Intramolecular participation by carboxyl group in diazotization processes has received much attention. The deamination of (R)- $\beta$ -aminoadipic acid in aqueous nitrous acid affords (S)-carboxymethylbutanolide (2) with 69% net inversion.

In connection with diazotization of L-glutamic acid which affords (S)- $\gamma$ -carboxy- $\gamma$ -butyrolactone with retention of configuration<sup>1</sup>, we have first attempted to investigate which of the  $\beta$ -carboxylate and the  $\gamma$ -one would participate more in nitrous acid deamination of (R)- $\beta$ -aminoadipic acid (1) which has the both carboxylates in one molecule.

(R)-(-)- $\beta$ -aminoadipic acid (1) was obtained by the asymmetric synthesis according to our described procedure<sup>2</sup>. Treatment of the hydrochloride of (R)-(-)- $\beta$ -aminoadipic acid  $[[\alpha]_D^{23} -18.6^\circ$  (C=1.0, H<sub>2</sub>O), e.e. 94%] with NaNO<sub>2</sub> (1.5 equiv. mole) in 3N-HCl at -4°C for 1.5 hr and then at 24°C for 4 hr followed by evaporation in vacuo to dryness and extraction of the residue with ethyl acetate gave

crude  $\gamma$ -carboxymethylbutanolide (2). Esterification with diazomethane and purification of the product by silica gel chromatography afforded (S)- $\gamma$ -methoxycarbonylmethylbutanolide (3) (11%),  $[\alpha]_D^{22} +28.8^\circ$  (C=0.4, EtOH). Treatment of the (S)-lactone (3) with hydrazine hydrate in methanol followed by Tlc purification ( $\text{SiO}_2$ , benzene-AcOEt 1:1) gave (S)- $\beta$ -hydroxyadipic acid dihydrazide (4) (30.3%), m.p. 153-155°,  $[\alpha]_D^{25} +17.2^\circ$  (C=1.0, 1N-HCl). S-configuration and 65% optical purity of the (S)-dihydrazide (4) were determined by comparing its optical rotation value with that for optically pure (S)-(+)- $\beta$ -hydroxyadipic acid dihydrazide (4),  $[\alpha]_D^{20} +26.4^\circ$  (C=1.06, 1N-HCl), derived from natural agrimonolide<sup>3b</sup>. This result corresponds to 69% net inversion in diazotization of (R)-(-)- $\beta$ -aminoadipic acid (1) based on 94% optical purity of the starting material (1). This diazotization process also constitutes a first asymmetric synthesis of (S)- $\gamma$ -carboxymethylbutanolide (2).

Scheme 1

No  $\beta$ -lactone was found in the above diazotization of (R)-(-)- $\beta$ -aminoadipic acid (1).

Intramolecular substitution of the diazonium group by the  $\beta$ -carboxylate in the deamination of (1) may lead to a  $\beta$ -lactone or (R)- $\gamma$ -carboxymethylbutanolide with retention of configuration which is formed through two consecutive reactions analogous to those proposed in diazotization of  $\alpha$ -amino acid, eg. L-phenylalanine<sup>4</sup>; (1)  $\beta$ -lactone opening by water in a back-side attack, (2) relactonization of (R)- $\beta$ -hydroxyadipic acid. However this is not the case. In conclusion the participation of the  $\gamma$ -carboxyl group is remarkably preferred than that of the  $\beta$ -carboxylate in the deamination of (R)- $\beta$ -aminoadipic acid (1), yielding (2) with 69% net inversion of configuration.

ACKNOWLEDGEMENT We wish to thank Drs. T. Noguchi and S. Ishimoto for their support.
