 and 47% yields, respectively (*Scheme 6*).

When the bromodiene **25** was subjected to the usual conditions of the domino *Heck–Diels–Alder* reaction, the exocyclic diene **20** could be isolated in 45% yield, but only a trace of the hexahydroindenes **19** could be detected. It is a bit surprising that the *Diels–Alder* reaction of **20** did not occur easily in spite of the s-*cis* conformation of its 1,3-diene unit.

Under the same conditions, the dimethyl-substituted bromodiene **27** gave no bicyclic compound at all. Only the isopropenylcyclopentenol **28** was isolated in 74% yield; **28** probably results from the exocyclic diene **29** first formed by isomerization, which can occur either by re-addition with reversed regioselectivity of the eliminated hydridopalladium bromide and subsequent elimination of hydridopalladium bromide [13], or by a concerted suprafacial 1,5-H-shift. Cyclopentadienes are known to undergo such 1,5-H-shifts rapidly at room temperature; for this rearrangement to occur in acyclic or exocyclic dienes, higher temperatures ($>250°$) are usually required [14], although the s-*cis* conformation of **29** should facilitate such a 1,5-H-shift. The substitution pattern in the resulting diene **28** does not favor a conformation that would allow a *Diels–Alder* reaction to occur.

Formation of Heterocyclic Systems. Since N-containing heterocyclic systems are of particular interest because of their potential biological activities, the domino *Heck–Diels–Alder* sequence was also applied to the preparation of azabicycles. This can be achieved by incorporation of the N-atom in the cyclization precursor, as described in an earlier publication [15].

Another possibility is to use N-atom-containing dienophiles, such as imines and nitroso compounds [16]. For such hetero-*Diels–Alder* reactions, either the imines have to be electron deficient or the dienes particularly electron rich. Activation by added *Lewis* acids has also been used in many cases. *Larsen* and *Grieco* reported that imines formed *in situ* from formaldehyde and an amine hydrochloride react with unactivated dienes without added *Lewis* acids [17]. This approach has been adopted for the use with formaldehyde and amino acid ester hydrochlorides by *Waldmann* [18].

Since formaldehyde would immediately reduce the $Pd(OAc)_2$ precatalyst to inactive Pd black, the domino *Heck–Diels–Alder* reaction of the 2-bromo 1,6-diene

5 with such iminium hydrochlorides had to be carried out by the one-pot two-step variant [15]. Thus, a mixture of **5**, $Pd(OAc)_2$ (5 mol%), Ph_3P (10 mol%), and K_2CO_3 (1 equiv.) in MeCN was first heated at 80° for 18 h. After cooling to room temperature, formaldehyde, glycine methyl ester hydrochloride (**30a**), and H_2O were added. After an additional 18 h at ambient temperature, the hexahydro-1*H*-[2]pyrindene derivative **31a** could be isolated in 26% yield as a single regioisomer (*Table 3*, *Entry 1*). This yield could be improved to 38% by reducing the amount of K_2CO_3 from 1 equiv. to 0.5 equiv. (*Entry 2*) [15]. In an effort to evaluate the scope and limitations of this transformation, **5** was subjected to various conditions (*Entries 3–6*). With Ag_2CO_3 as the base, the yield was only 11% (*Entry 3*). Neither using MeOH instead of water nor heating to 50° increased the yield (*Entries 4* and *5*). In a reaction with the *in-situ*-formed iminium salt from cyclopentylamine (**30d**), the change from MeCN to THF for the first step led to incomplete reaction; 45% of the exocyclic diene **6** could be recovered (*Entry 11*). In an attempt to carry out the *Diels–Alder* reaction under a pressure of 10 kbar, only

decomposition was observed (*Entry 6*). The best yields were obtained when only 0.5 equiv. of K_2CO_3 was used. Under these optimized conditions, different amines were tested. The use of NH_4Cl led only to decomposition (*Entry 8*). Benzylamine hydrochloride (**30b**) gave **31b** in 46% yield (*Entry 7*); cyclopropylamine hydrochloride (**30c**) led to **31c** in only 36% yield (*Entry 9*). Cyclopentylamine hydrochloride (**30d**) and cyclohexylamine hydrochloride (**30e**) also gave low yields of 31 and 29% of **31d** and **31e**, respectively (*Entries 10* and *12*). In all cases, the iminium salts formed *in situ* gave only a single isolated regioisomer, in contrast to the reactions with most all-C dienophiles (see above).

Conclusions. – A one-step synthesis of bicyclic and tricyclic compounds starting from 2-bromohepta-1,6-dienes with geminal dimethyl groups has been accomplished. Although, with all-C dienophiles, the regioselectivities are not very high, this approach is noteworthy in view of its simplicity. With *in-situ*-generated iminium hydrochlorides, azabicycles are formed in low-to-moderate yields, but with complete regioselectivity.

Method B. When K_2CO_3 (276 mg, 2.00 mmol) was used as the base, 145 mg (70%) of a mixture of **8c** and **9c** was isolated.

*1,2,3,3a,5,6,8,8a-Octahydro-6,6-dimethyl-*s*-indacene-1-one* (**13**). *Method A*. According to *GP 1*, **5** (219 mg, 1.00 mmol) in anh. MeCN (10 ml) was treated with $Pd(OAc)_2$ (11 mg, 0.050 mmol, 5 mol-%), Ph_3P (26 mg, 0.10 mmol, 10 mol-%), and K_2CO_3 (138 mg, 1.00 mmol) at 80° for 18 h. After cooling to ambient temp., *cyclopentenone* (**10**) (410 mg, 4.99 mmol) and $LiBF_4$ (94 mg, 1.0 mmol) were added. After the mixture had been stirred at ambient temp. for 14 d, the solvent and dienophile were removed under reduced pressure. CC (18 g SiO_2; 2.0 × 15 cm; pentane/Et_2O, 4:1) gave 51 mg (25%) of **13** as a colorless oil. R_f (pentane/Et_2O, 4:1) 0.46. IR (film): 3058, 2961, 1737 (C=O), 1650, 1434, 1406, 1267, 1172, 1034, 919, 737, 703. ^{1}H-NMR (250 MHz, $CDCl_3$): 0.99 (*s*, Me–C(6)); 1.04 (*s*, Me–C(6)); 1.84–1.91 (*m*, H–C(3)); 2.01–2.40 (*m*, 7 H, H–C(2), H–C(3), H–C(5), H–C(8), H–C(8a)); 2.83 (*d*, ^3J = 12.8 Hz, H–C(8)); 3.07 (br. *s*, H–C(3a)); 5.19 (br. *s*, H–C(4));

Method B. Et_2AlCl (3.0 ml, 3.0 mmol, 1.0M in hexane) was added instead of $LiBF_4$, and the resulting mixture was stirred at ambient temp. for 18 h. The Et_2AlCl was hydrolyzed with H_2O (15 ml) and the aq. layer was extracted with Et_2O (3 × 20 ml). The org. phases were dried ($MgSO_4$), and the solvent was removed under reduced pressure. CC (18 g SiO_2; 2.0 × 15 cm; pentane/Et_2O 4:1) gave 45 mg (22%) of **13** as a colorless oil. R_f (pentane/Et_2O, 4:1) 0.46.

Method C. The use of a soln. of Me_3Al (1.50 ml, 3.00 mmol, 2M in toluene) instead of Et_2AlCl did not give any cycloaddition product within 72 h.

Method D. When $Ti(O^iPr)_4$ (853 mg, 3.00 mmol) was used as a *Lewis* acid, only decomposition was observed within 72 h.

Method E. When the reaction was carried out with a smaller amount of Et_2AlCl (1.5 ml, 1.5 mmol, 1.0M in hexane) within 12 h, only 13 mg (6%) of **13** and 24 mg (17%) of **6** (for spectroscopic data, see **31d**) could be isolated.

*Methyl 2,4,5,6-Tetrahydro-2,2-dimethyl-1*H*-indene-5-carboxylate* (**14**). According to *GP 1*, **5** (219 mg, 1.00 mmol) in anh. MeCN (10 ml) was treated with $Pd(OAc)_2$ (11 mg, 0.050 mmol, 5 mol-%), Ph_3P (26 mg, 0.10 mmol, 10 mol-%), and K_2CO_3 (138 mg, 1.00 mmol) at 80° for 18 h. After cooling to r.t., **7a** (258 mg, 3.00 mmol) and Et_2AlCl (3.0 ml, 3.0 mmol, 1.0M in hexane) were added, and stirring was continued for 1 d at ambient temp. H_2O was added (5 ml), the aq. layer was extracted with Et_2O (2 × 10 ml), and the combined org. phases were dried ($MgSO_4$). After evaporation of the solvent *in vacuo*, the resulting crude product was purified by CC (18 g SiO_2; 2.0 × 15 cm; pentane/Et_2O, 4:1) to give 53 mg (26%) of **14** as a colorless oil[3]. *(*E*)-6-Bromo-4,4-dimethylocta-1,6-dien-3-ol* (**25**). To a soln. of 50.0 mmol of LDA in anh. THF (25 ml), **21** (4.71 g, 37.0 mmol) and *(*E*)-1,2-dibromobut-2-ene* (**22**) (7.91 g, 37.0 mmol) were added and stirred for 2 h at −78°. The resulting mixture was quenched with AcOH/H_2O/NaOAc (1:4:1), and the aq. layer was extracted with Et_2O (3 × 50 ml) and dried ($MgSO_4$). The solvent was removed under reduced pressure to yield 4.12 g (54%) of *4-bromo-2,2-dimethylhex-4-enal* (**24**), which was immediately dissolved in anh. THF (25 ml), and vinylmagnesium bromide (30 ml, 30 mmol, 1.0M in THF) was added at −78°. After warming to r.t., H_2O (50 ml) was added, the aq. layer was extracted with Et_2O (3 × 30 ml), the combined org. layers were dried (Na_2SO_4), and the solvent was removed under reduced pressure. CC of the crude product (80 g SiO_2; 3.5 × 20 cm; CH_2Cl_2) yielded 2.13 g (45%) of **25** as a colorless oil. R_f (CH_2Cl_2) 0.48. General Procedure for the Heck–*Hetero*-Diels–Alder *Reaction as a Two-Step One-Pot Operation* (*GP 2*). In a screw-cap *Pyrex* bottle was placed the bromo diene (1 mmol) dissolved in anh. MeCN (10 ml). To the resulting soln. were added $Pd(OAc)_2$ (5 mol-%), Ph_3P (10 mol-%), and K_2CO_3 (50 mol-%). N_2 was bubbled through the mixture for 5 min, then the bottle was closed and heated to 80° for the given time. After cooling to r.t., formaldehyde (1 ml, 37% in H_2O), amine hydrochloride (2 mmol), and H_2O (8 ml) was added and stirring was continued for the given time at ambient temp. The mixture was filtered through *Celite* and washed with H_2O. The combined filtrates were extracted with Et_2O (20 ml), and NaOH (2M) was added to the aq. layer until pH 13. The aq. layer was extracted with Et_2O (3 × 20 ml). The combined org. layers were washed with sat. NaCl soln. (20 ml), dried (Na_2SO_4), and the solvent was removed under reduced pressure. The crude product was purified by CC.

*Methyl (2,3,4,5,6,7-Hexahydro-7-hydroxy-6,6-dimethyl-1*H*-[2]pyrinden-2-yl)acetate* (**31a**). *Method A*. As described in *GP 2*, a soln. of **5** (219 mg, 1.00 mmol) in anh. MeCN (10 ml) was treated with $Pd(OAc)_2$ (11 mg, 0.050 mmol, 5.0 mol-%), Ph_3P (26 mg, 0.10 mmol, 10 mol-%), and K_2CO_3 (69 mg, 0.50 mmol) and stirred for 18 h at 80°. After cooling to r.t., a soln. of HCHO (1.0 ml, 12 mmol, 37% in H_2O), methyl glycinate hydrochloride (**30a**, 251 mg, 2.00 mmol), and H_2O (8 ml) were added, and stirring was continued for 18 h at r.t. After workup, the crude product was purified by CC (18 g SiO_2; 2.0 × 15 cm; CH_2Cl_2/MeOH 20:1 → 10:1) to yield 92 mg (38%) of **31a** as a colorless oil. R_f (CH_2Cl_2/MeOH 10:1) 0.21. Method B. The use of K_2CO_3 (138 mg, 1.00 mmol) decreased the yield of **31a** to 63 mg (26%).

Method C. When Ag_2CO_3 (138 mg, 0.500 mmol) was added instead of K_2CO_3, only 27 mg (11%) of **31a** could be isolated.

Method D. The addition of MeOH (8 ml) instead of H_2O lowered the yield of **31a** to only 10 mg (4%).

Method E. When the hetero-*Diels–Alder* reaction was carried out at 10 kbar, only a decomposition product and oligomeric material was obtained.

Method F. When the *Diels–Alder* reaction was performed at 50°, an unidentified side product was formed, and the yield of **31a** decreased to 9 mg (4%).

Stirring was continued for 18 h at r.t. The crude product was purified by CC (18 g SiO_2; 2.0 × 15 cm; CH_2Cl_2/MeOH 10:1) to give 72 mg (31%) of **31d** as a colorless oil. R_f (CH_2Cl_2/MeOH 10:1) 0.13. IR (film): 3437 (OH), 3053, 2956, 2864, 2806, 1696, 1464, 1381, 1361, 1265, 1053, 894, 868, 736, 703. ^{1}H-NMR (250 MHz, $CDCl_3$): 1.02 (*s*, Me–C(6)); 1.06 (*s*, Me–C(6)); 1.48–1.76 (*m*, 6 cyclopentyl H, OH); 1.88–2.07 (*m*, 1 cyclopentyl H, H–C(4), H–C(5)); 2.15–2.27 (*m*, 1 cyclopentyl H, H–C(4), H–C(5)); 2.58–2.82 (*m*, 1 cyclopentyl H, 2 H–C(1)); 2.97–3.13 (*m*, H–C(3)); 3.22–3.38 (*m*, H–C(3)); 4.00 (br. *s*, H–C(7)). ^{13}C-NMR (62.9 MHz, $CDCl_3$): 23.0 (*Me*–C(6)); 24.0 (cyclopentyl CH_2); 26.1 (C(4)*); 28.9 (*Me*–C(6)); 30.2 (cyclopentyl CH_2); 41.5 (C(6)); 48.5 (C(5)*); 49.1 (C(1)**); 50.2 (C(3)**); 67.1 (cyclopentyl CH); 85.5 (C(7)); 133.0 (C(4a)***); 137.0 (C(7a)***). EI-MS: 235 (62, M^+), 218 (15, $[M-OH]^+$), 206 (70), 192 (28, $[M-C_2H_5N]^+$), 179 (45, $[M-C_3H_6N]^+$), 163 (100, $[M-C_4H_{10}N]^+$), 150 (6), 123 (7), 98 (10), 84 (8), 68 (14), 41 (22, $C_3H_5^+$).

Method B: When the reaction was carried out in anh. THF (10 ml) instead of MeCN, in addition to 23 mg (10%) of **31d**, 62 mg (45%) of *2,2-dimethyl-4,5-dimethylidenecyclopentan-1-ol* (**6**) could be isolated as a colorless oil[4]). R_f (pentane/Et_2O 4:1) 0.45. ^{1}H-NMR (250 MHz, $CDCl_3$): 0.82 (*s*, Me–C(2)); 1.07 (*s*, Me–C(2)); 1.49 (*d*, ^3J = 7.9 Hz, OH); 2.22 (m_c, 2 H–C(3)); 4.06 (*ddd*, ^3J = 7.9, ^4J = 2.3, ^4J = 2.3 Hz, H–C(1)); 4.90 (m_c, 1 H, C=CH_2); 5.10 (*d*, ^2J = 2.2 Hz, 1 H, C=CH_2); 5.43 (m_c, 1 H, C=CH_2); 5.48 (*d*, ^2J = 2.2 Hz, 1 H, C=CH_2). ^{13}C-NMR (62.9 MHz, $CDCl_3$): 19.6 (*Me*–C(2)); 25.7 (*Me*–C(2)); 39.8 (C(2)); 44.3 (C(3)); 82.6 (C(1)); 105.4 (C=*C*H_2); 105.9 (C=*C*H_2); 144.0 (C(5)*); 151.0 (C(4)*). EI-MS (70 eV): 138 (33, M^+), 123 (100, $[M-Me]^+$), 109 (12), 105 (20, $[M-Me-H_2O]^+$), 95 (73), 91 (11), 79 (16), 67 (30), 55 (16), 43 (16), 41 (13, $C_3H_5^+$).

*2-Cyclohexyl-2,3,4,5,6,7-hexahydro-6,6-dimethyl-1*H*-[2]pyrinden-7-ol* (**31e**). According to *GP 2*, to a soln. of **5** (219 mg, 1.00 mmol) in anh. MeCN (10 ml) was added $Pd(OAc)_2$ (11 mg, 0.050 mmol, 5.0 mol-%), Ph_3P (26 mg, 0.10 mmol, 10 mol-%), and K_2CO_3 (69 mg, 0.50 mmol). The resulting mixture was stirred for 18 h at 80°. After cooling to r.t., a soln. of HCHO (1.0 ml, 12 mmol, 37% in H_2O), cyclohexylamine hydrochloride (**30e**, 271 mg, 2 mmol), and H_2O (8 ml) was added and stirring was continued for 18 h at r.t. CC (18 g SiO_2; 2.0 × 15 cm; CH_2Cl_2/MeOH 10:1) yielded 73 mg (29%) of **31e** as a colorless oil. R_f (CH_2Cl_2/MeOH, 10:1) 0.23. IR (film): 3352 (OH), 2930, 2856, 1668, 1451, 1380, 1264, 1205, 1135, 1069, 1036, 1003, 894, 737, 702. ^{1}H-NMR (250 MHz, $CDCl_3$): 1.03 (*s*, Me–C(6)); 1.06 (*s*, Me–C(6)); 1.14–1.36 (*m*, 6 cyclohexyl H); 1.62–2.21 (*m*, 4 cyclohexyl H, 2 H–C(4), 2 H–C(5), OH); 2.41–2.48 (*m*, 1 cyclohexyl H); 2.69 (m_c, 2 H–C(1)*); 3.06–3.34 (*m*, 2 H–C(3)*); 4.02 (br. *s*, H–C(7)). ^{13}C-NMR (75.5 MHz, $CDCl_3$, APT): 23.08 (*Me*–C(6)); 25.95 (cyclohexyl CH_2*); 26.25 (C(4)*); 27.08 (cyclohexyl CH_2*); 28.80 (cyclohexyl CH_2*); 28.92 (*Me*–C(6)); 41.48 (C(6)); 46.17 (C(5)*); 46.86 (C(1)**); 48.70 (C(3)**); 63.44 (cyclohexyl CH); 85.85 (C(7)); 134.14 (C(4a)***); 137.08 (C(7a)***). EI-MS: 249 (33, M^+), 206 (100, $[M-C_2H_5N]^+$), 193 (18, $[M-C_3H_6N]^+$), 177 (28, $[M-C_4H_{10}N]^+$), 165 (4), 133 (5), 26 (6), 84 (13), 68 (11), 53 (14), 49 (18), 41 (15, $C_3H_5^+$).
