THERMAL REARRANGEMENTS OF 4- AND 6-VINYL-1,2,5,6-TETRAHYDROPYRIDINE AND 2-VINYLPIPERIDINE N-IMIDES

Takashi Tsuchiya* and Haruki Sashida School of Pharmacy, Hokuriku University, Kanagawa-machi, Kanazawa 920-11, Japan

<u>Abstract</u> — The thermolysis of the 4-vinyl-1,2,5,6-tetrahydropyridine N-imide (3) resulted in both [1,2]- and [2,3]sigmatropic rearrangement to give the diazepine (4) and the pyrazole (5), respectively. This reaction mechanism was confirmed by a deuterium-labelling experiment. Whereas, in the thermolysis of the 2-vinyl derivatives (7 and 12), the [2,3]-rearrangement took place preferentially with the vinyl group to give the ring-expansion products (8 and 13).

In connection with the thermal rearrangements of various types of nitrogen¹⁻³ and sulfur^{4,5} ylides, we were interested in examining such reaction of unsaturated cyclic amine N-imides, and already reported⁶ that the thermolysis of the 1,2,5,6-tetrahydropyridine N-imides (1) resulted in the [2,3]-sigmatropic rearrangement to give the 3-vinyltetrahydropyrazoles (2). We report here the results of the thermolysis of the title cyclic amine N-imides (3, 7, and 12), which were expected to undergo different types of rearrangements from that observed for 1 because of the presence of the vinyl group.

Thermolysis of the 4-vinyl-1,2,5,6-tetrahydropyridine N-imide $(3a)^7$ in xylene at 130-140 °C for <u>ca</u>. 6 hr and chromatography on silica gel gave the 5-vinyl-1,2,5,6-tetrahydro-1,2-diazepine (4a: 25%) and the 3,3-divinyltetrahydropyrazole (5a: 30%).⁸ The formation of the ring-contraction product (5a) may involve a [2,3]-rearrangement occurred with the double bond in the ring by analogy with the case of 1.⁶ However, two possible mechanisms; i.e., [1,2]- and [2,5]-rearrangements, have been considered for the formation of the ring-expansion product (4a). Therefore, the following deuterium-labelling experiment was carried out in order to clarify this mechanism.

Thermolysis of the deuteriated N-imide (3b), prepared from 4-vinyl-N-ethoxycarbonyliminopyridinium ylide by successive NaBD₄ reduction, N-methylation, and base treatment in the manner described for 4a, yielded the labelled products (4b) and (5b), but no [2,5]-rearrangement product (6) as shown in Scheme 2.⁹ This result clearly indicates that the formation of the diazepine (4) from 3 proceeds through a Stevens-type [1,2]-rearrangement and not [2,5]-rearrangement with the vinyl group.

Next, thermolysis of the 6-vinyl N-imide $(7)^{10}$ in refluxing xylene gave the 1,2-diazacyclononadiene (8: 20-25%),¹¹ the 3,5-divinyltetrahydropyrazole (9: <u>ca</u>. 1%), and the heptatrienyl hydrazine (10: 5-6%). The reaction of 7 may involve

Scheme 3

two different $\{2,3\}$ -rearrangements to give 8 and 9, and a Hofmann-type cyclic elimination to give 11. This result shows that the [2,3]-rearrangement with the vinyl group predominates over that with the cyclic double bond. In this case, [1,2]-rearrangement products such as the 1,2-diazepine (11) could not be isolated.

Finally, the 2-vinylpiperidine N-imide $(\underline{12})$ was heated to give the [2,3]-rearrangement product $(\underline{13})^{11}$ in 75-80% yield as the sole product, analogous for the 2-vinyl derivatives of thiane⁵, and to give no [1,2]-rearrangement product.

Many studies on thermal reactions of the open chain allylic ylides $(\underline{14})$ have shown that the [2,3]-rearrangement predominates over the [1,2]-rearrangement.^{2,3} Whereas, the pentadienyl ylides ($\underline{15}$) are known to undergo the [1,2]- and the [2,5]rearrangement predominantly.³ The results of the thermolysis of 7 and 12 are consistent with those of the ylides ($\underline{14}$). However, the thermal behaviour of 3 is somewhat different from that of the open chain pentadienyl ylides ($\underline{15}$), presumably because of steric effects. Studies on the detailed mechanisms and synthetic applications of the present results to other systems are under investigation.
