(Submitted in honor of Prof. T. Nozoe's 77th birthday)

Flash vacuum pyrolysis of 3,5-dimethyl- β -phenethylsulfonyl azide at 650° gives appreciable quantities of the normal nitrene cyclization products as well as some 2-cyclopropyl-3,5-dimethyl-pyridine. 3-Chloro- $(5\underline{\text{H}})$ - and $(7\underline{\text{H}})$ -pyrindine are obtained from 3,5-dichloro- β -phenethylsulfonyl azide. Possible mechanisms are proposed to account for the results.

The flash vacuum pyrolysis (FVP) of a number of β -phenethylsulfonyl azides has been reported and a tentative mechanism proposed for the formation of dihydropyrindines. We now describe the results obtained from the FVP of some 3,5-disubstituted β -phenethylsulfonyl azides ($\frac{1}{6}$) which necessitate some refinement in the proposed mechanism. In the final step of the latter a hydrogen migration [$\frac{2}{6}(R = H) \longrightarrow \frac{3}{6}(R = H)$] occurred from the position originally meta to the ethyl side

It was of interest, therefore, to determine whether or not such a migration would occur if the meta positions were blocked and, if not, what pathway would be followed.

3,5-Dimethyl- β -phenethylsulfonyl azide ($\frac{1}{1}$; R = Me)² underwent FVP at 400°C in a nitrogen flow (10mm Hg pressure) to give 6,8-dimethyl-3,4-dihydro-2,1-benzothiazine-2,2-dioxide ($\frac{1}{1}$; R = Me)³ (46%), mp 187-188°, 3,5-dimethylstyrene ($\frac{5}{1}$; R = Me) (3.8%)³, and 5,7-dimethyl-indoline ($\frac{6}{1}$; R = Me) (trace). As expected, FVP of $\frac{1}{1}$ at 650° gave a lower yield of $\frac{1}{1}$ (20.5%) and a corresponding larger amount of $\frac{6}{1}$ (14.8%). In addition, however, a new type of product was obtained, namely 2-cyclopropyl-3,5-lutidine ($\frac{7}{1}$; R = CH₃) (2.9%), bp 45-48°/0.05 mm; picrate, mp 154-156°(EtOH); identical with a sample prepared (49% yield) from 3,5-lutidine and cyclopropyllithium in boiling toluene. No pyrindine derivative 3 was detected.

Cyclopropylpyridine χ (R = CH₃) was stable under the FVP conditions. Reinvestigation of the FVP of β -phenethylsulfonyl azide (χ ; R = H) at 650° gave rise to a trace of a compound with the same retention time as authentic 2-cyclopropylpyridine (χ ; R = H) but the quantity formed was too small to permit collection from the g.l.c. and thus positive identification could not be made. A similar result was obtained by carrying out the FVP at 750°. χ (R = H) too was stable at 650° and did not rearrange to dihydropyrindine under FVP conditions.

In contrast, FVP of 3,5-dichloro- β -phenethylsulfonyl azide (1; R = C1), mp 79-80° (aq. EtOH), at 650° gave ξ (R = C1) (2.4%), $\frac{1}{4}$ (R = C1) (4.8%), mp 156-157° (benzene), ξ (R = C1) (2.7%), and a mixture of 3-chloro-(5H)-(ξ) and 3-chloro-(7H)-1-pyrindine (ξ), mp 58-59° (43.9% yield). No cyclopropylpyridine derivative (7)

could be detected by g.l.c..

In the tentative mechanism proposed earlier the proton migration step [2 \rightarrow 3 (R = H)] occurs at the end of the reaction sequence, long after the SO₂ is eliminated. The formation of appreciable quantities of $\frac{1}{2}$ (R = Me) [and the product 5 of its thermal decomposition at 650° when migration [2 \rightarrow 3 (R = Me)] is apparently not feasible suggests that either the 3,5-dimethyl groups stabilize the intermediate sultam considerably, thus diverting the reaction towards formation

of $\frac{1}{\sqrt{}}$ (R = Me), or loss of SO₂ occurs much later in the sequence with all the preceding steps being reversible. In the former case, the proposed scheme would have to be refined somewhat as in Scheme I below. If the latter case obtains then a possible explanation might

$$4 \stackrel{R}{\longleftarrow} 10^{SO_2} = \stackrel{R}{\longleftarrow} 10^{SO_2} \stackrel{-SO_2}{\longleftarrow} \stackrel{R}{\longleftarrow} 10^{SO_2} = \stackrel{R}{\longleftarrow} 10^{SO_2} \stackrel{-SO_2}{\longleftarrow} \stackrel{R}{\longleftarrow} 10^{SO_2} = \stackrel{$$

$$3 \stackrel{R=H,Cl}{\longleftrightarrow} 2 \stackrel{R}{\longleftrightarrow} R$$

be that outlined in Scheme 2, though again it would be necessary to assume that loss of SO₂ from $\frac{11}{\sqrt{K}}$ is rendered more difficult when R = CH₃. An intermediate such as $\frac{12}{\sqrt{K}}$ ($\frac{1}{2}$ or $\frac{1}{2}$) is required by the observation that both α - (present work) and β -methyl- β -phenethylsulfonyl azides give the same ratio of 6- to 7-methyldihydropyrindines.

SCHEME 2

$$4 \leftarrow 10 \Rightarrow R \Rightarrow SO_2 \Rightarrow SO$$

3-Chloro- $(7\underline{H})$ -1-pyrindine (2) may arise directly from 2 (R = Cl).

- 5. Nmr (CDCl₃) δ 8.39 and 8.28 (2 d, $\underline{J}_{2,4}$ = 2.5 Hz, 1H, H₂), 7.65 and 7.53 (2 d, $\underline{J}_{2,4}$ = 2.5 Hz, 1H, H₄), 7.07-6.67 (m, 2H, vinylic H), 3.60 3.30 (m, 2H, CH₂). The ratio of the peaks at δ 8.39 and 8.28, and at δ 7.65 and 7.53 changes from 3.9:1 to 1.5:1 on keeping the CDCl₃ solution with the δ 8.39 and 7.65 peaks decreasing in intensity and those at δ 8.28 and 7.53 increasing. This shows that 2 initially formed tautomerizes to 8 in solution, as reported for other $(5\underline{H})$ -1-pyrindines. δ
