<u>Abstract</u> — A synthesis of the potential intermediate of  $(\pm)$ -vindoline was achieved from the isochromanone (6), which was obtained by thermolysis of the benzocyclobutene (5).

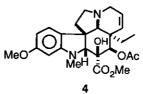

We have previously developed the tandem electrocyclic-[3,3]sigmatropic reaction of  $\underline{Z}$ - $\underline{o}$ -quinodimethanes (2), generated in <u>situ</u> by thermolysis of the benzocyclobutenes (1), as an expedient, one-pot procedure forming 4,4-disubstituted isochroman-3-ones (3).<sup>2</sup> (Scheme 1)

Scheme

Since the products thus obtained have not only a quaternary carbon at the benzylic position but also suitably functionalized structure for assembling natural products, the methodology has successfully applied to the syntheses of Calabar bean alkaloids.<sup>3</sup> In this communication we describe an alternative use of the reaction for a synthetic approach to an indole alkaloid, vindoline (4).<sup>4</sup>

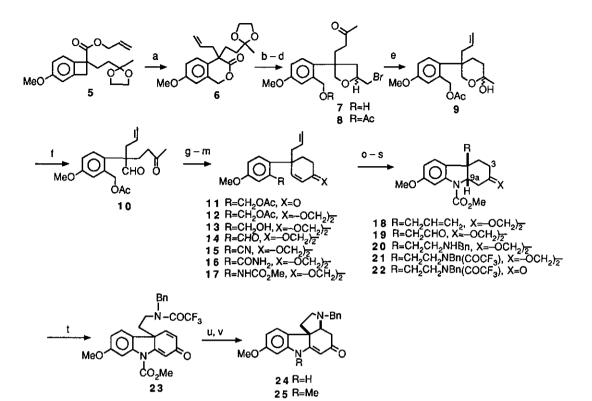

Figure

<sup>†</sup> Deceased October 11, 1988.

On heating a solution of the ally1 ester (5), prepared from 1-cyano-4-methoxybenzocyclobutene by sequential alkylation (LDA, 2-(2-bromoethyl)-2-methyl-7,3dioxolane<sup>5</sup>), hydrolysis (KOH, ag. EtOH), and esterification<sup>6</sup> (allyl alcohol, p-TsCl, 4-DMAP), in <u>o</u>-dichlorobenzene at 180°C for 8h, the isochromanone (6)<sup>7</sup> was obtained in 96 % yield. Reduction of 6 with LiAlH<sub>4</sub> gave the diol, which was treated with NBS to give the five-membered bromo ether (7) as a mixture of diastereomers. Under the reaction conditions, simultaneous hydrolysis of acetal moiety occurred. After protection of benzylic primary alcohol as the acetate, reduction of 8 with 2n-Cu couple afforded the hemiacetal (9) in 98 % yield from 6. Oxidation of 9 with PCC followed by treatment of the resulting keto aldehyde (10) with pyrrolidine and benzoic acid gave the cyclohexenone (11). Sequential acetalization and hydrolysis of 11 afforded the alcohol (13), which was oxidized with MnO, to the corresponding aldehyde (14). Transformation of the formyl group in 14 to the carbamate (17)was accomplished by the following sequence of reactions. Treatment of 14 with the conditions of oxime formation followed by immediate dehydration with carbon disulfide<sup>8</sup> afforded the cyanide (15) in 61 %overall yield from 9, which on treatment with sodium hydroxide and hydrogen peroxide gave the amide (16). The Hofmann rearrangement of 16 was carried out by the procedure of Radlick $^9$  to give the carbamate (17). Cyclization of 17 was accomplished by treatment with a catalytic amount of p-TsOH in the presence of 4  ${
m \AA}$ molecular sieves to form the tricyclic indoline (18) in 86% yield from 15. The cis stereochemistry of the ring juncture was established by H-nmr n.O.e., where irradiation of the allylic methylene protons induced 18.3 % enhancement of 9amethine proton. Oxidative cleavage of the allylic double bond of 18 afforded the aldehyde (19), which was treated with benzylamine and sodium cyanoborohydride to give the secondary amine (20). After protection of the basic nitrogen as the trifluoroacetamide, the acetal moiety of 21 was hydrolyzed to give the ketone (22) in 71 % yield from 18. With the tricyclic ketone (22) in hand, we next addressed the task of assembling the pyrrolidine ring. After numerous unsuccessful attempts to introduce a double bond at C-3 in 22 regioselectively followed by conjugate addition to construct the fourth ring, we were able to circumvent this problem by using the procedure developed by Barton.<sup>10</sup> Treatment of 22 with iodosobenzene and diphenyl diselenide in refluxing xylene gave the dienone (23)<sup>11</sup> as a 4:3 mixture of two amide rotamers in 69 % yield. Exposure of 23 to potassium carbonate in aqueous methanol gave the desired tetracyclic compound  $(24)^4$  in 93 % yield as a single product. Subsequent N-methylation with methyl iodide and sodium hydride proceeded smoothly to give 25 in 91 % yield. The structure assignment of 25 is based on spectroscopic data<sup>12</sup>, especially uv spectra, which indicate the characteristic absorption bands which agree well with those of N-acetyl derivative reported by Takano.<sup>13</sup> (Scheme 2)

## HETEROCYCLES, Vol. 28, No 1, 1989

Reagents: a)  $180^{\circ}$ C; b) LAH; c) NBS, aq. THF; d) Ac<sub>2</sub>O, pyridine; e) Zn–Cu; f) PCC; g) pyrrolidine, PhCO<sub>2</sub>H; h) ethylene glycol, *p*–TsOH; i) LiOH, aq. MeOH; v) Mel, NaH Scheme 2

In summary, a synthesis of the potential intermediate (25) for  $(\pm)$ -vindoline has been described. A further utility of the tandem methodology for the construction of Aspidosperma indole alkaloids has been exmplified.
