SYNTHESES OF 1-HYDROXYTRYPTAMINES AND SEROTONINS HAVING FATTYAC-YL OR (E)-3-PHENYLPROPENOYL DERIVATIVES AS A N & SUBSTITUENT, AND A NOVEL HOMOLOGATION ON THE 3-SUBSTITUENT OFTHE I-HYDROXYTRYPTA-MINES UPON TREATMENT WITH DIAZOMETHANE¹

Abstract- 1 -Hydroxytryptamines (6a-f) having (Epphenyl-, (Q-3-(4-hydroxyphenyl)., **(0-3-(4-hydroxy-3-methoxyphenyl)propenoyl,** octanoyl, hexadecanoyl, and docosanoyl group as a Nb-substituent are prepared for the first time. Preparations of serotonins (2a-c, **e)** from the corresponding 1-hydroxytryptamines (6a-c, e) are also reported. A novel homologation on the 3-substituent of 1-hydroxytryptamines is discovered upon treatment with diazomethane in chloroform or dichloromethane.

Serotonins (A) and tryptamines (B) are biologically important amines.² As shown in Scheme 1, we have chemically correlated^{2d} A with B through 1-hydroxytryptamines² (C) as the intermediates which undergo nucleophilic substitution reactions selectively at the 5-position.² Whether the reaction pathway is operating in vivo still remains to be investigated.^{2a,b} We have also discovered that 1-hydroxyindoles have potent anti-blood platelet aggregation activity.³

On the other hand, Nb-fattyacyltryptamine derivatives (1, Scheme 2) were isolated from the seeds of Annona reticulata by Maeda and co-workers.⁴ Sakakibara and co-workers reported serotonin derivatives (2a,b) as antioxidants from sufflower (Carthamus tinctorius L.) oil cake.⁵ These facts prompted us to design both 1-hydroxytrypta-

mines **(6a-f)** and serotonins **(2a-c, e)** having fattyacyl or (E)-3-phenylpropenoyl derivatives as a Nb-substituent in order to develop a new inhibitor of blood platelet aggregation. Furthermore, an interesting theme is to determine whether the above synthetic methodology shown in Scheme 1 is applicable for their preparations without forming kabutanes and dimers. 2C

Now, we wish to report syntheses of the target compounds and also describe anew homologation on the side chain at the 3-position upon treatment with CH₂N₂ which is characteristic to 1-hydroxyindole structure.

The reaction of tryptamine (3) with octanoic chloride, hexadecanoic chloride, and docosanoic anhydride afforded the corresponding amides **(4d-1)** in 48, 95, and 92% yields, respectively. Reduction of 4d-1 with Et₃SiH⁶ in tri-

Scheme 2

fluoroacetic acid (TFA) afforded 2,3-dihydroindoles (5d-f) in 96, 98 and 91% yields, respectively. Subsequent 1hydroxyindole syntheses from 5d-f by the reaction with Na₂WO₄.2H₂O and 30% H₂O₂^{2,7} were successfully realized by changing the original solvent system^{2,7} (MeOH-H₂O) to CHC₃-MeOH-H₂O resulting in the formation of 6d-fin 77, 62, and 79% yields, respectively. Similarly, (E)-Nb3-(4-hydroxyphenyl)- (4a), (E)-3-(4-hydroxy-3methoxyphenyl)- (4b), and (E)-3-phenylpropenoyltryptamine (4c) were produced in 71, 73, and 97% yields, respectively. Although their reduction with Et₃SiH in TFA gave poor results, NaBH₃CN⁸ in AcOH was the reagent of choice to produce 5a-c in 85, 82, and 83% yields, respectively. In the cases of 5a-c, application of 1-hydroxyindole syntheses with Na₂WO₄.2H₂O and 30% H₂O₂ in MeOH-H₂O was successful giving 6a-cin 57, 44, and 63% yields, respectively.

The expected regioselective nucleophilic substitution took place in the reaction of 6e with 85% HCOOH²,⁷ at room temperature to afford Nb-hexadecanoylserotonin (2e) and its 1-formyl derivative (7e) in 42 and 22% yields, respectively. Similar reaction of 6c produced 2c and 7c in the respective yields of 33and 8%. Syntheses of natural products (2a and 2b) were attained in 5 and 16% yields, respectively, by the treatment of 6a and 6b with 85% HCOOH, though the optimum reaction conditions are not made yet.

The structures of 2a and 2b were proved unequivocally by direct comparison with the authentic samples which were obtained in 79 and 99% yields, respectively, by reacting authentic serotonin (2g), prepared according to our procedure^{2d} with (E)-3-(4-hydroxyphenyl)- and (E)-3-(4-hydroxy-3-methoxyphenyl)propenoic acid in the presence of DCC and 1 -hydroxybenzotriazole.

Generally, the structure of 1-hydroxyindole is confirmed by converting it to the corresponding 1-methoxyindole by the reaction with CH₂N₂ in MeOH. Since the solubility of 6e in MeOH was poor, it reacted in CH₂CI₂ at room temperature. Unexpectedly, generation of an abnormal product (9e) was observed in 23% yield in addition to 62% yield of the normal 1-methoxyindole (8e). Abnormal products were similarly observed in the reactions of 6d, 6f, and 6h with CH₂N₂ in CHCI₃ or CH₂CI₂. For example, the reaction of 6h in CHCI₃ produced 8h, 9h, and two unknown products (molecular weights are 230 and 269, respectively) in the respective yields of 36, 9, 15, and 5% yields. In MeOH, however, all compounds (6d, 6e, 6f, and 6h) afforded normal products (Ed. 8e, 8f, and ah), exclusively. The structures of 9d-f, h were proved as follows. As a representative of abnormal products, 9h was catalytically hydrogenated with 10% Pd/C to remove 1-methoxy group giving 10 in a quantitative yield. Reduction of 10 with LiAIH4 afforded Methyl-3-(indol-3-y1)propylamine (1 1) in 64% yield. On the other hand, authentic 3-indolepropionic acid (12) led to the corresponding ethylamide (13) in 98% yield by the mixed anhydride method using methyl chloroformate and ethylamine. Subsequent reduction of 13 with LiAIH₄ produced 91% yield of the

authentic 11, which was identical with the sample derived from 9h.

It should be noted that the attempted reactions of both 4e and 4h with CH₂N₂ in CHCI₃ did not produce 10e and 10h even in a trace amount and unreacted starting materials were recovered quantitatively. Under similar reaction conditions, neither 8e nor 8h formed 9e or 9h, respectively, and quantitative recoveries of unreacted starting materials were observed in both cases. These facts clearly indicate that the side chain homologation is characteristic to 1-hydroxyindole structure, though the reaction mechanism is sofar unknown. We are now intensely pursuing the structure determination of other two unknown products isolated in the reaction of 6h hoping for obtaining a clue to clarify the reaction mechanism.

Biological evaluations of new 1-hydroxytryptamines and serotonins are in progress.
