S Supporting Information

[AB](#page-11-0)STRACT: [Three synth](#page-11-0)etic analogues of westiallamide, $\rm H_3 L^{wa}$, have previously been synthesized $\rm (H_3 L^{1-3})$ that have a common backbone (derived from L-valine) with H_3L^{wa} but differ in their heterocyclic rings (imidazole, oxazole, thiazole, and oxazoline). Herein we explore in detail through highresolution pulsed electron paramagnetic resonance (EPR) and magnetic circular dichroism (MCD) spectroscopy in conjunction with density functional theory (DFT) the geometric and electronic structures of the mono- and dinuclear Cu^{II}

complexes of these cyclic pseudo hexapeptides. Orientation-selective hyperfine sublevel correlation, electron nuclear double resonance, and three-pulse electron spin echo envelope modulation spectroscopy of $[\mathrm{Cu}^\mathrm{II}(\mathrm{H_2L^1})(\mathrm{MeOH})_2]^+$ reveal delocalization of the unpaired electron spin onto the ligating and distal nitrogens of the coordinated heterocyclic rings and that they are magnetically inequivalent. DFT calculations confirm this and show similar spin densities on the distal heteroatoms in the heterocyclic rings coordinated to the Cu^{II} ion in the other cyclic pseudo hexapeptide $\rm [Cu^{II}(H_2L^{2,3,wa})(MeOH)_2]^+$ complexes. The magnetic inequivalencies in $[Cu^{II}(H_2L^1)(MeOH)_2]^+$ arise from different orientations of the heterocyclic rings coordinated to the Cu^{II} ion, and the delocalization of the unpaired electron onto the distal heteroatoms within these Nmethylimidazole rings depends upon their location with respect to the Cu $^{\rm II}$ d $_{x^2-y^2}$ orbital. A systematic study of DFT functionals and basis sets was undertaken to examine the ability to reproduce the experimentally determined spin Hamiltonian parameters. Inclusion of spin−orbit coupling (SOC) using MAG-ReSpect or ORCA with a BHLYP/IGLO-II Wachters setup with SOC corrections and ~38% Hartree–Fock exchange gave the best predictions of the g and $A^{(63}Cu)$ matrices. DFT calculations of the
¹⁴N hyperfine and quadrupole parameters for the distal nitrogens of the coordinated heterocy $(MeOH)_2$ ⁺ with the B1LYP functional and the SVP basis set were in excellent agreement with the experimental data, though other choices of functional and basis set also provided reasonable values. MCD, EPR, mass spectrometry, and DFT showed that preparation of the dinuclear Cu^{II} complex in a 1:1 MeOH/glycerol mixture (necessary for MCD) resulted in the exchange of the bridging methoxide ligand for glycerol with a corresponding decrease in the magnitude of the exchange coupling.

■ INTRODUCTION

Ascidiacea (ascidians or sea squirts) are sessile filter-feeding marine invertebrate animals that are normally found firmly attached to a substratum such as rocks along coastlines or coral reefs, where the water levels are shallow and the salinity is greater than 2.5%.^{1−6} They have a sac-like body that incorporates three regions, the pharyngeal, abdomen, and postabdomen that is [hou](#page-11-0)sed within a tough outer "tunic" made of the polysaccharide tunicin, which compared to other tunicates leads to a more rigid "exoskeleton". ¹−⁶ The pharyngeal region contains the pharynx, which is the basis of the digestive system involving filtering plankton, m[e](#page-11-0)t[al](#page-11-0) ions, and nutrients out of the seawater through its two siphons. The abdomen contains most of the other bodily organs, and the postabdomen contains the heart and gonads.^{1−6} Ascidians can be found all over the world and are among those marine organisms whose Cu^H accumulation is high[.](#page-11-0)^{7,[8](#page-11-0)} The fact that

 Cu^{II} is found in nonpolar tissue fractions suggests its complexation by low molecular weight organic molecules, such as natural cyclic pseudo peptides, for example, patellamides or proteins. Indeed, the marine genus Lissoclinum is a rich source of cyclic peptide alkaloids, featuring multiple oxazoline, thiazoline, oxazole, or thiazole rings that have interesting cytotoxicity, antibacterial, and antiviral properties.8−¹¹ Ascidians live in a symbiotic relationship with prochloron, a unicellular oxygenic photosynthetic prokaryote bel[ongin](#page-11-0)g to the cyanobacteria phylum, and it is thought that it is responsible for the synthesis of these peptides.^{12−16} The Cu^{II} coordination chemistry of the native cyclic pseudo octa- and hexapeptides purified from L. patella and [L](#page-11-0). [b](#page-11-0)istratum, respectively, and chemically synthesized model cyclic pseudo

Received: June 19, 2014 Published: November 13, 2014

peptides for these two classes has been extensively studied.7,11,17−²⁸ While the biological function of these cyclic pseudo hexa- and octapeptides is at present unknown, the fact tha[t ther](#page-11-0)[e](#page-12-0) is a diverse range of these peptides and that many15,16 are synthesized at the ribosome in an archaic symbiont indicates that they have an important biological role. We [have](#page-11-0) previously shown that dinuclear Cu^H complexes of cyclic pseudo octapeptides can catalyze $CO₂$ fixation (most efficient small molecular weight catalysts known to date) producing carbonate (the backbone of a coral reef), 27 and also mono- and diphosphoester hydrolysis.²⁸ Whether or not the corresponding Cu^{fi} pseudo hexapeptide comple[xes](#page-12-0) have a metabolic role has to our knowledge n[ot](#page-12-0) been reported in the literature.

Westiellamide, a cyclic pseudo hexapeptide $(H_3L^{wa}, Chart 1)$ that has been isolated from the marine genus L. bistratum and

from the terrestrial genus Westiellopsis prolifica, is known to accumulate in leukemia cells and is found to inhibit cytokinesis.²⁹ In solution, the metal-free macrocycle H_3L^{wa} adopts C_3 symmetry (X-ray crystal structures shown in Figure 1), where [th](#page-12-0)e heterocyclic and amide nitrogen atoms point toward the inside of the macrocycle, and the isopropyl residues face to the same side of the macrocycle plane. 3^{0} The fivemembered heterocyclic oxazoline rings result from condensation of threonine side chains with the preced[ing](#page-12-0) carbonyl

groups of the valine residues in the peptide sequence. Three synthetic analogues (Chart 1) of H_3L^{wa} have been prepared (H_3L^{1-3}) that have a common backbone with H_3L^{wa} and differ solely in their heterocyclic donor groups (N-methylimidazole, oxazole, and thiazole).³¹ Plots of their X-ray structures are shown in Figure $1.^{30,31}$ Importantly, the difference in the heterocyclic rings resul[ts](#page-12-0) in subtle differences in the shape of the four macrocycles [as t](#page-12-0)he single (σ) bonds of the oxazoline rings of westiellamide H_3L^{wa} increase the flexibility of the macrocycle.

Initial studies on the metal complexation of westiellamide were performed by Wipf et al., who reported an unusual Ag₄ complex formed with westiellamide.³² In this complex three of the four $Ag⁺$ ions (coordinated to the oxazoline nitrogens) are located in a pseudo trigonal-planar [arra](#page-12-0)ngement about a central Ag⁺ ion, and all four ions are sandwiched between two westiellamide macrocycles. The central Ag⁺ ion is coordinated in a distorted octahedral arrangement by the carbonyl oxygen atoms of the two westiellamide molecules. In addition to the interaction of H_3L^{wa} with Ag^+ , Wipf et al. also observed weak interactions between westiellamide and other metal ions such as Na⁺, Cu⁺, Fe²⁺, Fe³⁺, Hg²⁺, Au²⁺, and Zn²⁺.³²

Investigations of the interaction of Cu^H with $H₃L^{wa}$ and a series of synthetic analogues H_3L^{1-3} (Figu[re](#page-12-0) 1) revealed that after addition of base all cyclic pseudo hexapeptides readily form stable mono- and dinuclear Cu^{II} complexes.²² In the absence of base, Cu^{II} forms a 2:1 (H_3L^2/Cu^{II}) complex in which Cu^{II} is coordinated to the outside of the [mac](#page-12-0)rocycle through the carbonyl oxygen atoms of the peptide bonds, 22 in a similar manner to the central $Ag⁺$ ion in the unusual $[Ag₄ (H_3L^{wa})_2$] complex reported by Wipf et al.³² Pr[ev](#page-12-0)ious investigations of the $Cu^{\bar{II}}$ coordination chemistry of the cyclic pseudo hexapeptides $\mathrm{H_3L^{1-3}}$ and models for the [nat](#page-12-0)ural cyclic pseudo peptide westiellamide H_3L^{wa} revealed interesting differences in their geometric and electronic structures.² While all cyclic pseudo hexapeptides form mononuclear Cu^{II} complexes in the presence of 1 equivalent of base, Cu^H [was](#page-12-0) coordinated to a $\bar{N}_{het}-N_{amide}-N_{het}$ binding site in $\bar{H_3}L^{1-3}$ and to a $N_{\text{het}}-N_{\text{amide}}-N_{\text{het}}-N_{\text{het}}$ binding site in H_3L^{wa} (N_{het} : nitrogen atom of the heterocyclic ring; $N_{\rm amide}$: deprotonated amide nitrogen). The coordination sphere is completed with

Figure 1. X-ray structures^{30,31} of H₃L¹, H₃L², H₃L³, and H₃L^{wa} showing the top (upper) and side (lower) views. Atom colors: nitrogen - blue, oxygen - red, carbon - gray, sulfur−yellow. Hydrogen atoms and solvent molecules were omitted for clarity. Blue, red, and green heterocyclic rings correspond to N-methyli[mida](#page-12-0)zole, oxazole/oxazoline, and thiazole rings, respectively.

aThe ⁶³Cu and ¹⁴N hyperfine values (10⁻⁴ cm⁻¹) were determined from computer simulation of the CW EPR spectra assuming two magnetically equivalent nitrogen $({}^{14}N_{\text{het}})$ nuclei. The nuclear quadrupole interaction was ignored. b For $[Cu^{II}(H_{2}L^{wa})]^{+}$.

one or two axially coordinated solvent molecules. While the binding motif Namide−Nhet−Namide is also possible, the mononuclear Cu^{II} complexes exhibit a strong preference for the $N_{\rm het}-N_{\rm amide}-N_{\rm het}$ binding motif, while in the dinuclear $\rm Cu^{\rm II}$ complexes of H_3L^{1-3} the Cu^{II} ions bind to both binding sites and are bridged by either methanol or methoxide, which helps stabilize the dinuclear complex.²² Cu^{II} complexation requires deprotonation of the amide nitrogen(s), which is metal ion assisted and takes place at relativ[ely](#page-12-0) low pH values. The protons that are released upon coordination of Cu^H acidify the solution, and thus addition of base is mandatory to achieve complete complexation.^{22,23} Since seawater is slightly basic (pH \approx 8), it is likely that metal ions are coordinated to these cyclic pseudo hexapeptides [and](#page-12-0) that these complexes may be involved in metal ion transport or have metabolic roles.

Herein, we extend our previous continuous wave electron paramagnetic resonance (CW EPR) measurements on the mono- and dinuclear Cu^{II} complexes of H_3L^{wa} and the series of synthetic analogues H_3L^{1-3} 22¹ by undertaking high-resolution pulsed EPR and magnetic circular dichroism (MCD) studies in conjunction with density fu[nct](#page-12-0)ional theory (DFT) calculations to further characterize the geometric and electronic structure of the mono- and dinuclear Cu^{II} complexes of H_3L^{1-3} as structural analogues of westiellamide, H_3L^{wa} . A systematic study of the choice of basis set and functional in DFT calculations was also undertaken to determine their suitability for the calculation of the spin Hamiltonian parameters for the $\text{[Cu}^{\text{II}}(\text{H}_{2}\text{L}^{1-3,\text{wa}})$ - $(MeOH)_2$ ⁺ complexes.

EXPERIMENTAL SECTION

Materials. Cyclic peptides $H_3L^{1-3,wa}$ were prepared according to published procedures.^{10,33} All materials obtained commercially were of reagent grade and used without further purification. Triethylamine was obtained from Wak[o](#page-11-0) [Ch](#page-12-0)emicals (Tokyo, Japan). Tetrabutylammonium perchlorate and methanol were purchased from Fluka and Aldrich, respectively.

Methods. X-band (ca. 9.5 GHz) CW and pulsed EPR spectra were recorded with a Bruker Biospin Elexsys E580 EPR spectrometer fitted with either a superhigh Q cavity (CW EPR) or an ER 4118X-MD5 flexline resonator (pulsed EPR). The X-band (∼9.4 GHz) CW EPR spectra were recorded under the following conditions: 140 K, modulation frequency 100 kHz, modulation amplitude 0.05 mT, and microwave power 20 mW (10 dB). The magnetic field and microwave frequency were calibrated with a Bruker ER 036TM Teslameter and a Bruker microwave frequency counter, respectively. An Oxford Instruments flow-through cryostat (CF935LT) in conjunction with an Oxford Instruments ITC503 variable-temperature controller provided temperatures of 1.5−50 K at the sample position in the cavity. Spectrometer tuning, signal averaging, and visualization were accomplished with Bruker's Xepr (version 2.4b.12) software.

Three-pulse electron spin echo envelope modulation (ESEEM) and hyperfine sublevel correlation (HYSCORE)^{34,35} experiments were recorded at 5 K and 9.67 GHz and employed the pulse sequences $\pi/2$ - τ - π/2- t_{[1](#page-12-0)}[-](#page-12-0) π/2 - τ -echo and π/2 - τ - π/2 - t₁ - π - t₂- π/2 - τ -echo, respectively. The following parameters were used: microwave pulse lengths $t_{\pi/2} = 16$ ns, $t_{\pi} = 32$ ns, $\tau = 140$ ns, starting times $t_{1,0} = t_{2,0} =$ 400 ns, and time increments of $\Delta t = 40$ ns. For three-pulse ESEEM experiments 256 points were collected for each trace, and for HYSCORE a 256×256 data matrix was collected. In both three-pulse ESEEM and HYSCORE experiments a four-step phase cycle was used to remove unwanted echoes. All data were processed with MATLAB 2013A (8.1.0.604, The MathWorks, Inc.). The time traces were baseline-corrected with an exponential, apodized with a Gaussian window, and zero filled. After a one-dimensional (three-pulse ESEEM) or two-dimensional (HYSCORE) Fourier transformation, absolutevalue spectra were calculated. X-band Davies electron nuclear double resonance (ENDOR) spectra were recorded at 9.67 GHz at 5 K using the microwave pulse sequence $\pi - T - \pi/2 - \tau - \pi - \tau$ - echo with microwave pulses of lengths $t_{\pi/2} = 24$ ns and $t_{\pi} = 32$ ns, with $\tau = 400$ ns. During time $T = 9 \mu s$ a radio frequency (RF) pulse of 6 μs was applied using 100% gain of a 150 W Applied Engineering RF amplifier.

CW and pulsed EPR spectra of the mono- and dinuclear complexes were simulated with the XSophe-Sophe-XeprView^{36,37} (version 1.1.4), Molecular Sophe^{37,38} (version 2.3.1), and EasySpin³⁹ computer simulation software suites on a personal computer [run](#page-12-0)ning the Mandriva Linux v20[10.2](#page-12-0) operating system. The E[ND](#page-12-0)OR and HYSCORE data were simulated with the program EasySpin³⁹ using the functions salt and saffron. HYSCORE cross-peak positions (frequencies) were matched to the experimental posit[ion](#page-12-0)s by calculating cross-peak frequencies by diagonalization of a spin Hamiltonian (eq 1) with nuclear Zeeman, hyperfine, and nuclear quadrupole interactions (no intensity calculation).

High-resolution electrospray ionization mass spectrometry (ESI-MS) was perfor[med](#page-6-0) with a 9.4 T Bruker ApexQe Qh-ICR hybrid instrument with an Apollo II MTP ion source in the positive-ion electrospray ionization (ESI) mode. Sample solutions in methanol/ glycerol $(1:1)$ at concentrations of $10^{-4} - 10^{-5}$ M were admitted to the ESI interface by means of a syringe pump at 5 mL min[−]¹ and sprayed at 4.5 kV with a desolvation gas flow of 2.0 L min[−]¹ at 25 °C and a nebulizer gas flow of 1.0 L min⁻¹. The ions were accumulated in the storage hexapole for 0.1−1.0 s and then transferred into the ICR cell. Trapping was achieved at a sidekick potential of −4.0 V and trapping potentials of roughly 1 V. The mass spectra were acquired in the broadband mode with 1 M data points. Typically, 16 transients were

accumulated for one magnitude spectrum. The instrument was controlled by Bruker ApexControl 2.0.0.beta software, and data analysis was performed using the Bruker DataAnalysis 3.4 software.

Density functional theory (DFT) calculations were performed with Gaussian $03,^{40}$ Gaussian $09,^{41}$ TURBOMOLE,⁴² ORCA,⁴³ and MAG-ReSpect.⁴⁴ Geometry optimizations were performed using the Respect. Geometry optimizations were related by B3LYP^{45−47} [hy](#page-12-0)brid functio[na](#page-12-0)l in combinatio[n w](#page-12-0)ith the [b](#page-12-0)asis sets 6- $31g^{*47}$ ([C,](#page-12-0) H N, O, S) and TZVP⁴⁸ (Cu). Frequency calculations were perfor[med s](#page-12-0)ubsequent to the geometry optimization to confirm the struc[tur](#page-12-0)es were at a potential [m](#page-12-0)inimum on the potential energy surface. Using these optimized geometries, we examined a wide range of basis sets and functionals to explore the accuracy in reproducing the experimental spin Hamiltonian matrices for the $\lbrack Cu(H₂L^{1,2,3,4})$ $(MeOH)_2$ ⁺ complexes.

Magnetic circular dichroism (MCD) spectra were recorded on an instrument based on a high-throughput/high-resolution Jobin Yvon 750s monochromator and an Oxford Instruments SpectroMag superconducting magnet equipped with an SM4 Cryostat using either a Blue (Hamamatsu R7459) PMT (UV) or Si APD (Vis) detector. The MCD spectra were recorded in a methanol/glycerol 1:1 mixture at various temperatures and magnetic fields.

■ RESULTS AND DISCUSSION

EPR Spectroscopy. CW and pulsed EPR experiments are commonly exploited to gain insights into the Cu^{II} ion geometry, ligating atoms, singly occupied molecular orbital (SOMO), and the extent of delocalization of the unpaired electron spin (i.e., spin density) onto the ligating atoms and atoms within the second coordination sphere.^{22,34,49} X-band CW EPR spectra have already been reported, and the orthorhombic spin Hamiltonian parameters $(g, A^{(63}Cu)$ $(g, A^{(63}Cu)$ $(g, A^{(63}Cu)$ $(g, A^{(63}Cu)$ $(g, A^{(63}Cu)$, $A(^{14}\rm{N}_{\rm{amide}}),\ A(^{14}\rm{N}_{\rm{het}}))$ determined through computer simulation of the first and second derivative EPR spectra are reproduced in Table 1 to allow readers to compare the DFT and EPR results and also the CW EPR and pulsed EPR data presented herein.²²

We extended th[es](#page-2-0)e CW EPR studies by performing orientation-select[ive](#page-12-0) pulsed ENDOR and three-pulse ESEEM and HYSCORE experiments 34 to characterize the hyperfine and nuclear quadrupole couplings to the ligating and distal nitrogen atoms in the N-met[hyl](#page-12-0)imidazole rings of $\rm \left[Cu^{II}(H_2L^1) \right]$ $(MeOH)_2$ ⁺. These techniques provide insights into the extent of delocalization of the unpaired electron onto the heterocyclic rings and peptide backbone. Davies ENDOR spectra (Figure 2c) show signals from strongly coupled $14N$ nuclei with nuclear (ENDOR) frequencies in the range of 15−26 MHz that could be simulated using a model comprised of three nitrogen nuclei, namely, $2 \times N_{\text{het}}$ and $1 \times N_{\text{amide}}^{39}$ These simulations are shown in Figure 2c, and the optimized $14N$ hyperfine and nuclear quadrupole parameters are liste[d i](#page-12-0)n Table 2. The $14N$ hyperfine values determined from the ENDOR data are very similar to the values determined previously from t[he](#page-4-0) X-band CW EPR $data₁²²$ though in this case the nuclear quadrupole interaction was neglected. Utilizing the g and $A(^{63}\mathrm{Cu})$ matrices determined fro[m t](#page-12-0)he CW EPR spectrum and the $A(^{14}N)$ and $P(^{14}N)$ matrices determined from the ENDOR spectra (Table 2) provides for an accurate simulation of the CW EPR spectrum (Figure 2a,b), though the perpendicular region of the spectr[um](#page-4-0) is very sensitive to the choice of g - and A-strain line width parameters.50−⁵² The 14N hyperfine and quadrupole parameters (Table 2) for the ligating nitrogen atoms ($N_{\rm het}$ and $N_{\rm amide}$) are typical of [Cu-](#page-12-0)His (imidazole) complexes^{49,53} and Cu^{II} comple[xe](#page-4-0)s containing coordinated peptide nitrogens.^{53,54} The Davies ENDOR spectrum also reveals ¹H [peak](#page-12-0)s centered around the proton Larmor frequency (Figure 2c, $B_0 = 335$ mT).

Figure 2. CW EPR and Davies ENDOR spectra of $[\mathrm{Cu}^\mathrm{II}(\mathrm{H}_2\mathrm{L}^1)$ - $(MeOH)_2$ ⁺ in methanol. (a) Second derivative X-band CW EPR spectrum (red) and (b) the corresponding simulation optimized to fit the pulsed and CW EPR data (blue). (c) X-band ($\nu = 9.672$ GHz) Davies ENDOR spectra (black) recorded at 5.0 K at the indicated field positions along with the simulations (total blue) for three strongly coupled 14N nuclei (green, red, and magenta). Spin Hamiltonian parameters are given in Table 2. The vertical lines show the ¹H Larmor frequency, and these proton resonances were not simulated.

The ¹ H couplings (∼4 MHz) were not included in the simulated spectra and arise from protons within ca. 3.4 Å (assuming dipole−dipole coupling). These may be assigned to either the backbone CH or equatorially coordinated MeOH ligands $(CH₃$ or OH if not deprotonated) moieties. Without additional ²H exchange data, a unique assignment cannot be made.

Smaller hyperfine couplings to distal nitrogens in the coordinated imidazole rings of $[\mathrm{Cu}^\mathrm{II}(\mathrm{H}_2\mathrm{L}^1)(\mathrm{MeOH})_2]^+$ were characterized with orientation-selective three-pulse ESEEM and HYSCORE experiments. Surface and contour plots of the HYSCORE spectrum (Figure 3a,b) recorded at the echo maximum of the EPR spectrum (near the g_x/g_y positions) allow the assignme[nt](#page-4-0) of ${}^{14}N$ single-quantum (s) and double-quantum (d) cross-peaks and initial guesses for the hyperfine and nuclear quadrupole couplings. Subscripted atom numbers correspond to those from the DFT calculations (see Figure 5). The experimental HYSCORE (Figure 3a,b) and orientationselective three-pulse ESSEM (Figure 3c−black) spectr[a](#page-6-0) clearly show a doubling of the single and do[ub](#page-4-0)le quantum resonances (see N-14a and N-14b, Figure 3b), [in](#page-4-0)dicating 14N hyperfine coupling to two different nitrogen nuclei. In addition the HYSCORE spectra (Figure 3a[,b](#page-4-0)) clearly show cross-peaks (label N-34, Figure 3b) from a weakly coupled ^{14}N nucleus.

^aUnits for A (¹⁴N) and P (¹⁴N) values are MHz, which can be converted to 10^{−4} cm^{−1} by dividing the value by 2.997 92. ^bEasyspin Euler angles (α, β, γ) correspond to a rotation about the "gz" axis, a rotation about the new "gy" axis, and a rotation about the new "gz" axis, respectively. ^CPrincipal values of the nuclear quadupole tensor P are $e^2qQ/h(4I(2I-1))[-(1-\eta)$, $-(1+\eta)$, 2], $I = 1$, $P = e^2qQ/h$, and η varies between 0 and 1.

Figure 3. X-band (ν = 9.671 GHz) HYSCORE (335.0 mT) and orientation-selective three-pulse ESEEM spectra of $\rm [Cu^{II}(H_{2}L^{1})(MeOH)_{2}]^{+}$ in methanol recorded at 5.0 K. (a,b) Surface and contour plots showing the HYSCORE spectrum. (b) A contour plot showing an overlay of the experimental and simulated HYSCORE spectra. ¹⁴N single- and double-quantum cross-peaks are labeled "s" and "d", respectively. A selection of simulated cross-peaks are labeled for three distal ¹⁴N atoms (N-14a (red), N-14b (purple), and N-34 (green)). Atom numbers correspond to those given in Figure 5. For reference the nitrogen Larmor frequency is $v(^{14}N) = 1.03$ MHz. (c) Orientation selective three-pulse ESEEM spectra (black) recorded at the indicated field positions along with the simulations (blue) for the distal nitrogens. Spin Hamiltonian parameters determined from the simulation of b[ot](#page-6-0)h the HYSCORE and three-pulse ESEEM spectra are given in Table 2

Computer simulation of the HYSCORE and orientationselective three-pulse ESEEM spectra (Figure 3), assuming the two peaks labeled N-14a and N-14b (Figure 3b) arise from a single nitrogen atom (N-14) in the N-methylimidazole ring (see Supporting Information, Figure S4), fails to reproduce the double peaks seen in the experimental spectrum. In contrast, com[puter simulation of the HYSCO](#page-11-0)RE and orientationselective three-pulse ESEEM spectra with an anisotropic spin Hamiltonian (eq 1) with three inequivalent $14N$ nuclei (N-14a)

(red), N-14b (purple), and N-34 (green)) and the spin Hamiltonian parameters listed in Table 2 produces simulated spectra (Figure 3b,c) that are in excellent agreement with the experimental spectra. The magnetic inequivalence of the two distal nitrogen nuclei (N-14 and N-34) in the N-methylimidazole rings is also observed in the DFT calculations (see below).⁵⁵ The ¹⁴N hyperfine interactions have an appreciable isotropic component $(A_{iso} (N-14a,b; N-34) = 2.61, 3.00,$ and 1.10 [MH](#page-12-0)z) signifying that a small percentage of the spin

Figure 4. Calculated and experimental (a) g and (b) |A| (⁶³Cu) matrices for $[\mathrm{Cu}^\text{II}(\mathrm{H}_2\mathrm{L}^1)(\text{MeOH})_2]^+$ calculated with various combinations of functionals and basis sets with the programs ORCA⁴³ and MAG-ReSpect.⁴⁴ The experimental values are depicted as horizontal lines.

density is delocalized onto the distal nit[ro](#page-12-0)gens of the coordinated N-methylimidazole rings of the macrocycle. The origin of the two ¹⁴N hyperfine couplings, labeled N-14a and N-14b, will be discussed in conjunction with the DFT studies, below.

Mims and Peisach produced a plot of P versus the asymmetry parameter (η) and showed that the experimental ¹⁴N quadrupole parameters could generally be grouped into three regions, namely, A−deprotonated imidazoles; B−imidazoles coordinated to metal ions; and C-protonated imidazoles.⁵⁶ The $14N$ quadrupole parameters (Table 2) for the distal nitrogen atoms in the coordinated N-methylimidazole ring [in](#page-12-0) $[Cu^{II}(H_2L^1)(MeOH)_2]^+$ fall just outside of [re](#page-4-0)gion B, which is clearly not correct, and this is attributed to N-methylation of the distal imidazole nitrogen reducing the asymmetry of the electric field gradient at the nitrogen nucleus to almost zero (η = 0.09). A similar observation has been made for Cu^{II} diethylenetriamine-substituted imidazole complexes (Im: |P| = 1.43 MHz, $\eta = 0.94$; N-MeIm: $|P| = 2.06$ MHz, $\eta = 0.20$.⁵⁷ This is in contrast to that observed for Cu^{II} centers found in transition metal ion complexes⁵⁷ and metalloproteins,⁵⁸ f[or](#page-12-0) example, phenylalanine hydroxylase⁵⁹ and β -amyloid.^{60,61}

A systematic DFT study of s[qua](#page-12-0)re planar Cu^H diethyl[en](#page-12-0)etriamine imidazole complex[es](#page-12-0) by Ames and Larsen⁵⁵ s[hows](#page-12-0) that the magnitude of the distal $14N$ hyperfine and quadrupole couplings depend on the orientation of the plane of the imidazole ring with respect to the plane of the $d_{x^2-y^2}$ orbital. Maximal and minimal ¹⁴N hyperfine and quadrupole couplings were observed when the ring was perpendicular and parallel to the $d_{x^2-y^2}$ orbital, respectively.⁵⁵ In contrast, the lower symmetry (distorted square pyramidal) of the Cu^{II} center in $\lbrack \operatorname{Cu}^{\text{II}}(H_2L^1) \rbrack$ $(MeOH)_2$ ⁺ and the relative [po](#page-12-0)sition of the distal nitrogens in the coordinated N-methylimidazaole rings (constrained by the cyclic peptide) with respect to the $\tilde{C}u^{II}$ ion yields DFTcalculated $14N$ hyperfine and quadrupole couplings (Tables 2) and 4), which are not in agreement with those of the DFT study of square planar Cu^H diethy[le](#page-4-0)netriamine imidazole com[pl](#page-7-0)exes.⁵⁵ Thus, the precise nature of the SOMO, orientation of the N-methylimidazole rings, and methylation of the dis[tal](#page-12-0) nitrogens will affect the ¹⁴N hyperfine and quadrupole couplings of the ligating and distal nitrogens in the coordinated N-methylimidazole rings.⁵⁶

DFT Calculation of EPR Spin Hamiltonian Parameters. Calculation of spin Hamiltonian para[me](#page-12-0)ters using ab initio or DFT calculations has become quite routine for many transition metal ion complexes and can lead to many insights into their electronic structure.^{62,63} However, a quantitative calculation of the spin Hamiltonian parameters for Cu^H complexes is difficult,

Figure 5. Structures and SOMOs for (a,b) $[\mathrm{Cu}^{\mathrm{II}}(\mathrm{H}_2\mathrm{L}^1)(\mathrm{MeOH})_2]^+$, (c,d) $[Cu^{II}(H_2L^2)(MeOH)_2]^+$, (e,f) $[Cu^{II}(H_2L^3)(MeOH)_2]^+$, and $\rm (gh)$ $\rm [Cu^{II}(H_2L^{wa})(MeOH)_2]^+$ showing delocalization of the unpaired electron onto the N-methylimidazole, thiazole, oxazole, and oxazoline rings of the [18]azacrown-6 macrocyclic rings. Nitrogen atom numbers given in red.

and the resulting values can vary dramatically from the experimentally determined values.⁶⁴ To explore the role of the functional and basis set in the calculation of the g and A matrices for Cu^{II} complexes of H₃L^{1−3} and H₃L^{wa}, we have undertaken a range of DFT calculations utilizing ORCA 2.6⁴³ and MAG-ReSpect 1.2.⁴⁴ These calculations were performed on fully DFT geometry-optimized structures $(G03, ^{40}B3LYP/6 (G03, ^{40}B3LYP/6-$ 31g*) of the respectiv[e c](#page-12-0)omplexes.

The spin Hamiltonian parameters (g and $A^{(63}Cu)$ $A^{(63}Cu)$ $A^{(63}Cu)$ matrices, Table 1)²² of the mononuclear Cu^{II} complexes of H₃L^{1−3} and H₃L^{wa} have been determined previously from computer simula[ti](#page-2-0)[on](#page-12-0) of the CW EPR spectra using the computer simulation software suites XSophe-Sophe-XeprView^{36,37} (version 1.1.4) and Molecular Sophe37,38 (version 2.0.91) in conjunction with the spin Hamiltonian for an isol[ated](#page-12-0) paramagnetic center (H_A) :

$$
H_A = \underline{\mathbf{B}} \bullet g \bullet \underline{\mathbf{S}}^T + \underline{\mathbf{S}} \bullet A(^{63,65}Cu) \bullet \underline{\mathbf{I}}^T
$$

- $g_n \rho_n \underline{\mathbf{B}} \bullet \underline{\mathbf{I}}^T(^{63,65}Cu) + \sum_{i=1}^3 (\underline{\mathbf{S}} \bullet A(^{14,15}N) \bullet \underline{\mathbf{I}}_i^T$
- $g_n \rho_n \underline{\mathbf{B}} \bullet \underline{\mathbf{I}}_i^T(^{14,15}N))$ (1)

The computed g matrices for $[\mathrm{Cu}^\mathrm{II}(\mathrm{H_2L^1})(\mathrm{MeOH})_2]^+$, derived from DFT calculations with various combinations of functionals and basis sets, are listed in Table 3 and are shown

graphically in Figure 4a. Corresponding Tables and Figures for $\left[\text{Cu}^{\text{II}}(\text{H}_{2}\text{L}^{2,3,\text{wa}})\right](\text{MeOH})_{2}\right]^{+}$ are given in the Supporting Information (Tables [S](#page-5-0)1−S3 and Figures S1−S3).

The influence of the amount of exact excha[nge in the](#page-11-0) [functional o](#page-11-0)n the calculated g matrices was probed by using pure GGA functionals, functionals with various amounts of exact exchange (i.e., B3LYP (25% HF) vs B1LYP (20% HF)), and modified BXLYP functionals, where X corresponds to the percentage of exact exchange. The functionals PBE, 65,66 B3PW,^{45,67-69} TPSS,⁷⁰ B3LYP,^{45,46,48} B1LYP,⁷¹ B38LYP, B40LYP, and BHLYP in combination with the basis [sets](#page-12-0) $SVP⁴⁷$ [TZ](#page-12-0)[V,](#page-13-0)⁴⁸ TZV[P,](#page-13-0)⁴⁸ 6-31g^{[*](#page-12-0),[72](#page-12-0)} [6-](#page-12-0)311g^{*,72} [I](#page-13-0)GLO-II,⁷³ IGLO-III,⁷³ EPR-II,⁷⁴ and Wachters⁷⁵ were also used in the calc[ulat](#page-12-0)ions.

There [wa](#page-13-0)s a larg[e v](#page-13-0)ariation in pre[dic](#page-13-0)ted g values among the functionals. The general overestimation of the g shift (especially g_z) has been attributed to a combination of too much covalent bonding and the over prediction of the d-orbital splitting, and consequently hybrid functionals like B3LYP (usually with at least 20% Hartree−Fock exchange) are certainly to be preferred.⁷⁶ However, elevated levels of HF exchange are problematic since they also lead to strong spin contamination.⁷⁷

It was [fou](#page-13-0)nd that increasing the amount of exact exchange to at least 38% is mandatory to obtain g_z values in a reasona[ble](#page-13-0) range (Figure 4a). The best agreement of g_z and g_y with the experimentally derived values is obtained using the B40LYP functional. Alt[ho](#page-5-0)ugh in most of the cases the g matrices are overestimated by the BHLYP functional (50% HF exchange), this was used for further investigations. BHLYP is a wellestablished functional, and its various dependencies are wellunderstood. Manually changing the amount of HF exchange might have some unforeseen influence on the calculation, and thus the application of an established functional was considered reasonable. The MAG-ReSpect calculated g matrices of $[Cu^{II}(H₂ L¹)(MeOH)₂]⁺$ are in best agreement with the experimentally determined values, especially g_z , which is in excellent agreement with the experiment, albeit with a 10-fold increase in computational time.

The EPR-II basis set of Barone is commonly applied in $A^{(63)}$ Cu) matrix calculations.⁷⁴ However, for the investigated Cu^H complexes of H₃L^{1−3} and H₃L^{wa}, it was found that the basis set limit is reached at the IG[LO](#page-13-0)-II level (Figure 4b, Supporting Information, Figures S1−S3, Table 3, and Supporting Information, Tables S1−S3). Utilization of the [I](#page-5-0)G[LO-III and](#page-11-0) [EPR-II basis sets basically provid](#page-11-0)ed identi[ca](#page-7-0)l result[s to those of](#page-11-0) [IGLO-II. Analyzing the data](#page-11-0) (comparison of the experimental and DFT-calculated A_i ($i = x, y, z$) values) it emerges that a basis set without a frozen core region is important as otherwise the A_z values are in good agreement with the experiment, but the $A_{x,y}$ values are greatly overestimated (e.g., TZVP and 6- $31g^*$). Applying the Wachters basis set to Cu^{II} significantly improves the calculation, reproducing the observed trend that $A_{x,y}$ is significantly smaller than A_{z} , yet A_{z} is overestimated by a factor of \sim 2.⁷⁵ This large overestimation is caused by neglecting spin-orbit coupling (SOC) due to Cu^{II}, and the results are substantially [im](#page-13-0)proved when SOC contributions are included. The calculated $A(^{63}Cu)$ matrices for the Cu^{II} complexes of H_3L^{1-3} and H_3L^{wa} and their dependence on the applied basis sets is shown in Table 3 and Supporting Information, Tables S1−S3 and are depicted in Figure 4b and Supporting Information, Figures S1[−](#page-7-0)S3. [The inability to accurately de](#page-11-0)fine [the s-e](#page-11-0)lectron spin density at the nucleus (and hence $A_{iso}(⁶³Cu)$ $A_{iso}(⁶³Cu)$) produces inaccurate $A⁶³Cu)$ matrices [\(Table](#page-11-0) [3\),](#page-11-0)

 a Calculated with program packages MAG-ReSpect 44 and ORCA. 43 The dependence of the g factors on the functional is reflected in the large deviation of the calculated values. The most accurate (sum of squared differences between experiment and calculated) predicted parameters are denoted in bold. b Units, 10^{-4} cm⁻¹. ^cC, H, N, O. d^d [fi](#page-12-0)rst coordina[tio](#page-12-0)n sphere. ^eCu.

Table 4. Experimental and Calculated (ORCA⁴³) $A(^{14}N)$ and $P(^{14}N)$ Values for the Mononuclear Cu^{II} Complex $[Cu^{II}(H₂ L¹)(MeOH)₂]⁺ a$

 a Anisotropic 14 N hyperfine (A) and quadrupole (P) parameters have units of MHz. b Nitrogen atom numbers are given in red in Figure 5. c There are two sets of parameters for N_{distal}-14, potentially arising from two different conformations of the N-methylimidazole ring. ^dThe most accurate (sum of squared differences between experiment and calculated) predicted parameters are denoted in bold.

and consequently results in inaccurate $A(^{14}N)$ hyperfine couplings from ligating nitrogen atoms (Supporting Information, Table S4). However, Lancaster et al. showed that QM/ MM in conjunction with spectroscopy-o[riented con](#page-11-0)figuration [interaction \(SO](#page-11-0)RCI) accurately reproduced the g and ⁶³Cu and ¹⁴N hyperfine matrices for the type zero Cu^{II} center in variants of Pseudomonas aeruginosa azurin.⁶³ In contrast, the $A(^{14}N)$ hyperfine couplings from the distal nitrogen atoms in the Nmethylimidazole rings mainly a[rise](#page-12-0) from a dipole−dipole interaction. This is confirmed in the calculations of the

anisotropic $A(^{14}N)$ hyperfine and $P(^{14}N)$ nuclear quadrupole matrices (Table 4), where there is significantly smaller variation and that all of the results are in reasonable agreement with the experimental values (Tables 2 and 4) obtained from the HYSCORE and three-pulse ESEEM spectra. Spin densities (and the 14N hyperfine cou[pli](#page-4-0)ngs) on the noncoordinated amide and N-methylimidazole nitrogen atoms are significantly smaller at least by a factor of 10 smaller) than those for distal nitrogen atoms of the coordinated N-methylimidazole ligands (Figure 5). Consequently, a plausible explanation for the

observation of two ¹⁴N hyperfine couplings, labeled N-14a and N-14b, is that there are two conformations of the coordinated N-methylimidazole ring. Rotation of the ring must be quite small as the difference between the spin Hamiltonian parameters (N-14a vs N-14b) is quite small (Table 2). Confirmation of this would require ¹⁵N NMR studies of the paramagnetic Cu^{II} complex, followed by molecular modeling [t](#page-4-0)o find the local minima on the potential energy surface and subsequent DFT studies to optimize the geometries and calculate the spin Hamiltonian properties. This is beyond the scope of the current research.

In agreement with the HYSCORE and ESEEM results, the DFT calculations reveal that the distal nitrogens, N-14 and N-34 in the coordinated N-methylimidazole rings are magnetically inequivalent (Table 4), which is reflected in their different spin densities in the singly occupied molecular orbital (SOMO, Figur[e](#page-7-0) 5b). The different ¹⁴N hyperfine couplings result from the N-methylimidazole ring (containing N-34) being twisted out of [th](#page-6-0)e equatorial plane containing the Cu $^{\mathrm{II}}$ d $_{\mathrm{x^2-y^2}}$ orbital and N-34 being oriented between the Cu−ligand bonds (Figure 5a), rather than approximately along the Cu−ligand bond as for N-14. These factors result in reduced isotropic and anisotropic ^{[14](#page-6-0)}N hyperfine couplings for N-34. The DFT calculations (Table 4) also reproduce the experimental quadrupole parameters (P, η) indicating that indeed methylation of the distal nitrogen [re](#page-7-0)duces the asymmetry parameter to approximately zero.

A comparison of the SOMO values for the Cu^{II} complexes $([Cu^{II}(H₂ L¹)(MeOH)₂]⁺, [Cu^{II}(H₂ L²)(MeOH)₂]⁺,$ $\left[\text{Cu}^{\text{II}}(\text{H}_{2}\text{L}^3)(\text{MeOH})_2\right]^+$, and $\left[\text{Cu}^{\text{II}}(\text{H}_{2}\text{L}^{\text{wa}})(\text{MeOH})_2\right]^+\right)$ (Figure 5) reveals subtle differences in the amount of spin density on the distal heteroatoms in the rings (N-methylimidazole, oxa[zo](#page-6-0)le, thiazole, and oxazoline) coordinated to the Cu^{II} ion through the nitrogen atom. For all complexes the distal heteroatoms in the two coordinated heterocyclic rings have inequivalent spin densities $([Cu^{II}(H_2L^1)(MeOH)_2]^+$ - N-14: 3.475×10^{-3} , N-34: -5.37×10^{-4} ; $\left[Cu^{II}(H_2L^2)(MeOH)_2 \right]^+$ -O-14:3.631 × 10⁻³, O-34:1.98 × 10⁻⁴; [Cu^{II}(H₂L³)(MeOH)₂]⁺ $-$ S-14:3.990 \times 10⁻³, S-34:3.83 \times 10⁻⁴; [Cu^{II}(H₂L^{wa}) $(MeOH)_2$ ⁺ - O-14:3.218 × 10⁻³, O-34:4.66 × 10⁻⁴), which originates from the geometric and electronic factors described above for $[\mathrm{Cu}^\mathrm{II}(\mathrm{H}_2\mathrm{L}^1)(\mathrm{MeOH})_2]^+$ (Figure 5a,c,e,g). Interestingly but not unexpectedly, there is more spin density on the distal sulfur atoms (S-14, S-34) of the coord[in](#page-6-0)ated heterocyclic rings as the 3p orbitals are larger than those for N and O (2p orbitals), enabling greater delocalization of the unpaired electron spin. While the spin densities are small, the agreement between the experimental and calculated $14N$ hyperfine and nuclear quadrupole splittings of the distal nitrogen in the heterocyclic rings of $[\mathrm{Cu}^\mathrm{II}(\mathrm{H_2L^1})(\mathrm{MeOH})_2$] $^+$ is excellent giving confidence in the spin densities for the distal atoms in the heterocyclic rings of the other complexes.

MCD Spectroscopy. An MCD experiment provides simultaneous information about the ground and excited states of a paramagnetic material.78,79 A spectrum can be observed when circularly polarized light is propagated through a sample positioned within a stron[g m](#page-13-0)agnetic field parallel to the direction of propagation. The MCD spectrum is detected as the absorbance difference of the substance between left and right circularly polarized light.⁸⁰ The general equation that describes the MCD signal is

$$
\frac{\Delta \varepsilon}{E} = \frac{\varepsilon_{\text{LCP}} - \varepsilon_{\text{RCP}}}{E}
$$

$$
= \gamma \mu_{\text{B}} B \left[\left(-\frac{\partial f(E)}{\partial E} \right) \overline{A}_1 + \left(\overline{B}_0 + \frac{\overline{C}_0}{kT} \right) f(E) \right]
$$
(2)

where γ is a collection of constants, $B =$ magnetic flux density, k = Boltzmann constant, μ_B = Bohr magneton, $f(E)$ = line shape function, T = temperature, ε_{LCP} and ε_{RCP} are the extinction coefficients for left and right circularly polarized light.^{78−82} A_1 , B_{0} , and C_0 are characteristic terms that depend on the electronic and geometric structure of the molecu[le un](#page-13-0)der investigation. Each molecule with degenerate excited states exhibits an A_1 term with a derivative band shape. While the B_0 term has an absorption-like band shape and arises when the applied field causes a mixing of the ground state or an excited state with an intermediate state, the C_0 term is caused by degenerate ground states and is therefore only present in paramagnetic species. It is the only temperature-dependent term, dominating the spectra at low temperatures and identifies paramagnetic species.

Variable-temperature MCD spectra (Figure 6) of $[Cu^{II}(H_2L^1)(MeOH)_2]^+$ reveal a strong temperature depend-

Figure 6. Variable-temperature MCD spectra of $\lbrack \mathop{\rm Cu}^{\text{II}} (\text{H}_2 \text{L}^1)$ - $(MeOH)_2$ ⁺ measured at 5 T in methanol/glycerol (1:1) frozen solution, $c[\mathrm{Cu}^{II}(H_2L^1)(\mathrm{MeOH})_2]^+)$ = 30 mM. (inset) VTVH saturation curves at $\lambda = 700$ nm, experimental (black crosses), and simulated (red lines). All curves are overlaying.

ence of the signals consistent with a large C_0 term arising from the paramagnetic Cu^H center. The MCD saturation curve of the absorption at 700 nm and its fit (red) is shown in the inset to Figure 6. It was fitted assuming $g_z = 2.283$ and an xy polarized transition. This is in agreement with the simulated EPR data (Table 1; $g_z = 2.278$). The MCD spectra of $\text{[Cu}^{\text{II}}(H_2L^1)$ - $(MeOH)_2$ ⁺ are in good agreement with the experimental findings [f](#page-2-0)rom the CW and pulsed EPR, UV−vis, and CD spectroscopic studies, $22,83$ which are characteristic of a square pyramidal Cu^{II} coordination geometry with Cu^{II} bound to the Nhet−Namide−Nhet mo[tif](#page-12-0)[.](#page-13-0)

While the EPR measurements and DFT calculations of the geometry and spin state for the dimer $\left[Cu_2^{\text{II}}(L^1)(\mu\text{-OMe}) \right]$ predict a strongly antiferromagnetically coupled species that is EPR silent at 77 K, the MCD data measured in a methanol/ glycerol (1:1) glass (Figure 7) are consistent with a weakly

Figure 7. Variable-temperature MCD spectra of $\left[\mathrm{Cu}_2^{\text{II}}(\mathrm{L}^1)(\mu-\mathrm{H}^1)\right]$ $OHCH(CH_2OH)_2)]^+$. (a) Experimental spectra measured at 5 T in methanol/glycerol (1:1) frozen solution, $(c(H_3L^1) = 30$ mM). (b) Variable-temperature variable-field curves (black = experimental, red = fit; λ = 660 nm; T = 1.75 K – 50 K, measured at 7 T. Parameters are given in Table 5.

coupled species (nested variable-temperature variable-field (VTVH) curves), and consequently it should be possible to measure an EPR spectrum at 77 K. The possibility that the recorded MCD spectrum arises from an impurity of the monomeric Cu^II complex $[\mathrm{Cu}^\mathrm{II}(\mathrm{H}_2\mathrm{L}^1)(\mathrm{MeO}\mathrm{\tilde{H}})_2]^\mathrm{+}$ in the sample can be excluded for several reasons. The signal that was recorded for the dimeric complex is strong, and the delta absorption values (ΔA) are similar to those of the monomeric species, while a signal arising from an impurity is expected to have considerably smaller Δ absorption values. Furthermore, the peak positions and general appearance of the MCD spectra (Figures 6 and 7a) of the mono- and the dinuclear species are significantly different. The mononuclear complex $[\, \mathrm{Cu}^{\mathrm{II}}(\mathrm{H}_2\mathrm{L}^1)\cdot$ $(MeOH)_2$ ⁺ has a negative Δ absorption band at 700 nm and a positive Δ absorption at 940 nm, whereas the dinuclear Cu^{II} complex of H_3L^1 exhibits two negative Δ absorption bands at 550 and 660 nm. Moreover, the VTVH curves of the dinuclear Cu^{II} complex, measured at 660 nm, are nested, which is a strong indication for coupled species (Figure 7b).

From the experimental VTVH curves of the dinuclear Cu^{II} complex of H_3L^1 , the g matrix, exchange-coupling constant *J*, and the axial (D) and rhombic (E) zero-field splitting values can be derived from a fit of the nested VTVH curves. The VTVH data was analyzed using the formalism developed by

Neese and Solomon, eq 3^{78} For a particular coupled spin system S_1 and S_2 , the MCD magnetization curves are calculated as

$$
\frac{\Delta A}{E} = -\frac{1}{4\pi S} \int_0^{\pi} \int_0^{2\pi} \sum_i N_i (l \langle S_{xli} \rangle M_{yz1}^{\text{eff}} + m \langle S_{yli} \rangle M_{xz1}^{\text{eff}} \n+ n \langle S_{zli} \rangle M_{yx1}^{\text{eff}} + l \langle S_{x2i} \rangle M_{yz2}^{\text{eff}} + m \langle S_{y2i} \rangle M_{xz2}^{\text{eff}} \n+ n \langle S_{z2i} \rangle M_{yz2}^{\text{eff}} \rangle \sin \theta \, d\theta \, d\phi + B_0 B
$$
\n(3)

where N_i are the Boltzmann populations of the energy levels; $\langle S_{x} \rangle$ is the expectation value of the spin operator S_x for spin 1 in level i; l, m, n specifies the direction of the magnetic field with respect to a fixed molecular axis system; and the integration is carried out numerically over all orientations. The $M_{xy}^{\text{eff}}, M_{xz}^{\text{eff}}, M_{yz}^{\text{eff}}$ are the effective transition dipole moment products for transitions centered on either the S_1 or S_2 metal ion. For a transition allowed in x and y polarization, one expects $M_{xy}^{\text{eff}} \gg M_{xz}^{\text{eff}} \approx M_{yz}^{\text{eff}}$. The last term describes the field-dependent B_0 term of eq 2. The population factors N_i and the spin expectation values are calculated from the energies and wave functions, respec[tiv](#page-8-0)ely, of the spin Hamiltonian for the coupled system

$$
H = \sum_{i=1}^{2} H_{Ai} + H_{int}
$$

$$
= -2J_{iso}S_1 \bullet S_2 + S_1 \bullet D \bullet S_2
$$
 (4)

where H_A is given in eq 1. The best fit of the experimental data is shown in Figure 7b. For coupled spin systems the D matrix (quantified by zero-field [sp](#page-6-0)litting D, E values) is nonzero due to a combination of anisotropic exchange (J) and dipole−dipole coupling terms. Without additional structural information about the metal−metal distance and orientation of principal axes, it is difficult to separate these terms. We therefore fitted the dimer VTVH data (Figure 7b) with an effective $S = 1$ spin Hamiltonian resulting in the parameters given in Table 5. The quality of the fit indicates that the Cu^{II} ions are not strongly antiferromagnetically coupled as population of the higher S_{Tot} = 1 spin state would be observed in the VTVH data. Thus, the Cu^{II} ions are either very weakly exchange coupled or strongly

Figure 8. X-Band EPR spectra of $[\mathrm{Cu}_2^{\mathrm{~II}}(\mathrm{L}^1)(\mu\text{-OHCH}(\mathrm{CH}_2\mathrm{OH})_2)]^*$. (a) Experimental EPR spectrum of $[\mathrm{Cu}_2^{\mathrm{~II}}(\mathrm{L}^1)(\mu\text{-OHCH}(\mathrm{CH}_2\mathrm{OH})_2)]^*$ in a methanol/glycerol (1:1) frozen solution, $c(H_3L^1) = 1.5$ mM, $\nu = 9.434$ 401 GHz, T = 50 K. (b) Computer simulation of (a). (c–e) Energy level diagrams showing the allowed EPR transitions along the z , x , and y principal directions, respectively. Spin Hamiltonian parameters are given in Table 5

[fe](#page-9-0)rromagnetically coupled. The only experimental difference between the MCD and EPR-silent experiment of the dimer system as described above, was the presence of 50% glycerol, to generate an optically clear glass. Repeating the EPR measurements under these conditions produced the EPR spectrum shown in Figure 8, which arises from the coupled dinuclear Cu^H complex. When the temperature is decreased to 10 K, saturation of the EPR transitions is observed, which is consistent with a small exchange coupling (Orbach relaxation 84), predicted by the MCD measurements.

The experimental EPR spectrum could be simulated (Figure 8b) [w](#page-13-0)ith an $S = 1$ spin Hamiltonian (eq 4) and the spin Hamiltonian parameters given in Table 5. The corresponding energy level diagrams and [t](#page-9-0)ransitions along the z , x , and y principal directions are shown in Figure [8c](#page-9-0)−e. A mass spectrum of the dinuclear Cu^{II} complex in methanol/glycerol (1:1) reveals peaks (Supporting Information, Figure S5a,c) at $m/z =$ 825.203 58 and 861.054 22. Calculated spectra for $\left[\mathrm{Cu}_2^{\mathrm{II}}(\mathrm{L}^1)\right]$ $(OCH(CH₂OH)₂)MeOH(H₂O)⁺$ (m/z = 861.286 58) and $[Cu₂^{II}(HL¹)(OCH(CH₂OH)₂)MeOH]⁺$ (m/z = 825.26545) (Supporting Information, Figure S5b,d) are in excellent agreement, particularly the isotope distributions (Supporting I[nformation, Figure S5\). Assuming glycer](#page-11-0)ol bridges the two Cu^II ions $(\mathrm{[Cu_2}^\text{II}(\mathrm{L}^1)(\mu\text{-OHCH}(\mathrm{CH_2OH})_2)]^*),$ wh[ich leads to](#page-11-0) [reduced exchange co](#page-11-0)upling, we performed a geometry optimization of the dinuclear complex utilizing DFT methods (B3LYP/6-31g* (C, H, N, O)/TZVP(Cu); Figure 9). This resulted in a calculated exchange coupling constant J_{iso} (−18 cm[−]¹) that was significantly smaller than that for the methoxide-bridged dinuclear complex $(J_{\text{iso}} = -147 \text{ cm}^{-1})$. While the calculation is consistent with the experimental conclusion that the $|J_{\text{iso}}|$ value is small, and confirms that glycerol binding modifies the exchange coupling between the Cu^{II} ions and produces different spectroscopic signatures in both the MCD and EPR spectra, there are a number of uncertainties in the orientation of the bridging glycerol and the possibility of additional solvent molecule(s).

Figure 9. DFT-calculated structure (Gaussian03,⁴⁰ B3LYP/6-31g*/ TZVP) of the glycerol-bridged dinuclear Cu^{II} complex $\lbrack \text{Cu}^{\text{II}}(\text{L}^1)(\mu\text{-}^2) \rbrack$ $OHCH(CH_2OH)_2)$ ⁺. .

■ **CONCLUSIONS**

High-resolution EPR spectroscopy in conjunction with DFT calculations provides a powerful approach for the geometric and electronic structural characterization of paramagnetic species. Herein we utilized orientation-selective pulsed ENDOR, three-pulse ESEEM, and HYSCORE in conjunction with DFT calculations and the published CW EPR data to determine the geometric and electronic structure of $[Cu^{II}(H_2L^1)(MeOH)_2]^+$. The electronic structures of the other $[\mathrm{Cu^{II}}(\mathrm{H}_{2}\mathrm{L}^{2-3,\mathrm{wa}})(\mathrm{MeOH})_{2}]^{+}$ complexes were determined by DFT calculations and utilized the CW EPR data to test the validity of the optimized structure. The geometric structures of $[Cu^{II}(H_2L^{2-3,\bar{w}_a})(MeOH)_2]^+$ were similar to that of $[Cu^{II}(H_2L^1)(MeOH)_2]^+$ except for the Cu^{II} ion coordination sphere in $[\text{Cu}^{\text{II}}(\text{H}_2\text{L}^{\text{wa}})(\text{MeOH})_2]^+$ involved the third oxazoline nitrogen.

Orientation-selective ENDOR measurements of $\rm [Cu^{II}(H_{2}L^{1})(MeOH)_{2}]^{+}$ yielded the ligating nitrogen hyperfine and nuclear quadrupole coupling constants (Table 2), which showed that they were magnetically inequivalent, a consequence of the steric constraints of the ligand and th[e](#page-4-0) differing nitrogens (amide vs imidazole). The $^{14}N_{het}$ and $^{14}N_{amide}$ quadrupole parameters (Table 2) are in agreement with those in the literature for deprotonated imidazole^{58,59} and peptide amide nitrogens.^{54,85} Th[es](#page-4-0)e results are consistent with Cu^H

being coordinated to a $N_{\text{het}}-N_{\text{amide}}-N_{\text{het}}$ binding site in H_3L^1 ,
as suggested from the CW EPR studies²² , as suggested from the CW EPR studies.²

HYSCORE and orientation-selective three-pulse ESEEM measurements on this complex also r[eve](#page-12-0)aled that the distal nitrogens (N-14 and N-34) in the N-methylimidazole rings coordinated to the Cu^{II} ion were also magnetically inequivalent and that there were two populations (conformations, N-14a and N-14b) of the N-methylimidazole ring containing N-14. The relatively large magnetic inequivalence between N-14 and N-34 is a consequence of the N-methylimidazole ring (containing N-34) being twisted out of the equatorial plane containing the Cu^{II} d_{x-y}^2 orbital and being oriented between the Cu−ligand bonds (Figure 5a), rather than approximately along the Cu-ligand as for N-14. These factors result in reduced isotropic and anisotropic $14N$ [h](#page-6-0)yperfine couplings for N-34, which were confirmed with DFT calculations (Table 4). Similar observations were also observed from the spin densities calculated by DFT for the other complexes $(\mathrm{[Cu^{II}(H_{2}L^{2})^{-1})}]$ $(\mathrm{[Cu^{II}(H_{2}L^{2})^{-1})}]$ $(\mathrm{[Cu^{II}(H_{2}L^{2})^{-1})}]$ $(MeOH)_2$ ⁺, $[Cu^H(H₂L³)(MeOH)₂]$ ⁺ and $[Cu^H(H₂L^{wa})$ - $(MeOH)_2$ ⁺). While the spin densities on the N_{het}-N_{amide}- $\rm N_{het}$ binding site within $\rm [Cu^{II}(H_{2}L^{wa})(MeOH)_{2}]^{+}$ were similar to the other complexes, there was additional spin density on the third coordinated oxazoline nitrogen. The experimentally determined η parameters (0.09) for the distal nitrogen atoms (Table 2) are consistent with N-methylation of the imidazole rings.

A sy[ste](#page-4-0)matic study of functionals and basis sets found that the experimental g, $A^{(63)}Cu$ spin Hamiltonian parameters could be reasonably reproduced with MAG-ReSpect⁴⁴ or using $ORCA⁴³$ with the BHLYP functional in combination with the basis sets 6-31g* (C, H, N, S, O), TZVP (first [co](#page-12-0)ordination sphere[\),](#page-12-0) and Wachters (Cu). Importantly, spin−orbit coupling and the incorporation of ∼38% Hartree−Fock exchange were critical for the accurate prediction of the spin Hamiltonian parameters $(g, A^{(63)}Cu)$. Calculation of the distal heterocyclic nitrogen hyperfine and nuclear quadruple couplings were more accurate as the isotropic hyperfine coupling is significantly smaller, and consequently the proportion of Hartree−Fock exchange included in the calculation has only a small effect.

At high base concentrations all macrocycles (H_3L^{1-3}) show the formation of dinuclear methanol (methoxide)-bridged Cu^{II} complexes.²² MCD spectroscopy in conjunction with CW EPR and DFT studies have shown that this bridging ligand is labile and that [it](#page-12-0) can be replaced by glycerol. Upon ligand replacement of the bridging ligand with glycerol, there is a dramatic decrease in the antiferromagnetic exchange coupling between the two Cu^{II} centers. Thus, with an appropriate choice of solvent the dinuclear Cu^{II} complexes of H_3L^{1-3} maybe able to hydrolyze $CO₂$ and phospho mono- and diesters as has been shown for the corresponding dinuclear Cu^{II} complexes of the cyclic pseudo octapeptides.^{27,28} Indeed, preliminary experiments involving the dinuclear Cu^{II} complex with H_3L^1 show that it is capable of [hydr](#page-12-0)olyzing BDNPP (bis(2,4 dinitrophenyl)phosphate). In contrast, the increased flexibility of the oxazoline versus N-methylimidizale, oxazole, and thiazole rings enables H_3L^{wa} to form a mononuclear Cu^{II} center in which the three imidazole and one amide nitrogen atoms are ligated to the Cu^II center, which explains the lack of dinuclear Cu^H complexes in the mass spectra.²² Thus, Cu^H ion transport, homeostasis, and catalysis are possible biological functions for H_3L^{wa} in L. bistratum, where hi[gh](#page-12-0) Cu^{II} concentrations are present.

■ ACKNOWLEDGMENTS

We would like to thank The University of Queensland and the Ruprecht-Karls-Universität Heidelberg for financial support, Dr. B. Martin for critically reading the manuscript, and Miss N. Mehrkens for measuring the mass spectra and performing the preliminary phosphatase hydrolysis experiments. J.H. thanks the Australian Research Council for an award of a Future Fellowship (FT120100421). We would also like to thank the anonymous referee for encouraging us to reexamine the analysis of the HYSCORE and three-pulse ESEEM data.
