## Bridged Quinuclidines: Synthesis of 5-Azatricyclo[3.2.1.0<sup>2,7</sup>]octane. Incorporation of a Bridged Quinuclidine Into The Cinchona Alkaloid Skeleton <sup>1a,†</sup>

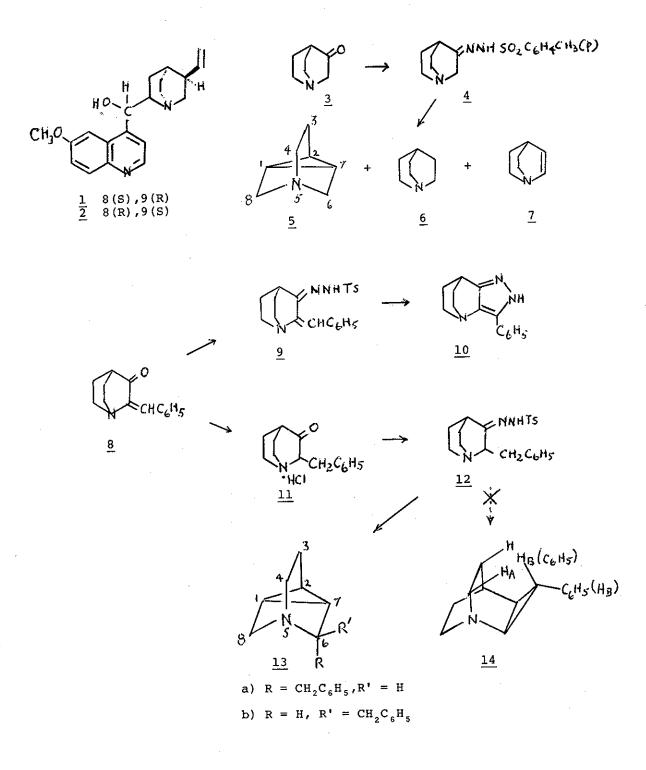

## Vlasios Georgian<sup>\*</sup> and William H. Koster <sup>1b</sup> Department of Chemistry, Tufts University Medford, Massachusetts, 02155 U.S.A.

Incorporation of a bridged quinuclidine into the cinchona alkaloid skeleton is discussed.

More than twenty years after the completion of the synthesis of quinine (1) and quinidine (2) by Woodward and Doering,<sup>2)</sup> a resurgence of interest in the chemistry of the <u>Cinchona</u> alkaloids has occurred and recently several new syntheses have been reported.<sup>3)</sup> With the emergence of resistant strains of <u>P. falciparum</u>, the antimalarial activity of quinine and its analogues is becoming more important.<sup>3)</sup> Therefore ,we were interested in synthesizing quinine analogue <u>20</u>, incorporating a bridged quinuclidine moiety such as <u>5</u> in such a manner that the vinyl feature in the <u>Cinchona</u> alkaloids would be replaced by a carbon-carbon bridge at that site.

The parent novel tricyclo base ring system 5-azatricyclo[ $3.2.10^{2}$ /<sup>7</sup>]octane (5) was synthesized by transannular carbene insertion.<sup>4</sup>) The readily available 3-quinuclidone was converted to tosylhydrazone <u>4</u> which was decomposed via the sodium salt by heating in ethylene glycol. It had been reported that under these conditions there was formed a mixture containing equal amounts

(1017)

of quinuclidine (6) and dehydroquinuclidine (7).<sup>5)</sup> However, we separated (vpc) a 12:2:1 mixture of bases 5, 6, and 7 respectively. Decomposition of the potassium salt prepared from 4 with potassium t-butoxide in refluxing diglyme gave a 9:1 mixture of 5 and 6 (69% combined yield). Isolation of 5 was facilitated with the oxalate salt, mp 168.5-170°,<sup>6)</sup> from which the desired free base 5 was obtained as an hygroscopic, low melting, volatile solid;  $v_{max}$  (neat) 3045 cm<sup>-1</sup> (cyclopropyl CH); PMR (CCl<sub>4</sub>, $\delta$ ) 0.78 (tt,  $J_{H1H2} = 8$  Hz,  $J_{H2H7} = 8$  Hz,  $J_{H2H3} = 2.5$  Hz, 1 H, H-2), 1.34 (broad d,  $J_{H1H2}$  and  $J_{H2H7} = 8$  Hz, 2H, H-1 and H-7), 1.71 (m, 2H, H-3), 2.50-2.85 (complex m, 6H, CH<sub>2</sub>N); picrate, mp 286-289° (dec.).<sup>6</sup>

Although the carbene derived from <u>4</u> was conveniently effective for synthesis of the parent ring system, derivatives substituted alpha to the carbene center present yet another potential site for insertion. Therefore, decomposition of  $\alpha$ -benzylidine and  $\alpha$ -benzyl-tosylhydrazones <u>9</u> and <u>11</u> was investigated. 2-Benzylidine-3-quinuclidone <u>8</u><sup>7)</sup> was converted into tosylhydrazone <u>9</u>, mp 218-219°(dec), decomposition of which (potassium t-butoxide, refluxing diglyme) led not to transannular insertion but to pyrazole <u>10</u> (60%) isolated as an etherate, mp 179.5-180.5°; M<sup>+</sup>, m/e 225 (C<sub>14</sub>H<sub>15</sub>N<sub>3</sub> = 225). The intermediacy of a diazoalkane in this cyclization is suggested by previous observations <sup>8)</sup> on the formation of 3(5)-phenylpyrazole from cinnamaldehyde benzenesulfonylhydrazone.

Hence, the  $\alpha,\beta$ -unsaturated ketone <u>8</u> was catalytically reduced <sup>7)</sup> and converted to hydrochloride <u>11</u>, mp 168.5-174°(dec);  $\nu_{max}$ (nujol) 2425 (broad, NH<sup>+</sup>), 1740 cm<sup>-1</sup>(C=O) as the necessary

(1019)

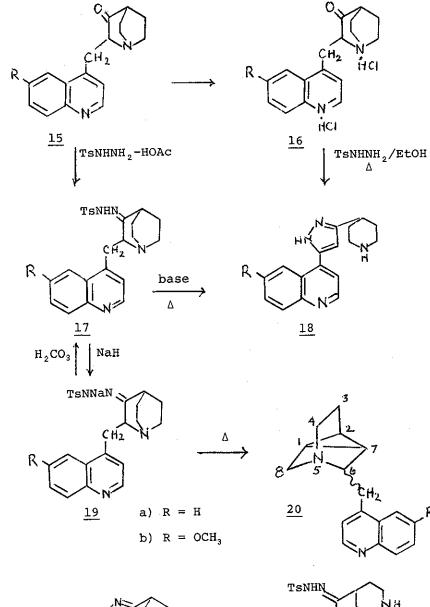

precursor to tosylhydrazone 12, mp 156-157°(dec)<sup>6</sup>, (prevention of base induced decomposition during tosylhydrazone formation). Decomposition of 12 as for the formation of 5 produced azatricyclooctane 13 in a mixture containing two dehydroquinuclidines. Silica gel chromatography afforded 13 as an oil (42% yield):  $v_{max}$  (neat) 3075(sh), 3050(sh), 3020 cm<sup>-1</sup>; PMR (CCl<sub>4</sub>, δ) 0.82 (tt,  $J_{H_1H_2}$  = 8 Hz,  $J_{H_2H_7}$  = 8 Hz,  $J_{H_2H_3}$  = 3Hz, 1 H, H-2), 1.34 (broad doublet,  $J_{H^1H^2}$  and  $J_{H^2H^7} = 8$  Hz, 2 H, H-1 and H-7), 1.42-1.77 (m, 2 H, H-3), 2.25 (q, 1 H,  $J_{gem} = 13.5$  Hz,  $J_{vic} = 8$  Hz, benzylic CH), 2.62 (q,  $J_{qem}$ = 13.5 Hz,  $J_{vic}$  = 6 Hz, benzylic CH), 2.6-3.0 (complex m, two  $CH_2N$ 's), 2.96 (q,  $J_{vic}$  = 8 Hz,  $J_{vic}$  = 6 Hz, H-6), 7.05 (m, 5 H, aromatic);  $M^+$ , m/e 199 (C<sub>14</sub>H<sub>17</sub>N = 199); picrate, mp 166.5-167.5°6). Assignment of the proton resonances in 13 was corroborated by spin decoupling. Irradiation of the H-2 multiplet at 0.82 ppm collapsed the broad H-1 - H-7 doublet at 1.34 ppm, and the vicinal couplings of the benzylic proton guartets at 2.25 ppm and 2.62 ppm collapsed upon irradiation of the H-6 quartet at 2.96 ppm. Compound 13 appeared to be only one isomer, 13a or 13b, by TLC, VPC, and PMR, but as yet it has not been possible to ascertain the C-6 configuration with certainty. However, by comparison with previous observations on several substituted tricyclo[3.2.1.0<sup>2,7</sup>]octane systems, the lack of coupling between H-6 and H-7 is strongly suggestive of the endo-7-benzyl structure 13a (exo C-6 H).  $^{9,10)}$  The formation of 13a may thence be rationalized on the basis that steric interactions (less on endo side) developing during the transition state may be responsible for giving the thermodynamically stable endo isomer.<sup>10)</sup>

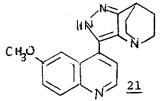

(1020)

Cyclopropano-quinuclidine <u>14</u> which would have resulted from carbene insertion into the benzylic C-H bonds was not isolated from the reaction mixture. As is evident in a molecular model of the carbene, the two benzylic protons can achieve the same attitude and distance relative to the carbenic center as the two nearest <u>syn</u> transannular protons. However it is apparent that steric interactions bewtween  $H_A$  and  $H_B$  or the phenyl ring (see structure <u>14</u>) would develop during the insertion process to inhibit the formation of 14.

Our investigations were extended to the synthesis of the analogous rubane systems 20. 3-Quinuclidones  $15a^{11}$  and 15b(mp 71.5-74°)<sup>12)</sup> as hydrochloride salts <u>16</u> on treatment with p-toluenesulfonehydrazide (refluxing ethanol/water) did not yield the expected hydrazones 17 but rather pyrazoles 18a (35%), mp 261-263<sup>O</sup> (dec)<sup>6)</sup>, PMR( $D_2O$ -DC1, internal standard DSS,  $\delta$ ) 6.67 (s, 1 H, pyrazole CH);  $\lambda_{max}^{EtOH}$  231.5 ( $\epsilon$  34,400), 309 ( $\epsilon$  10,400) 315 nm (sh,  $\varepsilon$  8,800); M<sup>+</sup>, m/e 278 (C<sub>17</sub>H<sub>18</sub>N<sub>4</sub>= 278), and 18b (22%), mp 231.5-232.5°<sup>6)</sup>;  $\lambda_{max}^{EtOH}$  205 (ε 25,700), 234 (ε 30,000), 300 ( $\epsilon$  6400) 338 nm ( $\epsilon$  6,300). The uv absorption of 18b shows a close similarity with that of the fused ring system 21;  $\lambda_{\max}^{\text{EtOH}}$ 206 ( $\varepsilon$  26,000), 233 ( $\varepsilon$  34,000), 302 ( $\varepsilon$  7,000), 338 nm ( $\varepsilon$  7,400).<sup>13)</sup> Formation of 18 was circumvented (15, p-toluenesulfonehydrazide, one equivalent acetic acid, two days at room temp.), and 17a (86%), mp 166.5-167.5°(dec) and 17b (80%), mp 165-166<sup>°</sup> (dec) were made available. Refluxing the rubane tosylhydrazones 17 in 10% aqueous potassium hydroxide also produced pyrazoles 18a (80%) and 18b (71%). Formation of the pyrazole ring system under both acidic

R

HETEROCYCLES, Vol. 7, No. 2, 1977

and basic conditions probably proceeds through  $\alpha,\beta$ -unsaturated tosylhydrazones <u>22</u> and <u>23</u>, which decompose to <u>18</u> by cyclizationelimimination (or vice versa). The reaction is related to the well known rearrangement of the <u>Cinchona</u> alkaloids to toxines.<sup>14</sup>)

Only by the decomposition of the dry sodium salts <u>19a,b</u> (<u>17</u> plus NaH) was it possible to obtain the desired bridgedquinuclidine rubanes <u>20a,b</u>. Heating <u>19a</u> as a dry powder at 310-320° gave the rubane <u>20a</u> as an oil:  $v_{max}$  (neat) 3030, 3010 cm<sup>-1</sup> (sh); PMR (CDCl<sub>3</sub>, $\delta$ ) 0.91 (tt, J<sub>H1H2</sub>=8 Hz, J<sub>H2H7</sub>= 8 Hz, J<sub>H2H3</sub>= 2.5 Hz, 1 H, H-2), 1.15-1.75 (complex m, 4 H, H-1, H-3, and H-7), 2.70-3.42 (complex m, 7H, CHN, 2 CH<sub>2</sub>N's, and CH<sub>2</sub>Ar), 7.23 (d, J=4.5 Hz, 1 H, aromatic H), 7.43-8.22 ( complex m, 4 H, aromatic H), 8.73 (d, 1 H, J=4.5, aromatic H); M<sup>+</sup>, m/e 250 (C<sub>17</sub>H<sub>18</sub>N<sub>2</sub> = 250). Decomposition of sodium salt <u>19b</u> in refluxing diglyme gave rubane <u>20b</u> (91%); mp 106.5-109°; M<sup>+</sup>, m/e 280.1574 (C<sub>18</sub>H<sub>20</sub>N<sub>2</sub>O = 280.1576).

At this time the stereochemistry at C-6 in 20a,b has not been ascertained, because the PMR spectrum does not lend itself to such an analysis as was the case for <u>13a</u>. But if the same factors and forces are operative here as in the benzyl substituted case <u>13a</u> (vide supra), and it seems reasonable that they would be, then the <u>endo</u> configuration for the quinoline moieties (<u>exo</u> C6-H) would seem to be a palpable proposal for the structures 20a,b.

Also, during the decomposition of  $\underline{17}$  dehydrorubanes are formed as evidenced by PMR, but these products were not investigated further.

We have succeeded in introducing the 5-azatricyclooctane

(1023)

ring system 5 into the <u>Cinchona</u> alkaloid skeleton by remote functionalization. Currently, the introduction of an hydroxyl function at C-9 in <u>20</u> is under investigation using oxidative methods developed for the synthesis of the <u>Cinchona</u> alkaloids.<sup>3)</sup>
