Abstract - From "Dragon's blood" resin (from Daemonorops draco Blume) a new biflavanoid with an unusual benzudloneplne moiety **was** isolated. Its structure **was** established by chemical and spectroscopic means. A possible mechanism of formation in the resin is proposed.

 any plants of different families produce red resins or exudates. Although they have been known for a long time in folklore or used in popular medicine, their chemical investigation started only recently, due to the complexity of their constituents.

Dragon's blood resin was formerly used in popular medicine against dysentery and as an astringent, whereas its present use **is** mostly as a varnlsh for muslcal instruments. It is most probably obtalned from fruits of Daemonorops draco **Blume** (Palmael **~n** South East **Asla.** It **was** investigated first by the schools of Brockmann 2 and Robertson and Whalley , who elucidated the structures of the red flavonoid pigments dracorhodin and dracorubin.

Investigation of the resin showed the presence of a number of other constituents $1,4-7$. particularly significant was the isolation of the two flavans (1) and (2), as they appear now to be the precursors of the whole series of biflavanoids so far found in the resin, via various l,5 "xidative **Orocesses** .

A further example of the variety of the oxldatlon pathways in the **resln is** shown by the lsolatlon of the compound (31 for whlch we propose the name dracaoxepine. This paper deals with the structural elucidation of this compound.

Dracooxepine was obtained as white crystals, mp 103-105°C, $[a]_{578}^{20} = +1,4^{\circ}$ (c 0,2; CHCl₃); uv spectrum **A** m_ 224, 271, and 302sh hm **(e** 55.300, 13,600 and 2,200). The **mass** spectrum indicated the formula C₃H₃₀⁰ (M['], m/z 538) suggesting a biflavonoid structure, while the loss of the contract the contract the contract of the loss of the contract the contract the contract of the contract of the contract of fragment with m/z 256 supported the presence of a substituted methoxyflavanol moiety . This was confirmed by treatment of (3) with diluted HCl which afforded a crystalline compound, mp 87° C,

that was shown to be identical with $(2S)$ -5-methoxyflavan-7-ol $(1)^4$.

The presence of **one** phenolic hydruxy group in the molecule **was** provided by the formation of the monoacetate (3a) (M⁺, m/z 580; C₃₅H₃₂O₈) and the monomethyl ether (3b) (M⁺, m/z 552; C_{3d}H₃₂O₇). The 1 ¹H nmr spectrum of (3a) (Table 1) showed the expected resonances for the flavan portion and the 1 ¹H nmr spectrum of (3a) (Table 1) showed the expected resonances for the flavan portion and

 a H-2" and H-6" resonate at 7.70 ppm and the remaining eight aromatic protons between 7.2 and 7.4 ppm.

b The 11, 13, 2', **3'0** , 6' 8' and 9' protons present each two signals, attributable to two diastereoisamers **(see** later), which differ between 0.001 and 0.010 ppm.

signals attributable to the protons of a pentasubstituted (A) and a monosubstituted (C) aromatic rings, to two protons on a Z-1,2-disubstituted alkene $(J_{4,5} = 8.0 \text{ Hz})$, and to one OMe, one OAc and one aromatic methyl group, resonating at δ 3.69, 2.27 and 2.06 respectively.

Table 2. - 13 C Nmr data for compound 3a in CDCl₃

 a_{The} aromatic carbons 1", 2" and 6", 3" and 5", 4" resonate at δ 137.42, 126.88, 128.42, 129.51 and 1"', 2"' and 6"', 3"' and 5"', 4"' at δ 141.56, 125.99, 128.12, 127.75.

b
Capital letters refer to the pattern resulting from directly bonded (C,H) couplings and small letters to that from (C,H) couplings over more than one-bond. S or s = singlet, D or d = doublet, $T = triplet$, Q or q = quartet, m = multiplet, and br = broad.

 c The 2, 2', 3', 4', 4'a, 5', 6', 8', 8'a, 9', 1", 1"', 2"' and 6"' carbons present each two signals, attributable to two diastereoisomers (see later), which differ between 0.02 and 0.07 ppm. The 13 C nmr spectrum confirmed and extended these findings through the appearance of 31 signals, **four** of them (C-2" and C-6", C-3" and C-5". C-2"' and C-6"', C-3"' and C-5'-') **were** clearly of twlce the intensity of the others, thus giving 35 carbon5 **in** the molecule. Chemical shift criterla and analysis of $^{1}_{H-}$ C coupling constants as corroborated by $^{13}_{C-}$ ($^{1}_{H}$) low-power specific decouplings and by one-bond 13 1 and long-range 13 C- H shift correlated 2D nmr spectra (COLOC) 8 permitted their assignment (Table 2).

From the above spectral data the following partial structure (4) could be constituted.

The substitution of ring A could be established as follows. The carbon bearing the OMe group $(C-6)$ was identified as the one resonating at 155.28 ppm by selective irradiation of the O-methyl protons, H_3 -10, which simplified the complex pattern of the C-6 signal to a quartet of doublets. The remaining three-bond couplings of 4 Hz were removed by irradiation of the 11-methyl protons and of the vinylic proton, H-5, resonating at 5.99 ppm. This fact, coupled with the observation of the presence of NOEs between H_3 -10 and H_3 -11 (2.5%) and H_3 -10 and H-5 (9%), led us to place the C-11 methyl group at C-7 and the $C(5) \approx C(4)$ double bond at C-5a. The single proton of the ring could only be allocated at C-9, since it presented three-bond couplings of 5.0 and 5.5 Hz with the $C-11$ methyl group at $C-7$ and the $C(5) \approx C(4)$ double bond at $C-5a$. The single proton of the ring could only be allocated at C-9, since it presented three-bond couplings of 5.0 and 5.5 Hz with the meta-disposed C-5a since they presented three-bond couplings with H₂-11 and H-5, respectively, and were both coupled to H-9. The OAc group must then be placed at C-8 or C-9a as H-9 underwent a downfield shift of 0.30 ppm with respect to (3) upon acetylation.

Moreover the 13 C nmr spectrum of (3a) contained the signal of a quaternary carbon at 113.11 ppm, C-2, which presented couplings of 8.5 Hz w~th **H-4 and** of 4 He wlth both H-2" and H-6". The chemical. shlft value9 suggests that it **1s** a part of an ortho ester rnalety as **shown** in **(4),** while the above (C,H) couplings not only indicate that this group is the single substituent on ring C , but also that, of the three possible OR groups of the ortho ester, one must be the $0-C(4)=C(5)H$ one. The oxygen atoms of the two remaining OR groups must then constitute the bridges between C-2 and $C-7'$ of the flavan molety (1) and between $C-2$ and $C-9a$ or $C-8$. Inspection of the Dreiding model of (4) clearly indicates that it would be impossible to link C-2 and C-8, this fact permitting us to attribute the structure **(3)** to dracouxepine.

Confirmatory evidence was provided by the following reactions. AcOH hydrolysis of the monoacetate

(3a) and hydrogenolysis of the methyl ether (3b) gave the two key compounds (5) and (6) respectively, together with the flavan (1). The presence of the 4-acetoxy and 4-methoxy groups in (5) and (6), respectively, confirms that the only free OH group in (3) must be located at C-8. The formation of (5) and (6) can be explained if the starting compound (3) contains the ortho ester

Scheme

function shown; this formulation **is** completely consistent with the **mass** spectrum, which requires seven oxygen atoms, with the presence of a cis CH=CH(O) fragment, with the absence of C=O absorption in the ir spectrum, and with the chemical shift of the quaternary carbon (C-2) in the 13 C nmr spectrum.

A possible mechanism of formation of the unusual compound (3) is shown in the Scheme. This ~xidatlve PTOCBSS, which must have occurred in the **resln,** follows the pathway already proposed by Jurd $\frac{10}{10}$ in 1966 for the H₂O₂ oxidation of flavylium salts, where a structure similar to (3) was postulated as an intermediate. In our case, the dioxepinium ion is trapped by the other flavan unit. The dissymmetric dimeric structure of (3) can be explained on the basis of the ascertained easier oxidation of the methyl-substituted flavan (2) with respect to the nor-compound (1) $^{\rm 1}$. The mechanism would also require a non-stereospecific formation of the asymmetric center at C-2. Although we have not been able to see more than one peak in the hplc of (3), the fine splitting of some signals in the ¹H and ¹³C nmr spectra of (3) lends support to the hypothesis that (3) is indeed a mixture of two diastereoisomers.

EXPERIMENTAL

All melting polnts are uncorrected. Uv spectra were measured for salutlons in 95% EtOH on a JASCO Uvidec 510 spectrophotometer; ir spectra were taken with a Perkin-Elmer 177 instrument. Nmr spectra were recorded on a Bruker CXP-300 spectrometer using TMS as an internal standard; ms were measured wlth a VG-ZAB2 **mass** spectrometer.

Isolation procedure---We have already reported the extraction procedure from the resin to obtain several flavanoid the **rsolatlon** of the **mmor** compound I31 **was** carrred out during the same chromatographic separation. Compound (3) was detected on tlc plates (Bakerflex IB-2F) by spraying with cerium(IV) in sulphuric acid (red colour on heating); Rf 0.3 in hexane- EtOAc (3:1) and 0.7 in CH_2Cl_2 -MeOH (30:1), respectively.

<u>Dracooxepine (3)</u>---Mp 103-105°C, $\lbrack \alpha \rbrack_{578}^{20}$ = +1.4° (c 0.2; CHCl₃); (Found: C, 73.4; H, 5.7; C₃₃^H₃₀^O7 requires C, 73.6; H, 5.6%), ms (m/z) : 538 (M^+) , 360, 283.0993 (calcd for $C_1H_0O_4$ 283.0970 \pm 0.002). 256.1095 (calcd for $C_{16}H_{16}$ 3, 256.1099 \pm 0.003), and 152. ¹H-Nmr(ϕ , CDC1₃): 7.72 (2H, rn. H-2" and H-6"l, 7.2-7.5 i8H. m, Phl, 6.44 (IH, d. J=8.0 Hz, H-41, 6.41 (IH, br **s.** H-91, 6.12 $(1H, d, J=2.2 Hz, H=8')$, 5.96 $(1H, d, J=8.0 Hz, H=5)$, 5.86 $(1H, br d, J=2.2 Hz, H=6')$, 4.90 $(1H, b, J=2.2 Hz)$ br dd, J=9.5 and 2.5 Hz, H-2'), 3.69 (3H, s, H₃-10), 3.55 (3H, br s, H₃-9'), 2.9-1.8 (4H, m, H_{2} -3' and H_{2} -4'), and 2.13 (3H, br s. H_{3} -11).

~~~~~~~t~ld~~~~~~~~ine (3al---Acetylation IAc 0-pyrldlne) of compound 3 gave the **monoacetate** 3a, 2 mp 104-107°C;  $\left[a\right]_{n}^{\Delta l}$  = -4.7° (C 0.2; CHCl<sub>3</sub>); (Found: C, 72.2; H, 5.7; C<sub>35</sub>H<sub>32</sub>O<sub>8</sub> requires C, 72.4; H, 5.6%); ir (KBr) (  $\mathbf{v}$  max cm<sup>-1</sup>): 1770 (Ac band), 1640, and 1600; uv (  $\lambda$  max, nm): 266 and 299 sh (  $\epsilon$  12,400 and 1,200); ms(m/z): 580 (M, 14%), 325(100), 283(64), 256(181, and 1051361. 'H and 13c-nmr data are collected **in** Tables 1 and 2 respectively.

Monomethyldracooxepine (3b)---Methylation (MeI, K<sub>2</sub>CO<sub>2</sub>, acetone) of compound 3 gave the monomethyl ether 3b, mp 83-85°C; (Found: C, 73.6; H, 5.7; C<sub>34</sub>H<sub>32</sub>O<sub>7</sub> requires C, 73.9; H, 5.8%); uv ( $\lambda$ max, nm): 272, 280sh, and 300sh (  $\epsilon$  10,000, 8,600, and 1,500); ms(m/z): 552( $\texttt{M}^+$ ), 360, 343, 297, 281, 270, and 256.

Hydrolysis of compound  $(3a)$ --- $(3a)(50 mg)$  was kept with AcOH  $(3 ml)$  at 70°C for 2 h. Evapn of the solvent gave, after preparative tlc (hexane EtOAc, 2:1), two main compounds 1 and 5; the (2S)-flavan 1 was identified by direct comparison with an authentic sample<sup>4</sup>;  $\left[a\right]_R^{20} = -6.2^\circ$  (lit.<sup>4</sup> -6.3°). The same compound 1 could be isolated when dracooxepine 3 was treated with a mixture of MeOH-HCl (9:1) for 20 h at room temperature. 5, viscous oil, has ir (CHCl<sub>2</sub>)(  $\nu$  max cm<sup>-1</sup>): 1770(Ac), 1740 and 1730 (ArCOO- and RCHO);  $ms(m/z)$ :  $342(M^{+})$ ,  $324(M^{-1}-18)$ ,  $282(324-Ac)$ , 267, 220, 205, 191, 178, and 177(282-COPh).  $^{1}$ H-Nmr (  $\delta$ , CDCl<sub>3</sub>): 9.66 (1H, t, J = 3 Hz, CHO), 8.13 and 7.54 (5H, m, PhCO<sub>2</sub>), 6.71 (1H, br s, ArH), 3.74 (3H, s, OMe), 3.64 (2H, d, J=3Hz, CH<sub>2</sub>), 2.33 (3H, s, OAc), and 2.16 (3H, br s, ArMe).

Hydrogenolysis of compound (3b) --- (3b) (50 mg), dissolved in EtOAc-MeOH (1:1) (5 ml) was reduced for 20 h with 10% Pd on BaSO<sub>4</sub> (25 mg) to obtain compound 6 together with the flavan 1; 6 was successively isolated ( $Ac_00$  - Pyridine) as the acetate 6a.

(6)  $M/z$ : 212( $M^+$ ), 194( $M^+$  - 18), 181, 165, 151, and 136.

 $^{1}$ H-Nmr (  $\delta$  , CDCl<sub>3</sub>): 6.34 (1H, br s, ArH), 3.97 (2H, m, CH<sub>2</sub>OH), 3.78 and 3.66 (6H, s, 2 OMe), 2.92 (2H, m, ArCH<sub>2</sub>), and 2.08 (3H, br s, ArMe).

(6a) 0il, ms(m/z): 254 (M<sup>+</sup>); <sup>1</sup>H-nmr(  $\delta$ , CDCl<sub>3</sub>): 6.39 (1H, br s, ArH), 4.17 (2H, m, CH<sub>2</sub>OH), 3.78 and 3.73 (6H, s, 20Me), 2.82 (2H, m, ArCH<sub>2</sub>), 2.33 and 2.03 (6H, s, 2 OAc), and 2.12 (3H, br s, ArMe).
