Abstract – The stereoselective synthesis of a seco-acid derivative of lepranthin (**1**), a lichen-produced unique 16-membered dimeric macrolide, is described wherein all asymmetric carbon centers were constructed in a highly stereoselective manner, respectively, by using different epoxide-opening reactions of the α,β -unsaturated γ,δ -epoxy ester system and an epoxy alcohol derivative as the key steps.

lepranthin (**1**)

Figure 1

Bacteria, fungi and algae produce a large number of macrolides which are classified as polyketide-derived macrolides in their biosynthetic pathways. These compounds often provided us with good opportunities discovering new drugs. Interestingly, a few macrolides have been isolated from lichens too, which may imply a symbiotic relationship between fungi and algae.¹ Lepranthin (**1**) was isolated from the crustaceous lichen *Arthonia impolita* (Ehrh.) Borrer by Zopf in 1904.² Nearly century later, a NMR

investigation and X-ray analysis by Huneck *et al.* revealed **1** to be a 16-membered homo-macrolide which contains two secondary hydroxyl groups and four secondary acetates.³ Although biological properties and synthetic studies of **1** have not been reported so far, its unique diolide structure would attract attention of synthetic chemists. We report herein the stereoselective synthesis of a seco-acid derivative **28**, the key monomer segment of **1**, based on stereospecific epoxide-ring opening strategies.

Scheme 1. (a) L-(+)-DET, $\text{Ti}(\text{O}^i\text{Pr})_4$, TBHP, CH_2Cl_2 , $-30\text{ }^\circ\text{C}$; (b) Dess-Martin periodinane, CH_2Cl_2 , then $\text{Ph}_3\text{P}=\text{CHCO}_2\text{Me}$; (c) $\text{Pd}_2(\text{dba})_3 \cdot \text{CHCl}_3$, HCO_2H , Et_3N , Ph_3P ; (d) TESCl , imidazole, CH_2Cl_2 ; (e) DIBAH, THF, $0\text{ }^\circ\text{C}$; (f) L-(+)-DET, $\text{Ti}(\text{O}^i\text{Pr})_4$, TBHP, CH_2Cl_2 , $-30\text{ }^\circ\text{C}$; (g) Dess-Martin periodinane, CH_2Cl_2 , then $\text{Ph}_3\text{P}=\text{CHCO}_2\text{Me}$; (h) DDQ, THF, H_2O ; (i) Me_3Al , H_2O , CH_2Cl_2 , $-50\text{ }^\circ\text{C}$; (j) PhCHO , $\text{TsOH} \cdot \text{H}_2\text{O}$, benzene, reflux; (k) DIBAH, THF, $0\text{ }^\circ\text{C}$; (l) L-(+)-DET, $\text{Ti}(\text{O}^i\text{Pr})_4$, TBHP, CH_2Cl_2 , $-30\text{ }^\circ\text{C}$; (m) CuCN , MeLi , Et_2O , -50 to $-30\text{ }^\circ\text{C}$.

Our synthesis started with allyl alcohol **2** which was prepared from commercially available methyl (*R*)-3-hydroxybutylate in five steps.⁴ First, **2** was converted to α,β -unsaturated γ,δ -epoxy ester **4** by a two-step reaction sequence: (1) Katsuki-Sharpless epoxidation⁵ with L-(+)-DET, $\text{Ti}(\text{O}^i\text{Pr})_4$, and TBHP in

CH₂Cl₂ at -30 °C, leading to epoxy alcohol **3**⁶ (87%); (2) Dess-Martin oxidation⁷ followed by Wittig olefination (91% yield). Reductive cleavage of the epoxide **4** with HCO₂H and Pd₂(dba)₃·CHCl₃⁸ smoothly occurred to give alcohol **5** in 85% yield, which was then transformed into allyl alcohol **7** through the sequence of protection of the secondary alcohol with a silyl group and subsequent DIBAH reduction. The allyl alcohol **7** thus obtained was again transformed into α,β-unsaturated γ,δ-epoxy ester **9** by the same reaction sequence as that for **2**: (1) Katsuki-Sharpless epoxidation leading to **8**⁶ (86%); (2) Dess-Martin oxidation; (3) a Wittig olefination (75%, two steps). After removal of the TES group in **9** with DDQ,⁹ treatment of the resulting epoxy alcohol **10** with Me₃Al-H₂O in CH₂Cl₂ at -50 °C afforded the desired product **11** in 70% yield.¹⁰ Protection of *syn*-1,3-diol **11** with a benzylidene acetal group furnished **12**¹¹ in high yield, which was further converted to epoxy alcohol **14**¹² in two steps: (1) reduction with DIBAH in THF (97%); (2) Katsuki-Sharpless epoxidation with L-(+)-DET, Ti(O^{*i*}Pr)₄, and TBHP in CH₂Cl₂ at -30 °C (90%). Upon treatment of **14** with Me₂CuCNLi₂¹³ in Et₂O at -50 to -30 °C, the regioselective methyl substitution reaction smoothly occurred to give **15** as a single product in 89% yield. Thus, the requisite five stereogenic centers in the targeted molecule were stereoselectively constructed by using different epoxide-opening reactions of the two γ,δ-epoxy unsaturated esters, **4** and **10**, and the epoxy alcohol **14**.

The remaining task for the synthesis of a seco-acid was discrimination of the five hydroxyl groups in **15**. To this end, sequential oxidations of **15** with TEMPO¹⁴ and then with NaClO₂¹⁵ followed by esterification with CH₂N₂ produced ester **17** in 67% overall yield. Next, the hydroxyl group in **17** was protected with a MOM group by treatment with MOMCl, DIPEA, and NaI in 1,2-DME, giving rise to **18** in 85% yield. Among discrimination of the five hydroxyl groups, the most difficult task was that between C5 and C7 hydroxyl groups protected by benzylidene acetal. All attempts aiming at a regioselective reductive cleavage of the benzylidene acetal moiety in **18** failed unfortunately. Eventually, distinction between these hydroxyl groups was performed as follows. Removal of the silyl group in **18** with TBAF/AcOH in DMF (90%) followed by treatment of the resulting alcohol with BzCl and pyridine in CH₂Cl₂ furnished **20** (96%), which was converted to diol **21** by catalytic hydrogenolysis with PtO₂ in EtOH. Unexpectedly, the benzene ring in **20** was smoothly hydrogenated concomitantly to produce **21**. Further treatment of **21** with PPTS¹⁶ in refluxing 1,2-dichloroethane in the presence of pyridine resulted in facile lactonization to give lactone **22**, whose hydroxyl group was then protected with ethyl vinyl ether and PPTS¹⁶ in CH₂Cl₂ to afford ethoxyethyl ether **23** quantitatively. Unfortunately, however, subsequent hydrolysis of **23** under alkaline conditions underwent elimination of the MOM group to give unsaturated lactone exclusively. To overcome this difficulty, the lactone **23** was reduced with LiAlH₄ in THF and subsequent regioselective

protection of the primary alcohol with a TBDPS group produced diol **25** (87%). After protection of the diol with acetyl groups (84%), removal of the TBDPS group with TBAF in THF gave the primary alcohol (90%), which was successfully converted to seco-acid **28**¹⁷ for the total synthesis of lepranthin (**1**), in two steps: (1) TEMPO oxidation; (2) sodium chlorite oxidation (82%).

Scheme 2. (a) TEMPO, PhI(OAc)₂, CH₂Cl₂; (b) (1) NaClO₂, NaH₂PO₄ · 2H₂O, 2-methyl-2-butene, THF, ^tBuOH, H₂O, (2) CH₂N₂, Et₂O, 0 °C; (c) MOMCl, DIPEA, NaI, 1,2-DME, reflux; (d) TBAF, AcOH, DMF; (e) BzCl, pyridine, CH₂Cl₂; (f) PtO₂, H₂, EtOH; (g) PPTS, pyridine, (CH₂Cl)₂, reflux; (h) Ethyl vinyl ether, PPTS, CH₂Cl₂; (i) LiAlH₄, THF; (j) TBDPSCl, imidazole, CH₂Cl₂, -25 °C; (k) AcCl, pyridine, CH₂Cl₂; (l) TBAF, THF; (m) (1) TEMPO, TBAB, NaOCl, CH₂Cl₂, NaHCO₃ aq., 0 °C, (2) NaClO₂, 2-methyl-2-butene, NaH₂PO₄ · 2H₂O, THF, H₂O.

In summary, we completed the asymmetric synthesis of the seco-acid **28**, the key monomer of lepranthin (**1**), based on stereospecific epoxide-opening reactions including the stereospecific methylation reaction of the γ,δ -epoxy unsaturated ester **10** with Me₃Al-H₂O system. Further studies of the crucial macrolactonization of the seco-acid **28** toward total synthesis of lepranthin (**1**) are now in progress in our laboratory.
