PRIMARY AND SECONDARY PHOTOCHEMISTRY OF α-TROPOLONE METHYL ETHER

Dedicated to Professor T. Nozoe who did so much for the chemistry of troponoid compounds on the occasion of his 77th birthday.

Abstract The photoisomerization of  $\alpha$ -tropolone methyl ether to 1-methoxybicyclo[3.2.0]hepta-3,6-dien-2-one proceeds via the S $_1$  state. Irradiation of 1-methoxybicyclo[3.2.0]hepta-3,6-dien-2-one gives 6-methoxybicyclo[3.2.0]-hepta-3,6-dien-2-one and 7-methoxybicyclo[3.2.0]hepta-3,6-dien-2-one. The 6-methoxy product is formed via  $\alpha$ -cleavage in the T $_1$  state. The 7-methoxy product is formed in a process involving a deep-seated skeletal rearrangement. The first step in this rearrangement involves formation of cis,cis-2-methoxybicyclo[2.1.0]pent-2-en-5-yl ketene from the S $_1$  state of 1-methoxybicyclo[3.2.0]hepta-3,6-dien-2-one. The ketene intermediate is converted to 7-methoxybicyclo[3.2.0]hepta-3,6-dien-2-one by a facile Cope rearrangement which proceeds rapidly above 233K.

Irradiation of  $\alpha$ -tropolone methyl ether (1) in aqueous solution has been shown to give in sequence 1-methoxybicyclo[3.2.0]hepta-3,6-dien-2-one (2), 7-methoxybicyclo[3.2.0]hepta-3,6-dien-2-one (3), and methyl 4-oxo-2-cyclopentenylacetate (4). In it is the details of these three photochemical

processes which form the content of the present manuscript.

Irradiation (290  $\pm$  15 nm) of  $\alpha$ -tropolone methyl ether (0.01-0.10 M) in  $\underline{t}$ -butyl alcohol gives 2 with a quantum yield of 0.051 (< 2% conversion). The reaction is not quenched by di-tert-butyl nitroxide at concentrations up to 0.5 M. Attempts to photosensitize the reaction using 254 nm light and either acetophenone ( $E_{\overline{t}}$  74 kcal/mole,  $k_{ic}$   $10^{11}~sec^{-1}$ ) or benzophenone ( $E_{\overline{t}}$  69 kcal/mole,  $k_{ic}$   $10^{10}~sec^{-1}$ ) were unsuccessful. The triplet energy of  $\alpha$ -tropolone methyl ether is  $\sim$  49 kcal/mole in EPA. The negative quenching and sensitization data suggest that the formation of 2 involves orbital symmetry allowed bridging in the  $S_1$  state of  $\alpha$ -tropolone methyl ether or  $\alpha$ -trans isomerization of one of two double bonds (5 and 6) followed by orbital symmetry allowed thermal closure. The photoisomerization of 2,4,6-cyclooctatrien-1-one (7) to 8 proceeds via a

$$\begin{array}{c} CH_3O \\ \\ CH_3O \\ \\ \end{array}$$

highly strained  $\underline{\text{trans}}$ -double bond intermediate (9). A process involving a tropolone ring with a

<u>trans</u>-double bond thus must be seriously considered. The photoisomerization of  $\alpha$ -tropolone methyl ether unfortunately does not occur at low temperatures, and the methods used to observe  $\frac{9}{\alpha}$  are therefore not applicable.

The photochemical transformation of 1-methoxybicyclo[3.2.0]hepta-3,6-dien-2-one (2) to 7-methoxybicyclo[3.2.0]hepta-3,6-dien-2-one (3) involves a fascinating rearrangement. When alkyl derivatives of 2 (10-12) are irradiated, a deep-seated skeletal rearrangement is disclosed.  $^{3,4}$  It is clear from the product structures (13-15) that the bridgehead carbons exchange places with the

cyclobutene olefin carbons. This transformation is shown schematically as  $16 \longrightarrow 17$ . Irradiation of 2 at 77K reveals initial formation of an intermediate which has infrared bands characteristic

of a ketene (2118  ${\rm cm}^{-1}$ ) and an enol ether double bond (1620, 825  ${\rm cm}^{-1}$ ). Warming the intermediate above 233K, gives 3. A variety of bridged bicyclic ketones (18) give ketenes (19) by the same

process.<sup>6,7</sup> These ketenes are kinetically more stable than the ketene derived from 2, and can be characterized by nmr spectroscopy and trapping as the esters (20).<sup>6</sup> It is thus reasonable to assign structure 21 to the ketene derived from 2. Compound 21 is a <u>cis</u>-divinylcyclopropane, a bicyclo[2.1.0]pentene, an enol ether, and a ketene. The facile Cope rearrangement which transforms

$$\begin{array}{c} CH_3O \\ OCH_3 \\ CH=C=O \end{array}$$

it to  $\mathfrak Z$  is not surprising. This Cope rearrangement also accounts for the skeletal rearrangement (22-24).

$$\begin{array}{c} \text{CH}_3\text{O} \\ \text{CH} = \text{C} = \text{O} \end{array}$$

A second product is formed in the irradiation of 1-methoxybicylo[3.2.0]hepta-3,6-dien-2-one (2). This product has been identified by spectroscopy<sup>8</sup> and pyrolysis to  $\gamma$ -tropolone methyl ether as 6-methoxybicyclo[3.2.0]hepta-3,6-dien-2-one (25). A variety of photosensitizers (acetophonone,

CH<sub>3</sub>0 
$$\frac{1}{2}$$
  $\frac{1}{2}$   $\frac{1}{2}$ 

benzophenone, thioxanthone, and Michler's ketone) gave increased yields of 25 and di-tert-butyl nitroxide quenched formation of 25 (slope = 3.59) but not formation of 3. These results are consistent with the mechanism shown in Scheme I. The ketene (21) is derived from the S<sub>1</sub> state SCHEME I

of 2. Formation of 21 competes with intersystem crossing to the  $T_1$  state of 2 which cleaves to the triplet biradical 26. This biradical can give 2 or 25.

The final stage in the conversion of 1 to 4 involves a photochemical hydration of a double bond in 3. The details of this process are not known.
