Association Constants of Lead and Bromide Ions in Molten Sodium Nitrate– Potassium Nitrate Mixtures and their Comparison with the Quasi-Lattice Theory

BY D. L. MANNING,² M. BLANDER, AND J. BRAUNSTEIN

Received September 19, 1962

The association constants K_1 and K_2 for the formation of PbBr⁺ and PbBr₂ were evaluated from electromotive force measurements in molten mixtures of NaNO₃ and KNO₈. The constants K_1 and K_2 in mole fraction units are, respectively, 250, 125 at 240°, 190, 85 at 280°, and 170, 70 at 300° when the solvent is equimolar NaNO₃ and KNO₃. A variation in the composition of the solvent changes the value of the association constants so as to give stronger binding as the proportion of KNO₃ increases. The temperature dependence of the association constants, within the experimental error, is predictable from calculations based on the quasi-lattice model.

Introduction

In this paper, the association constants for the formation of the species $PbBr^+$ and $PbBr_2$ in molten Na-NO₃-KNO₃ mixtures are evaluated from electromotive force measurements. The values are compared with the equations

$$K_1 = Z(\beta_1 - 1)$$
 (1)

$$K_1 K_2 = \frac{Z(Z-1)}{2} (\beta_1 \beta_2 - 2\beta_1 + 1)$$
(2)

which have been derived from the quasi-lattice model,³⁻⁵ where K_1 and K_2 are the association constants for the formation of PbBr⁺ and PbBr₂, respectively, Z is a coördination number, $\beta_i = \exp(-\Delta A_i/RT)$, and ΔA_i is the specific free energy of bond formation. In previous papers,⁶ it was shown that for the association of monovalent ions, ΔA_i is independent of temperature for any given association in any system. Recently, it was demonstrated⁷ that the equations also hold for the association of a divalent ion (cadmium) with Br⁻ and I⁻. Since the quasi-lattice theory applies to monovalent

(7) J. Braunstein and R. M. Lindgren, ibid., 84, 1534 (1962).

ions only, this indicates that calculations based on the model, *i.e.*, eq. 1 and 2, are more general than is implied by the model.

The comparison of experimental measurements with eq. 1 and 2 in this paper was made to further test the applicability of these equations for predicting the temperature coefficient for associations involving a divalent ion. The influence of the solvent cation on the association constants also was measured by varying the composition of the NaNO₈-KNO₈ melt.

Experimental

Reagent grade NaBr was dried at 300° and stored in a desiccator. Reagent grade $Pb(NO_3)_2$ was dried in a vacuum oven at 150° and likewise stored in a desiccator. Otherwise the procedure, apparatus, and methods of calculation were essentially the same as described previously.⁶⁷

Results and Discussion

It was demonstrated⁷ that silver-solid silver halide electrodes are reversible to halide ions in molten nitrates and that the activity coefficient of the alkali halide, $\gamma_{(Na,K)X}$, may be evaluated from e.m.f. measurements of the cell

tions of Pb(NO₃)₂ to the right hand half-cell, values of $1/\gamma_{(Na,K)Br}$ were calculated at several fixed concentrations of alkali bromide. Values of ΔE obtained in 75–25, 50–50, and 25–75 mole % mixtures of NaNO₃ and KNO₃ at different temperatures and at several fixed concentrations of NaBr are given in Table I.

The association constants for the formation of associated lead halide species PbX^+ , PbX_2 , Pb_2X^{3+} , etc., are defined as

$$K_{1} = \frac{R_{PbX}^{+}}{R_{Pb}^{+} + R_{X}^{-}}$$
$$K_{1}K_{2} = \frac{R_{PbX2}}{R_{Pb}^{+} + R^{2}_{X}^{-}}$$
$$K_{1}K_{1,2} = \frac{R_{Pb2X}^{+}}{R^{2}_{Pb}^{+} + R_{X}^{-}}$$

etc., in which the R are mole ratios of the species indicated and in dilute solutions are essentially the same as mole fractions. The stoichiometric activity coefficient of (Na,K)X may be expressed as⁷

$$\frac{1}{\gamma_{(N_{2},K)X}} = 1 + K_{1}R_{Pb(NO_{3})_{2}} + K_{1}K_{1,2}R^{2}_{Pb(NO_{3})_{2}} + (2K_{1}K_{2} - K_{1}^{2})R_{Pb(NO_{3})_{2}}R_{(N_{2},K)X} + \dots$$
(4)

in the range of concentrations in which the associated species follows Henry's law. Plots of $1/\gamma_{(Na,K)X}$ vs. the mole ratio of Pb(NO₃)₂ at low concentrations of alkali halide and of Pb(NO₃)₂ were linear. This indicates that the formation constants of polynuclear

species are comparatively small relative to the first association constant. The first association constants were evaluated graphically as the limiting slopes

$$K_{\rm I} = \lim_{\substack{R_{\rm Pb}(\rm NO_3)_2 \rightarrow 0\\R_{\rm (Ne_{\rm K})_{\rm X} \rightarrow 0}}} \left(\frac{\partial I/\gamma(\rm Ne_{\rm K})_{\rm X}}{\partial R_{\rm Pb}(\rm NO_3)_2}\right)_{R(\rm Ne_{\rm K})_{\rm X}} (5)$$

Large scale plots of $1/\gamma_{(Na,K)X}$ vs. the mole ratio of Pb-(NO₃)₂ were made and the limiting slopes at $R_{Pb(NO_3)_2} =$ 0 were estimated for each fixed stoichiometric mole ratio of (Na,K)X. These slopes then were plotted vs. the mole ratio of alkali halide ($R_{(Na,K)X}$) and extrapolated to $R_{(Na,K)X} = 0$. The intercept is equal to K_1 and from the limiting slope of this plot K_2 may be evaluated from the relationship

$$\lim_{\substack{\text{Rep}(\text{NO}_3)_2 \to 0\\\text{R}_{(\text{Na},\text{K})\text{X}} \to 0}} \left(\frac{\partial^2 1/\gamma_{(\text{Na},\text{K})\text{X}}}{\partial R_{(\text{Na},\text{K})\text{X}} \partial R_{\text{PD}(\text{NO}_3)_2}} \right) = K_1(2K_2 - K_1) \quad (6)$$

Values of K_1 and K_2 calculated from the data in Table I are given in Table II. The estimated errors are about 6% in K_1 and 12% in K_2 .

Table II Association Constants and Derived Parameters for Pb^{++} + Br^- in Molten NaNO₃-KNO₃ Mixtures

Values of ΔA_1 and ΔA_2 were calculated from eq. 1 and 2 for Z = 4, 5, and 6, which should include all reasonable values of Z. For any given solvent and any one value of Z, values of ΔA_1 are constant at all the temperatures investigated. This is further confirmation that the quasi-lattice theory is useful for predicting the temperature coefficient of K_1 for associations involving divalent ions. Within the experimental error, ΔA_2 also appears constant and independent of temperature, and does not differ greatly from ΔA_1 . However, the precision of K_2 was not good enough for a precise evaluation of the temperature coefficient of K_2 .

The solvent influences the value of K_1 so as to lead to stronger binding in molten NaNO₃-KNO₃ mixtures having a higher proportion of KNO₃. This is similar to the influence of the solvent on associations of Ag⁺ and Cd⁺⁺ with halide ions. This solvent effect has been rationalized in terms of coulomb interactions for the association of Ag⁺ with Cl⁻ and Br⁻.^{6f} The picture is not as simple for polyvalent cations such as Pb⁺⁺ and Cd⁺⁺ although one might speculate that the Na⁺ ion, which is smaller than the K⁺ ion, would tend to "polarize" electrons which are involved in binding Pb⁺⁺ and Br⁻ away from the bond, thus weakening the bond.
