Supporting Information

ABSTRACT: New insight into the complexity of the reaction of the prominent catalyst RuCl₂(PPh₃)₃ with carbon disulfide has been obtained from a combination of X-ray diffraction and ³¹P NMR studies. The red-violet compound originally formulated as a cationic π -CS₂ complex, [RuCl(π -CS₂)-(PPh₃)₃]Cl, has been identified as a neutral molecule, RuCl₂(S₂CPPh₃)(PPh₃)₂, which contains the unstable zwitterion S₂CPPh₃. In the absence of RuCl₂(PPh₃)₃, there is no sign of a reaction between triphenylphosphine and carbon disulfide, although more basic trialkylphosphines form red adducts, S₂CPR₃. Despite the presence of an unstable ligand,

 $RuCl_2(S_2CPPh_3)(PPh_3)_2$ is remarkably stable. It survives melting at 173–174 °C intact, is stable to air, and undergoes reversible electrochemical oxidation to form a monocation. When the reaction of $RuCl_2(PPh_3)_3$ with carbon disulfide is conducted in the presence of methanol, crystals of orange $[RuCl(S_2CPPh_3)(CS)(PPh_3)_2]Cl\cdot2MeOH$ and yellow $RuCl_2(CS)(MeOH)(PPh_3)_2$ also form. ³¹P NMR studies indicate that the unsymmetrical dinuclear complex $(SC)(Ph_3P)_2Ru-(\mu-Cl)_3Ru(PPh_3)_2Cl$ is the initial product of the reaction of $RuCl_2(PPh_3)_3$ with carbon disulfide. A path connecting the isolated products is presented.

INTRODUCTION

The reaction of carbon disulfide with transition-metal complexes has been used to prepare a variety of new ligands.^{1,2} Thus, carbon disulfide itself can serve as a ligand, as it does in the π complex, Pt(π -CS₂)(PPh₃)₂,³ but it also serves as a source of the unstable carbon monosulfide ligand. It can also undergo insertion reactions to form dithiocarboxylate and dithiocarbamato ligands. Recent attention on the reactivity of carbon disulfide toward transition-metal complexes has focused on the chemical relationship between carbon dioxide and carbon disulfide and the utility of creating new catalytically active metal complexes for the conversion of carbon dioxide into polymers, fuels, and value-added chemicals.^{4–9}

We became interested in the reactivity of carbon disulfide toward the active hydrogenation catalyst $RuCl_2(PPh_3)_3$ when we began to study the interaction between $RuCl_2(PPh_3)_3$ and fullerenes. $RuCl_2(PPh_3)_3$ crystallizes as a square pyramid with an agostic C–H…Ru interaction that involves one of the triphenylphosphine ligands.¹⁰ In solution, $RuCl_2(PPh_3)_3$ is fluxional and prone to triphenylphosphine loss.^{11,12} We wondered whether $RuCl_2(PPh_3)_3$ might react with C_{60} like several related molecules, e.g., $RhH(CO)(PPh_3)_3$ and IrCl-(CO)(PPh_3)_2, to form stable coordination complexes, which might also have catalytic activity.^{13–15}

Initially, we considered appropriate solvents that would allow us to react $\text{RuCl}_2(\text{PPh}_3)_3$ with C_{60} and other fullerenes. Under an inert atmosphere, $\text{RuCl}_2(\text{PPh}_3)_3$ dissolves in chloroform, acetone, benzene, and ethyl acetate to produce yellow-brown solutions that turn green upon exposure to air.¹⁶ Of these solvents, only benzene is a suitable solvent for fullerenes. We observed that $\text{RuCl}_2(\text{PPh}_3)_3$ dissolved in carbon disulfide, a good solvent for fullerenes,^{17,18} to give a red solution. However, we also became aware that $\text{RuCl}_2(\text{PPh}_3)_3$ was chemically reactive toward carbon disulfide and that there was an extensive and sometimes discombobulating literature on the topic.

Several studies of the reaction between RuCl₂(PPh₃)₃ and carbon disulfide have been documented and a number of ruthenium compounds isolated from that reaction. The structures proposed for these ruthenium complexes are shown in Scheme 1. Wilkinson and co-workers reported that the red solution obtained by boiling a carbon disulfide solution of RuCl₂(PPh₃)₃ under reflux for 5 min produced a red-violet compound (**A**) with the proposed structure [RuCl(π -CS₂)-(PPh₃)₃]Cl in 23% yield along with an orange dimeric complex, Cl(SC)(Ph₃P)₂Ru(μ -Cl)₂Ru(PPh₃)₂(CS)Cl.¹⁹ The yield of the red-violet complex could be increased to 92% when the

Scheme 1. Structures Assigned to the Previously Reported Products Obtained from the Reaction of $RuCl_2(PPh_3)_3$ with Carbon Disulfide

reaction was run in the presence of added triphenylphosphine in a carbon disulfide/methanol mixture. The reaction of $RuCl_2(PPh_3)_3$ with carbon disulfide was reexamined by Stephenson and co-workers, who obtained compound A in only 8% yield.^{20,21} They also obtained the dimer Cl(SC)- $(Ph_3P)_2Ru(\mu-Cl)_2Ru(PPh_3)_2(CS)Cl$ and found a third species, pinkish-red $(SC)(Ph_3P)_2Ru(\mu-Cl)_3Ru(PPh_3)_2Cl$, to be present. That third complex, $(SC)(Ph_3P)_2Ru(\mu-Cl)_3Ru(PPh_3)_2Cl$, was the only compound in Scheme 1 to be characterized by single-crystal X-ray diffraction.²² Its ${}^{31}P{}^{1}H$ NMR spectrum consisted of two AB quartets, in accordance with the structure shown in Scheme 1, where two inequivalent triphenylphosphine ligands are coordinated to two different ruthenium centers.²² Finally, Brothers and Roper obtained trans- $RuCl_2(CS)(H_2O)(PPh_3)_2$ by boiling a mixture of RuCl₂(PPh₃)₃, triphenylphosphine, and carbon disulfide in toluene for 1 week.²³ The authors did not specify the source of the coordinated water molecule.

Here we report our studies of the reaction between $\text{RuCl}_2(\text{PPh}_3)_3$ and carbon disulfide and show that compound **A** is neither a salt nor a π -CS₂ complex.

RESULTS AND DISCUSSION

Preparation and Structure of RuCl₂(S₂CPPh₃)(PPh₃)₂. CS_2 . RuCl₂(PPh₃)₃ dissolves in carbon disulfide to form a red solution. Red-violet crystals precipitate from this solution over a matter of hours. The first crystals to form have been identified as RuCl₂(S₂CPPh₃)(PPh₃)₂·CS₂ through single-crystal X-ray diffraction. Figure 1 shows a drawing of the complex. The two triphenylphosphine ligands are situated trans to one another, while the two chloride ligands are cis. The remaining two coordination positions are occupied by the zwitterionic S2CPPh3 ligand. Some bond distances for this complex are given in Table 1. The RuS₂CP portion involving the zwitterionic S₂CPPh₃ ligand is planar. Thus, the sum of the three angles about carbon is 358.84°. The structure parameters for $RuCl_2(S_2CPPh_3)(PPh_3)_2$ are similar to those of other transition-metal complexes containing zwitterionic S₂CPR₃ ligands.²⁴

While solutions of $\text{RuCl}_2(\text{PPh}_3)_3$ are generally sensitive to air and turn green after exposure to the atmosphere, a solution of $\text{RuCl}_2(\text{PPh}_3)_3$ in carbon disulfide is quite stable in air, and

Figure 1. Molecular structure of red-violet $RuCl_2(S_2CPPh_3)(PPh_3)_2$ · CS_2 drawn with 50% thermal contours. The disordered phenyl group, hydrogen atoms, and solvate CS_2 are omitted for clarity.

crystals of pure $RuCl_2(S_2CPPh_3)(PPh_3)_2 \cdot CS_2$ can be readily prepared without recourse to inert atmosphere methods. However, crystals of $RuCl_2(S_2CPPh_3)(PPh_3)_2 \cdot CS_2$ show an unusual affinity for glass and strongly adhere to the surface of the vessel in which they are prepared. Consequently, we have found it advantageous to prepare crystals of RuCl₂(S₂CPPh₃)- $(PPh_3)_2 \cdot CS_2$ in long glass tubes up to 1 m in length. This technique has allowed us to obtain pure $RuCl_2(S_2CPPh_3)$ - $(PPh_3)_2 \cdot CS_2$ in 20% yield based on RuCl₂ $(PPh_3)_3$. However, if the reaction proceeds as shown in Scheme 2 (vide infra), the yield is 40%. Additionally, samples of $RuCl_2(S_2CPPh_3)(PPh_3)_2$. CS₂ readily lose crystallinity upon drying, apparently because of loss of the solvate molecules. $RuCl_2(S_2CPPh_3)(PPh_3)_2 \cdot CS_2$ is soluble in dichloromethane and is sparingly soluble in carbon disulfide, ether, benzene, toluene, and chloroform. It reacts with the polar solvents methanol and nitromethane. Crystallization of this material from a toluene/carbon disulfide mixture produces crystals of another solvate, $RuCl_2(S_2CPPh_3)(PPh_3)_2$. $0.25CS_2 \cdot 0.25C_7H_8$. This material has also been examined by single-crystal X-ray diffraction. The structure of the ruthenium complex is the same in both solvates. While it was more convenient to conduct the reactions described above in air, we also conducted these reactions under air-free conditions and produced the same products.

The reactions between triphenylphosphine or RuCl₂(PPh₃)₃ and carbon disulfide have been monitored by ³¹P NMR spectroscopy. When carbon disulfide is added to a solution of triphenylphosphine in dichloromethane- d_2 , no shift of the ³¹P resonance is observed either at room temperature or at temperatures as low as -80 °C. This solution is colorless. Thus, we have found no evidence for the formation of the hypothetical adduct S₂CPPh₃, although it has been known for a rather long time that the adduct S₂CPEt₃ can be isolated as a red crystalline solid.^{25,26} It appears that the zwitterionic S₂CPR₃ can only be isolated when the tertiary phosphine is strongly basic.

The ³¹P NMR spectra from the reactions between $RuCl_2(PPh_3)_3$ and carbon disulfide are shown in Figure 2. Trace A shows the spectrum of $RuCl_2(PPh_3)_3$ in a dichloromethane- d_2 solution at 20 °C. At this temperature, $RuCl_2(PPh_3)_3$ is fluxional and produces a broad resonance,

labeled a.^{27,28} As others have noted,^{27,28} triphenylphosphine dissociates from this complex to produce resonance b and some dimeric ruthenium complexes, which are the cause of the other resonances in the 53–37 ppm range. Immediately after the addition of carbon disulfide, the spectrum shown in trace B was produced. The resonances of RuCl₂(PPh₃)₃ and triphenylphosphine have vanished, while a set of new resonances labeled c, which are due to the previously characterized dinuclear complex (SC)(Ph₃P)₂Ru(μ -Cl)₃Ru(PPh₃)₂Cl,²⁹ have appeared

along with the singlet (d), which is due to triphenylphosphine sulfide. The spectrum shown in trace C was obtained 2 h after the addition of carbon disulfide. Two new resonances, labeled e, appeared. These resonances are due to the accumulation of $RuCl_2(S_2CPPh_3)(PPh_3)_2$. Shortly after this time, crystals of $RuCl_2(S_2CPPh_3)(PPh_3)_2$ began to form on the walls of the NMR sample tube. Trace D shows the spectrum obtained by dissolving crystals of $RuCl_2(S_2CPPh_3)(PPh_3)_2 \cdot CS_2$ in dichloro-

Article

Figure 2. ³¹P{¹H} NMR spectra at 20 °C of the reaction between a dichloromethane- d_2 solution of RuCl₂(PPh₃)₃ and carbon disulfide. Trace A shows the spectrum before the addition of carbon disulfide. The peak labeled a arises from RuCl₂(PPh₃)₃, peak b comes from triphenylphosphine, and peak x is due to triphenylphosphine oxide added as a reference. Trace B shows the spectrum after the addition of carbon disulfide. The two AB doublets labeled c are due to (SC)(Ph₃P)₂Ru(μ -Cl)₃Ru(PPh₃)₂Cl, and the singlet d comes from triphenylphosphine sulfide. Trace C shows the same sample after 2 h. The resonances labeled e are due to the formation of RuCl₂(S₂CPPh₃)(PPh₃)₂. Trace D shows the spectrum of crystals of RuCl₂(S₂CPPh₃)(PPh₃)₂·CS₂ dissolved in dichloromethane- d_2 .

methane- d_2 . Two resonances in a 2:1 intensity ratio appear as expected for this complex.

We have also examined the material that precipitates from a carbon disulfide solution containing $RuCl_2(PPh_3)_3$ and triphenylphosphine. Figure 3 shows ${}^{31}P{}^{1}H{}$ NMR spectra of

Figure 3. ³¹P{¹H} NMR spectra at 20 °C dichloromethane- d_2 solutions of the products that precipitate from the reaction of RuCl₂(PPh₃)₃ and triphenylphosphine with carbon disulfide. Traces A–C are acquired from the material that precipitates after 1, 2, and 3 days, respectively. The peaks labeled a arise from RuCl₂(S₂CPPh₃)-(PPh₃)₂ peaks labeled b arise from [RuCl(S₂CPPh₃)(CS)(PPh₃)₂]Cl, while resonances labeled c are presumed to arise from the dimer (SC)Cl(Ph₃P)₂Ru(μ -Cl)₂Ru(PPh₃)₂Cl(CS).

dichloromethane- d_2 solutions of the products that precipitate after 1, 2, and 3 days. Initially, the precipitate is largely RuCl₂(S₂CPPh₃)(PPh₃)₂·CS₂ (resonances labeled a), but over time, the salt [RuCl(S₂CPPh₃)(CS)(PPh₃)₂]Cl (resonances labeled b) is produced as well along with what we presume is the dimer (SC)Cl(Ph₃P)₂Ru(μ -Cl)₂Ru(PPh₃)₂Cl(CS) (resonance labeled c). The reported chemical shift for this complex in chloroform-*d* is 31.3 ppm. We were not able to obtain this material in crystalline form suitable for X-ray diffraction. RuCl₂(S₂CPPh₃)(PPh₃)₂ is a remarkably stable molecule, particularly when one considers the fact that the free ligand, S₂CPPh₃, cannot be detected in solutions of triphenylphosphine in carbon disulfide. No new resonances appeared in the ³¹P NMR spectrum after a solution of RuCl₂(S₂CPPh₃)-(PPh₃)₂·CS₂ in dichloromethane- d_2 had been stored for 3 days. A crystalline sample of RuCl₂(S₂CPPh₃)(PPh₃)₂ melted sharply at 173–174 °C: after cooling and reheating again, it melted sharply at the same temperature. Thus, the complex is quite thermally stable. The cyclic voltammogram shown in Figure 4

Figure 4. Cyclic voltammetry of (A) $\text{RuCl}_2(S_2\text{CPPh}_3)(\text{PPh}_3)_2\cdot\text{CS}_2$ with decamethylferrocene present as an internal standard and (B) $[\text{RuCl}(S_2\text{CPPh}_3)(\text{CS})(\text{PPh}_3)_2]\text{Cl}\cdot2\text{MeOH}$ in a dichloromethane solution with 0.10 M Bu₄NPF₆ as the supporting electrolyte at a glassy carbon electrode. Potentials are referenced to the decamethylferrocene/decamethylferrocinium couple.

reveals that $\text{RuCl}_2(S_2\text{CPPh}_3)(\text{PPh}_3)_2$ undergoes a reversible oxidation to form the cation $[\text{RuCl}_2(S_2\text{CPPh}_3)(\text{PPh}_3)_2]^+$, which we presume is a ruthenium(III) complex. Only irreversible processes were seen upon attempted reduction of $\text{RuCl}_2(S_2\text{CPPh}_3)(\text{PPh}_3)_2$. However, the electrochemistry of the cation $[\text{RuCl}(S_2\text{CPPh}_3)(\text{CS})(\text{PPh}_3)_2]^+$ reveals a reversible reduction, but no oxidation to form the corresponding ruthenium(III) compound. The inability to observe oxidation of $[\text{RuCl}(S_2\text{CPPh}_3)(\text{CS})(\text{PPh}_3)_2]^+$ to the ruthenium(III) state is probably due to the ability of the thiocarbonyl group to stabilize the ruthenium(II) state and the cationic nature of this complex.

Formation of the Cation RuCl(S_2CPPh_3)(CS)(PPh_3)₂]⁺. The cation [RuCl(S_2CPPh_3)(CS)(PPh_3)₂]⁺ was obtained by reacting RuCl₂(PPh₃)₃ with carbon disulfide in the presence of triphenylphosphine and methanol. This was a heterogeneous reaction, with the two solvents forming two layers. After removal of carbon disulfide through evaporation under vacuum, a mixture of four different types of crystals was produced. These crystals were manually separated to yield orange blocks of [RuCl(S_2CPPh_3)(CS)(PPh₃)₂]Cl·2MeOH along with colorless blocks of triphenylphosphine, red-violet needles of RuCl₂(S_2CPPh_3)(PPh₃)₂, and yellow blocks of RuCl₂(CS)-(MeOH)(PPh₃)₂. The identity of each crystal type was determined by single-crystal X-ray diffraction.

The structure of orange $[RuCl(S_2CPPh_3)(CS)(PPh_3)_2]Cl-2MeOH$ is shown in Figure 5. It contains two triphenylphos-

Figure 5. Asymmetric unit of orange $[RuCl(S_2CPPh_3)(CS)(PPh_3)_2]$ -Cl-2MeOH drawn with 50% thermal contours showing hydrogen bonding to the chloride anion. Most hydrogen positions and the disorder in one of the two methanol sites were omitted for clarity.

phine ligands in trans positions, a chelating S_2CPPh_3 ligand, and a chloride and a carbon monosulfide ligand in cis positions. While the RuS₂CP portion of this cation is planar, as it is in RuCl₂(S_2CPPh_3)(PPh₃)₂, the two Ru–S bond distances are decidedly different [Ru1–S1, 2.3234(4) Å; Ru1–S2, 2.5322(5) Å], with the longer Ru–S distance occurring with the sulfur atom that is positioned trans to the carbon monosulfide ligand, which, as expected, exerts a strong structural trans effect.

We found that we could selectively precipitate the orange salt $[RuCl(S_2CPPh_3)(CS)(PPh_3)_2](PF_6)\cdot 1.35CH_2Cl_2$ by treating a dichloromethane solution of the mixture of products from the reaction of RuCl_2(PPh_3)_3 with carbon disulfide and triphenyl-phosphine with ammonium hexafluorophosphate. Orange crystals of $[RuCl(S_2CPPh_3)(CS)(PPh_3)_2](PF_6)\cdot 1.35CH_2Cl_2$ were examined by X-ray diffraction. As seen in the data in Table 1, the cation in this salt has dimensions that are nearly identical with those found in the chloride salt, $[RuCl(S_2CPPh_3)_2]Cl\cdot 2MeOH.$

The ³¹P{¹H} NMR spectrum of [RuCl(S₂CPPh₃)(CS)-(PPh₃)₂]Cl-2MeOH in a dichloromethane- d_2 solution shows two resonances: a triplet ($J_{P,P} = 4$ Hz) at 16.4 ppm due to the S₂CPPh₃ ligand and a doublet ($J_{P,P} = 4$ Hz) at 30.15 ppm assigned to the two equivalent triphenylphosphine ligands with an intensity ratio of 1:2. A dichloromethane- d_2 solution of

 $[RuCl(S_2CPPh_3)(CS)(PPh_3)_2](PF_6)\cdot 1.35CH_2Cl_2$ produces a similar spectrum but has added resonances from the anion.

The absorption spectra obtained from $[RuCl(S_2CPPh_3)-(CS)(PPh_3)_2]Cl·2MeOH$ and $RuCl_2(S_2CPPh_3)(PPh_3)_2·CS_2$ are shown in Figure 6. For the most part, these spectra are

Figure 6. Top: Photographs of a red-violet needle of $RuCl_2(S_2CPPh_3)(PPh_3)_2$ (upper) and an orange block of $[RuCl-(S_2CPPh_3)(CS)(PPh_3)_2]Cl\cdot2MeOH$ (lower). Bottom: UV/vis absorption spectra of $RuCl_2(S_2CPPh_3)(PPh_3)_2$ and $[RuCl(S_2CPPh_3)(CS)-(PPh_3)_2]Cl$ in a dichloromethane solution.

similar. However, the spectrum of $RuCl_2(S_2CPPh_3)(PPh_3)_2$ shows low-energy features at 805 nm with a shoulder at 1050 nm, but similar features are absent from the spectrum of the cation. These visible absorptions are likely associated with the RuS_2C unit because the related free ligand S_2CPEt_3 is itself red. Crystals of $[RuCl(S_2CPPh_3)(CS)(PPh_3)_2]Cl·2MeOH$ and $RuCl_2(S_2CPPh_3)(PPh_3)_2 \cdot CS_2$ are not luminescent at room temperature or at 77 K.

Preparation and Identification of RuCl₂(CS)(MeOH)-(**PPh₃)₂.** Yellow blocks of RuCl₂(CS)(MeOH)(PPh₃)₂ formed in small amounts in the reaction of RuCl₂(PPh₃)₃ with carbon disulfide, triphenylphosphine, and methanol. Additionally, we have found that RuCl₂(CS)(MeOH)(PPh₃)₂ is formed, along with triphenylphosphine sulfide, by sonication of a sample of RuCl₂(S₂CPPh₃)(PPh₃)₂ in methanol. The ³¹P{¹H} NMR spectrum of the isolated complex in a dichloromethane-*d*₂ solution shows a simple singlet at 31.1 ppm. The IR spectrum shows a characteristic ν (CS) at 1280 cm⁻¹. The crystallographically obtained structure of the complex is shown in Figure 7. The complex is six-coordinate with trans triphenyl-

Figure 7. Structure of yellow $RuCl_2(CS)(MeOH)(PPh_3)_2$ drawn with 50% thermal contours.

phosphine ligands, cis chloride ligands, a carbon monosulfide ligand, and a coordinated methanol ligand. While this appears to be a rather ordinary six-coordinate ruthenium(II) complex, the Cl1–Ru–Cl2 angle [163.908(19)°] is somewhat bent so that both chloride ions are drawn toward the methanol ligand. The mode of preparation of this complex suggests that the carbon monosulfide ligand is obtained from the S₂CPPh₃ ligand in its precursor, [RuCl(S₂CPPh₃)(CS)(PPh₃)₂]⁺. RuCl₂(CS)-(MeOH)(PPh₃)₂ has been obtained previously through another route.²¹ Note that RuCl₂(CS)(MeOH)(PPh₃)₂ is similar to the product RuCl₂(CS)(OH₂)(PPh₃)₂ that Brothers and Roper produced from RuCl₂(PPh₃)₃ via a rather lengthy reaction.²³

The reaction between RuCl₂(PPh₃)₃ and carbon disulfide is complex, with several different compounds emerging at different time intervals. Scheme 2 summarizes the products that have been obtained from the reactions of RuCl₂(PPh₃)₃ and carbon disulfide and shows the reaction paths that connect them. All compounds shown have been identified by ³¹P NMR spectroscopy and by single-crystal X-ray diffraction with the exception of $Cl(SC)(Ph_3P)_2Ru(\mu-Cl)_2Ru(PPh_3)_2(CS)Cl$, whose crystal structure has not been obtained despite our efforts and those of others. The initial formation of the unsymmetrical dinuclear complex $(SC)(Ph_3P)_2Ru(\mu-Cl)_3Ru$ - $(PPh_3)_2Cl$, as demonstrated by the data in Figure 2, contributes to the complexity of the situation because two different ruthenium coordination environments are produced by its creation. Fragmentation of this dimer can yield the hypothetical fragments "(SC)(Ph₃P)₂RuCl₂" and "Ru(PPh₃)₂Cl₂". The latter can react with carbon disulfide and triphenylphosphine to form $\operatorname{RuCl}_2(S_2\operatorname{CPPh}_3)(\operatorname{PPh}_3)_2$, which initially precipitates from solution. As shown in Scheme 2, the "(SC)(Ph_3P)_2RuCl₂" fragment can dimerize to form $\operatorname{Cl}(\operatorname{SC})(\operatorname{Ph}_3P)_2\operatorname{Ru}(\mu-\operatorname{Cl})_2\operatorname{Ru}(\operatorname{PPh}_3)_2(\operatorname{CS})\operatorname{Cl}$, which can subsequently react with carbon disulfide and triphenylphosphine to form [RuCl(S_2CPPh_3)-(CS)(PPh_3)_2]Cl. The ruthenium complexes shown in Scheme 2 all involve ruthenium(II). The formation of triphenylphosphine sulfide is always accompanied by the formation of a coordinated CS ligand according to the reaction:

 $CS_2 + PPh_3 \rightarrow CS (as a ligand) + SPPh_3$

The red-violet compound (A), which had been proposed to be the π -carbon disulfide adduct [RuCl(π -CS₂)(PPh₃)₃]Cl, has now been correctly identified as $RuCl_2(S_2CPPh_3)(PPh_3)_2$, a remarkably stable complex that contains the otherwise unstable zwitterionic S₂CPPh₃ ligand. Note that the melting point reported for A (173-174 °C) is identical with that obtained by us for $RuCl_2(S_2CPPh_3)(PPh_3)_2$. The misidentification of A as a salt may have resulted from coprecipitation of [RuCl- $(S_2CPPh_3)(CS)(PPh_3)_2$ Cl with RuCl₂ $(S_2CPPh_3)(PPh_3)_2$ because both are formed in the reaction of $RuCl_2(PPh_3)_3$ with carbon disulfide. Additionally, both have similar colors, as shown in Figure 6, and similar melting points. Previous workers have not recognized the presence of $[RuCl(S_2CPPh_3)(CS) (PPh_3)_2$ Cl in the RuCl₂ $(PPh_3)_3$ /carbon disulfide reaction. Although there are several studies of coordination complexes of the zwitterionic S₂CPR₃ ligands, where the R substituents are aliphatic groups and the free ligand can itself be isolated,² there are few reports of complexes containing the unstable S₂CPPh₃ ligand and no reports of the chemical behavior of these compounds. Thus, the reaction of carbon disulfide with $IrCl(CO)(PPh_3)_2$ and triphenylphosphine has been shown by X-ray diffraction studies to produce the cation $[Ir(S_2CPPh_3) (CO)(PPh_3)_2]^+$, which was originally formulated as the π -CS₂ complex $[Ir(\pi$ -CS₂)(CO)(PPh₃)₂]^{+.30,31} By analogy, Clark et al. suggested that $[RuCl(\pi-CS_2)(PPh_3)_3]Cl$ might be better formulated as RuCl₂(S₂CPPh₃)(PPh₃)₂, but they did not investigate the matter any further. The reaction of the radical cation $[Fe(CO)_3(PPh_3)_2](PF_6)$ with carbon disulfide was reported to yield a mixture of $[Fe(S_2CPPh_3)(CO)_2(PPh_3)_2]$ -(PF₆)₂ and $Fe(CO)_3(PPh_3)_2$.^{32,33} [Fe(S₂CPPh₃)- $(CO)_2(PPh_3)_2](PF_6)_2$ was not characterized crystallographically.

EXPERIMENTAL SECTION

Materials. $\operatorname{RuCl}_2(\operatorname{PPh}_3)_3$ was prepared according to a reported method.¹⁶ Carbon disulfide, triphenylphosphine, and methanol were purchased commercially and used as received.

RuCl₂(S₂CPPh₃)(PPh₃)₂·CS₂. A sample of RuCl₂(PPh₃)₃ (199 mg, 0.21 mmol) was dissolved in 8 mL of CS₂, forming a dark-red solution within 2 min. This solution was filtered into a 5-mm-diameter open glass tube, approximately 1 m in length, and capped with a rubber septum. Red-violet needles formed within 1 h. The red-violet needles were collected after 24 h (yield: 43 mg, 20%). Mp: 173–174 °C. ³¹P{¹H} NMR (dichloromethane-*d*₂ at 298 K): δ 24.26 (s), 1.03 (s). FTIR (cm⁻¹): 3050, 2924, 2855, 1584, 1519, 1479, 1432, 1184, 1102, 1090, 1070, 1028, 988, 951, 739, 716, 684, 563, 508. UV/vis [dichloromethane; λ_{max}, nm (ε, M⁻¹ cm⁻¹)]: 348 (2100), 510 (2400), 805 (95).

Reaction of $RuCl_2(PPh_3)_3$ and Triphenylphosphine in Methanol/Carbon Disulfide. A sample of 310 mg (0.33 mmol) of $RuCl_2(PPh_3)_3$ and 510 g (1.9 mmol) of triphenylphosphine was placed in a 100 mL flask equipped with a stir bar. This flask was vacuum-

^{*a*}For data with $I > 2\sigma(I)$, R1 = $\sum_{i=1}^{n} (||F_o| - |F_c||) / \sum_{i=1}^{n} |F_o|$. ^{*b*}For all data, wR2 = $\{\sum_{i=1}^{n} [w(F_o - F_c)^2] / \sum_{i=1}^{n} [w(F_o^2)^2] \}^{1/2}$.

pumped and nitrogen-backfilled five times. In a separate flask, carbon disulfide (10 mL) and methanol (10 mL) were purged with nitrogen for 15 min. During the purge, methanol and carbon disulfide formed two layers, which were mixed using a stir bar. This solvent mixture was transferred by a cannula into the primary flask, forming a red-violet two-phase solution. The mixture was evaporated under vacuum, with

preferential loss of carbon disulfide. By the time most of the carbon disulfide was removed, crystals formed. The crystals were extracted and examined microscopically. The precipitate was determined to contain four different types of crystals: colorless blocks of PPh₃, orange blocks of $[RuCl(S_2CPPh_3)(CS)(PPh_3)_2]Cl-2MeOH$, red-violet needles of $RuCl_2(S_2CPPh_3)(PPh_3)_2$, and yellow blocks of $RuCl_2(CS)-(MeOH)(PPh_3)_2$. These crystals were manually separated to produce separate samples of each compound.

[RuCl(S₂CPPh₃)(CS)(PPh₃)₂]Cl·2MeOH. RuCl₂(PPh₃)₃ (203 mg, 0.21 mmol) and PPh₃ (116 mg, 0.44 mmol) were dissolved in 8 mL of carbon disulfide to form a deep-red solution. A 0.5 mL portion of methanol was added, and the mixture turned violet. This mixture was filtered into four 5-mm-diameter open tubes of ca. 20 cm length. The resulting tubes then showed two distinct layers: the lower layer was a deep-red solution (CS₂), and the top layer was black and viscous. The tubes were inverted several times to allow mixing and were allowed to stand for 1 week. Orange blocks up to 5 mm on a side formed, and these crystals were collected from all four tubes (yield: 88 mg, 39%). Mp: 175 °C. ³¹P{¹H} NMR (CD₂Cl₂ at 298 K): δ 30.15 (d, $J_{P,P} = 4$ Hz), 16.45 (t, $J_{P,P} = 4$ Hz) with integration 2:1. FTIR (cm⁻¹): 3181 (ν_{OH}), 3047, 1617, 1581, 1479, 1433, 1263 (ν_{CS}), 1186, 1163, 1108, 1088, 1025, 995, 971, 849, 747, 727, 693, 558, 511.

[**RuCl(S₂CPPh₃)(CS)(PPh₃)₂](PF₆)·1.35CH₂Cl₂.** A mixture of RuCl₂(S₂CPPh₃)(PPh₃)₂, [RuCl(S₂CPPh₃)(CS)(PPh₃)₂]Cl, and RuCl₂(CS)(MeOH)(PPh₃)₂ (11.5 mg) prepared as described above was dissolved in 2 mL of dichloromethane to form a dark-red solution. Ammonium hexafluorophosphate (25 mg, 150 µmol) was dissolved in 4 mL of methanol, and the resulting solution was added to the dichloromethane solution. Red-orange blocks suitable for X-ray diffraction formed from the resulting dark-red solution within 1 day (yield: 1 mg). ³¹P{¹H} NMR (CD₂Cl₂ at 298 K): δ 30.23 (d, *J*_{P,P} = 4 Hz), 16.42 (t, *J*_{P,P} = 4 Hz) [phosphorus from (PF₆)⁻ at -144.9 with *J*_{P,F} = 710 Hz]. FTIR (cm⁻¹): 3320 (ν_{OH}), 3050, 1586, 1480, 1433, 1271 (ν_{CS}), 1186, 1108, 1092, 1028, 998, 971, 823, 742, 692, 623, 611, 556, 513, 503. UV/vis [dichloromethane; λ_{max}, nm (ε, M⁻¹ cm⁻¹)]: 427 (1400), 527 (1100).

RuCl₂(CS)(MeOH)(PPh₃)₂. Crystals suitable for X-ray diffraction were obtained by dissolving RuCl₂(S₂CPPh₃)(PPh₃)₂·CS₂ in methanol under air or anaerobic conditions and allowing the purple solution to stand. Yellow blocks formed amidst a purple solution. Alternatively, sonication of RuCl₂(S₂CPPh₃)(PPh₃)₂ (35 mg, 34 μ mol) in methanol (20 mL) resulted in the formation of 6 mg (23%) of a yellow precipitate of RuCl₂(CS)(MeOH)(PPh₃)₂ within a murky purple solution. Mp: 182–184 °C. ³¹P{¹H} NMR (CD₂Cl₂ at 298 K): δ 31.1 (s). FTIR (cm⁻¹): 3560 (ν _{OH}), 3051, 2950, 1574, 1509, 1479, 1433, 1280 (ν _{CS}), 1183, 1158, 1088, 1028, 995, 846, 740, 687, 513, 501.

Physical Measurements. IR spectra were recorded on a Bruker Alpha FTIR spectrometer. NMR data were collected on a Bruker Avance DRX 500 MHz spectrometer. UV/vis absorption spectra were collected on a Shimadzu UV-3600 spectrophotometer. All cyclic voltammograms were collected under an inert dinitrogen (Praxair, 99.999%) atmosphere in a dichloromethane solution with a 0.10 M (n-Bu₄N)(PF₆) supporting electrolyte that had been stored on 3 Å molecular sieves for a minimum of 48 h before use. Scans were performed using a glassy carbon working electrode, a silver wire pseudo reference electrode, and a platinum wire counter electrode. The silver wire pseudo reference (Fc*) standard. Under these experimental conditions, the Fc*^{0/+1} couple has $E^{0'} = -0.59$ V versus Fc^{0/1+}.

Single-Crystal X-ray Crystallography and Data Collection. Crystals of $\text{RuCl}_2(S_2\text{CPPh}_3)(\text{PPh}_3)_2$ (red-violet needles) and $\text{RuCl}_2(\text{CS})(\text{MeOH})(\text{PPh}_3)_2$ (yellow blocks) were mounted in the 100 K nitrogen cold stream provided by an Oxford Cryostream low-temperature apparatus on the goniometer head of a Bruker D8 diffractometer equipped with a Photon 100 CMOS detector. Data were collected with the use of synchrotron radiation ($\lambda = 0.77490$ Å) at Beamline 11.3.1 at the Advanced Light Source, Lawrence Berkeley Laboratory. Crystals of [RuCl(S_2CPPh_3)(CS)(PPh_3)_2]Cl-2MeOH (orange blocks) and [RuCl(S_2CPPh_3)(CS)(PPh_3)_2](PF_6)-1.35CH_2Cl_2 (orange blocks) were selected for data collection on a Bruker D8 DUO diffractometer employing Mo K α radiation ($\lambda = 0.71073$ Å) and a Cryo Industries low-temperature apparatus. All data sets were reduced with the use of Bruker *SAINT*,³⁴ and a multiscan absorption correction was applied with the use of *SADABS*.³⁴ Structure solution and refinement were conducted with *SHELXS-2008*³⁵ and *SHELXL-2014*,³⁶ respectively. Crystallographic data are reported in Table 2.
