# USE OF CHIRAL AMIDALS IN THE SYNTHESIS OF 6-METHYLPERIHYDROPYRIMIDIN-4-ONES, PROTECTED FORM OF $\beta$ -AMINO ACIDS

Rosa Amoroso, Giuliana Cardillo\*, and Claudia Tomasini

Dipartimento di Chimica "G. Ciamician" Università di Bologna Centro per lo Studio della Fisica delle Macromolecole via Selmi 2 - 40126 Bologna - Italy

<u>Abstract</u> - The synthesis of 6-methylperihydropyrimidin-4-ones (7a and 7b) is described by mercury cyclization of the  $\beta$ , $\gamma$ -unsaturated amidal (3). After reduction of the intermediate organomercury compound (6) and separation of the diastereomeric mixture, the perihydropyrimidin-4-ones (7a and 7b) have been obtained. Their structure has been fully characterized by means of <sup>1</sup>H nmr spectroscopy and, after acid hydrolysis, the 3-aminobutyric acids (8a and 8b) have been obtained.

Perihydropyrimidin-4-ones are interesting heterocyclic compounds that represent protected forms of  $\beta$ -amino acids and are chiral precursors for the asymmetric synthesis of  $\alpha$ -substituted- $\beta$ -amino acids.<sup>1</sup> The synthesis of  $\beta$ -amino acids is receiving growing interest, due to the importance of these compounds either as components of natural products or as starting material for biological active molecules.<sup>2</sup>

Earlier work in our laboratory <sup>3</sup> showed the utility of mercury promoted cyclofunctionalization of  $\alpha$ , $\beta$ -unsaturated amidals containing as a chiral source the (*S*)-phenylethylamine in the synthesis of 5-substituted imidazolidin-4-ones, precursors of enantiomerically pure  $\alpha$ -amino acids.

Utilising the same strategy, we envisaged a new synthesis of the 6-methylperihydropyrimidin-4ones (7a and 7b), precursors of the (S)- and (R)-3-aminobutyric acids (8a and 8b), starting from the amidal obtained from the reaction of hexahydrotriazine (1) and 3-butenoyl chloride.<sup>4</sup> It is known in fact that reaction of hexahydrotriazines with acyl chlorides affords the corresponding *N*-chloromethyl adducts in quantitative yield.<sup>5</sup> Thus by treatment of 1 with 3-butenoyl chloride, the adduct (2) is obtained in quantitative yield and transformed in situ into the corresponding amidal (3) by reaction with ammonia. Compound (3) is then protected with benzyloxycarbonyl chloride to give 4 in 85% overall yield from 1. The adduct (4) is practically pure and can be utilized for further transformations. On the other hand the purification on silica gel chromatography occurs with partial decomposition (Scheme 1).

The addition of Hg(TFA)<sub>2</sub> (1.1 equiv.) to a solution of 4 in dry CH<sub>2</sub>Cl<sub>2</sub> at 0 °C promotes the cyclization.<sup>6</sup> Under these conditions the reaction monitored with tlc chromatography shows the presence of starting 4 even after prolonged reaction times. On the contrary the cyclization in MeCN with 1.1 equivalents of dry Na<sub>2</sub>CO<sub>3</sub> is complete in 2 hours.<sup>7</sup>

As the reductive removal of mercury performed on compound (5) affords 7 in low yield, 5 has been reacted with NaBr (1 equiv.) in MeOH to afford 6 in quantitative yield.<sup>7</sup> By treatment of 6 with LiBH<sub>4</sub> (1.1 equiv.) in THF at -78 °C and after the usual work-up, a mixture of 6-methylperihydropyrimidin-4-ones (7a and 7b) is obtained in 70% yield and 63:37 diastereometric ratio, as shown by the nmr spectra and by GCms (gas chromatography - mass spectrometer) analysis.<sup>8</sup> The separation of 6-methylperihydropyrimidin-4-ones (7) by flash chromatography on silica gel, affords pure 7a ([ $\alpha$ ]<sub>D</sub> -71.6°, c = 0.7, CHCl<sub>3</sub>) and 7b ([ $\alpha$ ]<sub>D</sub> -34.2°, c = 1.4, CHCl<sub>3</sub>) in the above reported diastereometric ratio (Scheme 2). The ir absorption at 1650 cm<sup>-1</sup> is diagnostic for the expected six-membered ring formation.

350

The structure of **7a** and **7b** has been established by detailed <sup>1</sup>H nmr studies. Two factors are peculiar for the determination of the configuration and of the conformation that these mobile molecules assume. As already observed <sup>9</sup> for heterocycles containing a (*S*)-phenylethylamide moiety, the chiral group on  $C_1$ ' shows a strong tendency to assume a rigid conformation with the hydrogen eclipsing the carbonyl group. In this conformation the hydrogen in front of the phenyl group is strongly shielded. Moreover the carbonyl of the protecting carbobenzoxy group deshields preferentially the hydrogen lying in the same plane, thus H<sub>a</sub> or H<sub>b</sub>, depending on the conformation of the perihydropyrimidin-4-one (see Figure 1 and Figure 2).

The presence of the carbobenzoxy group is also responsible for the formation of rotamers, which can be observed recording the <sup>1</sup>H nmr spectra at -30 °C.<sup>10</sup> While the <sup>1</sup>H nmr spectra of **7a** and **7b** show a bad resolution at room temperature, due to the coalescence point of the molecule, they show a perfect resolution, if recorded at 50 °C.

The <sup>1</sup>H nmr spectrum of the less polar isomer (**7a**) shows that the hydrogens H<sub>d</sub> and H<sub>e</sub>, resonating at  $\delta$  2.32 and 2.71 respectively, have a large geminal coupling constant ( $J_{Hd,He}$  = 15.7 Hz) and two coupling constants ( $J_{Hd,He}$  = 8.2 Hz;  $J_{He,He}$  = 6.4 Hz) that are in line with the methyl group in the equatorial position. Moreover the doublet at  $\delta$  4.14 (J = 13.2 Hz) is very shielded: this result suggests that it experiences the presence of the phenyl group, and therefore is attributed to H<sub>a</sub>. Furthermore H<sub>b</sub> ( $\delta$  4.91, J = 13.2 Hz) results deshielded by the carbonyl group lying in the same plain. These results agree with a (1'*S*,6*R*)-7a configuration in the preferential conformation reported in Figure 1.

The results of NOE experiments performed on **7a** confirm the stereochemical assignment. Thus the irradiation of the methyl at C<sub>1</sub>' ( $\delta$  1.47) produces an enhancement of the doublet at 4.91, that is therefore assigned to H<sub>b</sub>. On the other hand the irradiation of the dd at  $\delta$  2.32 attributed to H<sub>d</sub> produced an enhancement of the H<sub>a</sub> signal ( $\delta$  4.14) and an enhancement of the methyl at C<sub>6</sub> ( $\delta$  1.20). Irradiation of H<sub>e</sub> ( $\delta$  2.71) produces an enhancement of the H<sub>c</sub> signal at  $\delta$  4.20 and a very weak enhancement of H<sub>b</sub> ( $\delta$  4.91). The irradiation of H<sub>b</sub> and of the methyl at C<sub>6</sub> confirm these results.

In a similar way the structure of **7b** has been established by means of <sup>1</sup>H nmr analysis. In fact the coupling constants of H<sub>d</sub>-H<sub>c</sub> and H<sub>e</sub>-H<sub>c</sub> (J<sub>Hd,He</sub> = 15.7 Hz, J<sub>Hd,Hc</sub> = 6.3 Hz, J<sub>He,Hc</sub> = 6.6 Hz) account for a rather flat conformation with the methyl in the equatorial position. The structure of (1'S,6S)-7b is therefore forced in the conformation shown in Figure 2. The chemical shifts of H<sub>a</sub> ( $\delta$  4.74) and H<sub>b</sub> ( $\delta$  4.54) agree with this assignment: in this conformation H<sub>a</sub> is strongly deshielded

by the carbonyl of the carbobenzoxy protecting group and it does not suffer the shielding effect of the vicinal phenyl group. These effects account for the H<sub>a</sub> chemical shift at low field.

The NOE experiments performed on 7b confirm the attribution and show that the irradiation on H<sub>e</sub> causes an enhancement of the methyl on C<sub>6</sub> ( $\delta$  1.47) and of the doublet resonating at  $\delta$  4.54, that . can be attributed to H<sub>b</sub>. The irradiation of the methyl on C<sub>6</sub> causes the enhancement of H<sub>e</sub>, and the irradiation of H<sub>d</sub> causes an enhancement of H<sub>c</sub> and a weak enhancement (~1%) of the doublet resonating at  $\delta$  4.74 that can be attributed to H<sub>a</sub>. The NOE experiment performed on H<sub>a</sub> and H<sub>b</sub> confirm the above reported results. Finally the irradiation of the methyl on C<sub>1</sub>' causes a very weak enhancement of H<sub>a</sub> and H<sub>b</sub>. These results allow to attribute the conformation of (1'S,6S)-7b as reported in Figure 2.

#### Figure 2

The absolute configuration of these perihydropyrimidin-4-ones is confirmed by conversion of (1'S,6R)-7a and (1'S,6S)-(7b) into the corresponding 3-aminobutyric acids ((R)-(-)-8a and (S)-(+)-8b). In fact 8a and 8b are obtained by acid hydrolysis of 7a and 7b respectively in 6M HCI at reflux. The  $\beta$ -amino acids are purified by treatment with aqueous sodium carbonate followed by extraction with ethyl acetate to separate the (S)-phenylethylamine. Acidification of the aqueous layer and elution of the mixture from a cation exchange resin (BIORAD AG 50W-X2) with 1.5M NH<sub>4</sub>OH affords pure (8a and 8b) that show [ $\alpha$ ]<sub>D</sub> and mp values in agreement with those reported in the literature (Scheme 3).<sup>11</sup>

In conclusion the presence of the (S)-phenylethylamide molety is useful in the determination of the structure of such complex heterocycles and this work represents a simple route to the synthesis of (S)- and (R)-6-methylperihydropyrimidin-4-ones.

### EXPERIMENTAL

**General Methods.** <sup>1</sup>H Nmr and <sup>13</sup>C nmr spectra were recorded at 300 MHz and 75 MHz, respectively, on a Varian Gemini 300 spectrometer. Chemical shifts are reported in ppm relative to the solvent. The nmr tubes containing samples of **7a** and **7b** have been degased with the freezepump-thaw technique before running NOE experiments. Ir spectra were recorded with a Perkin-Elmer 682 infrared spectrophotometer. Melting points were determined in open capillaries and are uncorrected. GCms analyses were performed with a cross linked methyl silicone column. Flash chromatography was performed with silica gel 60 (230-400 mesh). Methylene chloride was distilled over CaH<sub>2</sub> and stored over molecular sieves. Tetrahydrofuran (THF) was distilled from sodium benzophenone ketyl. Other solvents were used as purchased. (*S*)-1-Phenylethylamine was purchased by Janssen and distilled.

### (S)-N-(1-Phenyleth-1-yl)-N-benzyloxycarbonylaminomethyl-acrylamide 4

A solution of 3-butenoyl chloride (2.5 g, 24 mmol) in dry  $CH_2Cl_2$  (10 ml) was added dropwise to a solution of hexahydrotriazine 1 (3.2 g, 8 mmol) in dry  $CH_2Cl_2$  (30 ml) at 0 °C and under argon. After 20 min at 0 °C the tlc analysis of the reaction mixture showed a single spot corresponding to the *N*-chloromethyl-*N*-(*S*)-phenylethylamide (2).

Meanwhile in a 500 ml four-necks flask dry  $CH_2CI_2$  (200 ml) was saturated with gaseous NH<sub>3</sub>. The solution of *N*-chloromethyl-*N*-(*S*)-phenylethylamide (2) (24 mmol) in  $CH_2CI_2$  was added dropwise at 0 °C, bubbling NH<sub>3</sub>. After 20 min a white precipitate (ammonium chloride) was formed and the bubbling was stopped. The mixture was filtered and the white solid was washed with  $CH_2CI_2$ . The liquid was concentrated under vacuum and the corresponding *N*-aminomethyl-*N*-(*S*)-phenylethylamide (3) was obtained in quantitative yield.

To a solution of *N*-aminomethyl-*N*-(*S*)-phenylethylamide **3** in CH<sub>2</sub>Cl<sub>2</sub> (50 ml) and aqueous NaHCO<sub>3</sub> (50 ml), benzyl chloroformate (2.55 ml, 18 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (10 ml) was added dropwise at 0 °C. The mixture was stirred 10 min at room temperature then separated in a funnel. The organic layer was dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated. The amidal (4) was obtained practically pure in 85% yield and could be used without any further purification. Silica gel chromatography (cyclohexane:ethyl acetate 8:2) afforded pure 4 (5.07 g, 60%), owing to partial decomposition of the amidal to the corresponding N-(*S*)-phenylethylamide.

v<sub>max</sub> (film): 3420, 3300, 1720, 1640, 1600 cm<sup>-1</sup>;  $\delta_{H}$  (CDCl<sub>3</sub>) 1.70 (3H, d, J = 7.1 Hz, N-CH-C<u>H</u><sub>3</sub>), 3.28 (2H, d, J = 6.5 Hz, OC-C<u>H</u><sub>2</sub>-CH), 4.52 (2H, m, N-CH<sub>2</sub>-N), 5.12 (5H, m, OC<u>H</u><sub>2</sub>Ph + CH=C<u>H</u><sub>2</sub> + N-C<u>H</u>-CH<sub>3</sub>), 6.05 (2H, m, C<u>H</u>=CH<sub>2</sub> + NH), 7.32 (10H, m, Ph);  $\delta_{C}$  (CDCl<sub>3</sub>) 18.12, 38.54, 49.88, 54.97, 66.27, 117.99, 126.45, 127.41, 127.56, 127.72, 128.14, 128.46, 136.17, 139.68, 155.13, 172.32; [ $\alpha$ ]<sub>D</sub> -76.5 ° (c = 2, CHCl<sub>3</sub>). Anal. Calcd for C<sub>21</sub>H<sub>24</sub>N<sub>2</sub>O<sub>3</sub>: C, 71.57; H, 6.86; N, 7.95. Found: C, 71.48, H, 6.82, N, 7.90.

## 1-Benzyloxycarbonyl-3-(1'-phenyleth-1'-yl)-6-methylperihydropyrimidin-4-ones 7a and 7b

To a stirred solution of amidal 4 (1.06 g, 3.0 mmol) in dry  $CH_2CI_2$  (60 ml) Hg(TFA)<sub>2</sub> (1.36 g, 3.2 mmol) was added at room temperature and under argon. After 2 h the reaction was complete and NaBr (0.33 g, 3.2 mmol) in MeOH (10 ml) was added dropwise. After 20 min the mixture was concentrated and replaced with dry THF (100 ml). The solution was cooled at -78 °C and LiBH<sub>4</sub> (2M solution in THF, 1.5 ml, 3 mmol) was added. The mixture was stirred overnight and the reaction mixture was allowed to warm up. Elemental mercury precipitated and was filtered, the solution was concentrated under vacuum, water and ethyl acetate were added and the organic layer was separated, dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated under vacuum. The crude was chromatographed on silica gel (cyclohexane:ethyl acetate 9:1) and the perihydropyrimidin-4-ones 7a (0.46 g, 44%) and 7b (0.27 g, 26%) were obtained.

(1'S,6*R*)-7a: mp 110-112 °C;  $v_{max}$  (nujol): 1710, 1650 cm<sup>-1</sup>;  $\delta_H$  (CDCl<sub>3</sub>, 50 °C) 1.20 (3H, d, J = 6.3 Hz, OC-CH<sub>2</sub>-CH-CH<sub>3</sub>), 1.47 (3H, d, J = 7.1 Hz, N-CH-CH<sub>3</sub>), 2.32 (1H, dd,  $J_{Hd,Hc} = 8.2 \text{ Hz}$ ,  $J_{Hd,He} = 15.6 \text{ Hz}$ , H<sub>d</sub>), 2.71 (1H, dd,  $J_{He,Hc} = 6.4 \text{ Hz}$ ,  $J_{He,Hd} = 15.6 \text{ Hz}$ , H<sub>e</sub>), 4.14 (1H, d,  $J_{Ha,Hb} = 13.2 \text{ Hz}$ , H<sub>a</sub>), 4.20 (1H, m, H<sub>c</sub>), 4.91 (1H, d,  $J_{Hb,Ha} = 13.2 \text{ Hz}$ , H<sub>b</sub>), 5.12 (2H, AB, O-CH<sub>2</sub>-Ph), 5.83 (1H, q, J = 7.1 Hz, N-CH-CH<sub>3</sub>), 7.27 (10H, m, Ph);  $\delta_C$  (CDCl<sub>3</sub>, 50 °C) 16.33, 20.55, 39.66, 47.07, 50.01, 51.91, 67.64, 127.23, 127.65, 128.06, 128.28, 128.58, 128.66, 136.21, 139.98, 168.86; [ $\alpha$ ]p -71.6 ° (c = 0.7, CHCl<sub>3</sub>); ms(m/z) 353 (1.1%), 352 (M<sup>+</sup>) (4.7%), 261 (2.7%), 247 (3.9%), 203 (2.7%), 174 (1.4%), 157 (13.1%), 120 (18.9%), 105 (26.5%), 91 (100%), 79 (7.4%), 77 (11.1%), 65 (11.1%), 56 (20.9%). ### (R)-(-)-3-Aminobutyric acid 8a

A solution of perihydropyrimidin-4-one (7a) (0.35 g, 1 mmol) in 6M HCl (5 ml) was refluxed for 12 h. The mixture was then concentrated and extracted with ethyl acetate/aqueous Na<sub>2</sub>CO<sub>3</sub> to separate the (*S*)-1-phenylethylamine. To the aqueous layer 6M HCl was added until acid pH, concentrated and replaced with water. The mixture was adsorbed on cation exchange resin BIORAD AG 50W-X2 and the resin was washed with distilled H<sub>2</sub>O till the washing came out neutral, then with NH<sub>4</sub>OH 1.5M to recover the  $\beta$ -amino acid. Evaporation of the aqueous solution

afforded the 3-aminobutyric acid (8a) in the zwitterionic form (70 mg, 68%). mp 210-211 °C (lit., <sup>11</sup> 212 °C);  $\delta_{H}$  (D<sub>2</sub>O) 1.11 (3H, d, J = 6.6 Hz, N-CH-C<u>H<sub>3</sub></u>), 2.28 (2H, d, J = 7.1 Hz, OC-C<u>H<sub>2</sub>-CH</u>), 3.40 (1H, m, CH<sub>2</sub>-C<u>H</u>-CH<sub>3</sub>);  $\delta_{C}$  (D<sub>2</sub>O) 17.26, 40.24, 44.97, 177.61; [ $\alpha$ ]<sub>D</sub> -38.1° (c = 0.7, H<sub>2</sub>O).

### (S)-(+)-3-Aminobutyric acid 8b

The  $\beta$ -amino acid (8b) was obtained from 7b with the same procedure (65% yield). mp 209-211 °C (lit., <sup>11</sup> 212 °C); [ $\alpha$ ]<sub>D</sub> +37.8° (c = 0.1, H<sub>2</sub>O), lit., <sup>11</sup> [ $\alpha$ ]<sub>D</sub> +38.8° (c = 0.48, H<sub>2</sub>O).
