$(EDTA)^{2-}$ and $H(NTA)^{2-}$ and also between VO_2EDDA^- and $H(NTA)^{2-}$ and between VO₂EDDA⁻ and H_2NTA^- .

There exist several paths of reaction via the formation of outer-sphere complexes between the reacting chelates and the entering aminocarboxylate ligands. These reactions are followed by ligand interchanges, which are the limiting steps of the reactions. For example, we propose, in Figure **3,** a scheme for the ligand-exchange reaction between $VO₂EDTA³⁻$ and $H(NTA)^{2-}$. The first step is a fast formation of an outersphere preequilibrium complex. The structure of the $VO₂EDTA³$ complex, with no water bonded to the vanadium and no very weak vanadium-ligand bond, and the lack of significant variation of the spectrum between 220 and 400 nm during this first step lead **us** to postulate the formation of this outer-sphere complex. The following steps might be reactions of interchange between one chelating group of EDTA bonded to the metal and one entering chelating group of NTA. The cleavage of a metal-EDTA nitrogen bond must be the key process. All these interchange reactions between chelating groups of the leaving ligand and chelating groups of the entering ligand are apparently first order as the reactions occur in outer-sphere complexes and do not involve direct attack of external species. Thus the rate constants of the ligand-interchange reactions must be of the same order of magnitude $(0.1-0.6 \text{ s}^{-1})$ as we have experimentally shown. This is due to the fact that in all reactions, the broken and new bonds are almost the same.

In conclusion, the results presented above show that the mechanism of chelating group exchange reactions depends on whether the central metal is or is not bonded to water molecules.

Registry No. VO₂EDTA³⁻, 68907-94-8; VO₂EDDA⁻, 38868-05-2; H,NTA, 139-13-9.

4: 1 Lewis Base Adducts of Palladium Bis(hexafluoroacetylacetonate). The Structure of $(4-CIC_sH₄N)₄Pd(C_sHF_sO₂)$

A. **R.** SIEDLE*la and L. H. PIGNOLETlb

Received *May 19, 1981*

Palladium bis(hexafluoroacetylacetonate), Pd(F₆acac)₂, reacts with a wide variety of Lewis bases to form 4:1 adducts of the type $(L_4Pd_2)(F_6acac)$ ₂ where L includes (CH₃)₂NH, CH₃NH₂, NH₃, C₅H₃N, imidazole, 3,5-(CH₃)₂-pyrazole, t-C₄H₉NC, Ph₃Sb, benzothiazole, and 1,3-dithiolene-2-thione and the chelating bidentate ligands $Ph_2PC_2H_4PPh_2$, $Ph_2PCH_2PPh_2$, $Ph_2AsC_2H_4AsPh_2$, and 1,4-C₄H₈S₂. Metathesis with NH₄PF₆ yields $(L_4Pd)(PF_6)_2$. These compounds were characterized by conductivity and spectroscopic measurements. The 4-chloropyridine adduct $(4-CIC_5H_4N)_4Pd(F_6acac)$, was characterized by single-crystal X-ray diffraction. Crystal data: space group $P2_1/c$, $a = 19.356$ (3) \AA , $b = 18.902$ (3) \AA , $c = 10.636$ (2) \AA , β = 100.12°, \dot{V} = 3831 \AA ³. There are two crystallographically independent molecules per unit cell. Both F₆acac groups have been displaced, and the pyridine rings in the $(4-CIC_5H_4N)_4Pd$ group are mutually perpendicular and $d(Pd-N)_{av}$ in the planar PdN₄ unit is 2.029 Å. Two oxygens, one from each F_6 acac, occupy axial positions with $d(Pd-O) = 3.02$ **A.**

Introduction

The chemistry of palladium **bis(hexafluoroacetylacetonate),** $Pd(F_6, acac)_2$, is extensive in scope. It is a strong Lewis acid and with molecular bases forms adducts of the general formula $Pd(F_6,acac)_2$ (ligand), where $n = 1, 2, 3$, or 4. Previous papers from these laboratories have characterized the $n = 1$ and 2 classes of adducts² and their role in ortho metalation³ and β -diketonate transfer reactions⁴ as well as acid-base surface complexes formed with use of metal oxides as condensed-phase donors.^{5,6} This paper describes the synthesis and properties of the $n = 4$ class, Pd(F₆acac)₂(ligand)₄, and reports the crystal structure of a representative member, $Pd(F_6acac)$, (4- $ClC_5H_4N)_4.7$

Synthesis and Properties of 4:l Adducts

Addition of Lewis bases to solutions of $Pd(F_6acac)_2$ in solvents of low dielectric constant such as chloroform, toluene, or pentane results in successive displacement of the F_6 acac groups⁸ to yield $Pd(F_6acac)_2(base)$ $(n = 1, 2, 3, 4)$. The stoichiometry of the materials isolated appears to be a function of the steric and electronic properties of the donor molecule. When the base is a strong σ donor and not highly hindered, these reactions go to completion to yield only $Pd(F_6acac)_2$ -(ligand),. Examples of such bases include ammonia and methylamine. The 4:l adducts usually have low solubility in nonpolar solvents and separate from the reaction mixtures in analytical purity. Dimethylamine is a more hindered donor and generates both 1:l and 2:l adducts when a deficiency of amine is employed but, in the presence of excess amine, provides Pd(F₆acac)₂[(CH₃)₂NH]₄ (1). Heterocyclic nitrogencontaining donors such as pyridine, imidazole, and 3,5-dimethylpyrazole all afford 4:1 adducts in nearly quantitative yield. Analytical and spectroscopic data for these and other new compounds prepared are given in Tables S1-4 (supplementary material).

As confirmed by the X-ray structure of the tetrakis(4 chloropyridine) adduct described below, the 4:1 Lewis base complexes have the general formula $(L_4Pd^{2+})(F_6acac^-)_2$. Tight ion pairing appears to occur in solution so that, for example, the osmometric molecular weight in chloroform of $(py)_4Pd$ - $(F_6, acac)_2$ (3) is 710 while the value calculated for an undissociated compound is 836. However, a plot of $\Lambda - \Lambda_e$ vs. $c^{1/2}$ for 3 over a concentration range of $10^{-3}-10^{-5}$ M in nitromethane was linear and had a slope of 428, which is consistent with the behavior of a 2:1 electrolyte. 9 The ionic nature of the pyridine complex in solution was confirmed by its reaction with ammonium hexafluorophosphate in methanol to produce $[(py)_4Pd](PF_6)_2$ **(8)**.¹⁰

These amine and other 4:1 adducts of $Pd(F_6acac)$, are colorless to pale yellow. In contrast, the analogous 2:l adducts are yellow due to an absorption maximum at about 350 nm, which extends into the visible.^{2b} This band is attributed to are yellow due to an absorption maximum at about 350 nm,
which extends into the visible.^{2b} This band is attributed to
a $d_{xy} \rightarrow d_{x^2-y^2}$ transition, which occurs at low energy because of the presence of one covalently bonded hexafluoroacetylacetonate ligand in $[L_2Pd(F_6acac)]$ ⁺ F_6acac . Alkylamines, heterocyclic amines, and phosphines are expected to cause a much greater ligand field splitting than F_6 acac⁻, and as a result, the d-d transition in $L_4Pd(F_6acac)_2$ is shifted further into the ultraviolet.

As we reported earlier,^{2b} the reaction of *tert*-butyl isocyanide and Pd(F_2 acac)₂ in pentane affords Pd(F_6 acac)₂(t-C₄H₉NC)₄ **(9).** This compound decomposes on standing at room temperature but may be stored for months at -20 °C, a phenomenon that may be associated with the lack of reports of stable $Pd(RNC)₄²⁺$ salts.¹¹ However, the silicotungstate salt does not decompose at room temperature.¹²

The ¹³C NMR spectrum of 3, Table S-3, reveals that the pyridine carbons are deshielded by about 3 ppm relative to free pyridine, a result similar to that obtained for $[(py)_4Pt]^{2+}$.¹³ The effect of the metal on the 'H chemical shifts is much larger. In particular, the H(2,6) protons are deshielded due to the total magnetic anisotropy associated with the tetragonal system and appear as a quartet $[J_{H(2)-H(3)} = 5 \text{ Hz}, J_{H(2)-H(4)}$ $= 2$ Hz] at δ 9.83 in 3 and δ 9.20 in 8.

Chelation appears **to** provide a driving force for the formation of some 4:l adducts. Thus, while only a 1:l adduct is obtained from $Pd(F_6acac)_2$ and triphenylphosphine in chloroform or toluene,⁸ the bidentate phosphines $Ph_2PC_2H_4PPh_2$ and $Ph_2PCH_2PPh_2$ afforded $Pd(F_6acac)_2$ - $(Ph_2PC_2H_4PPh_2)_2$ (10) and $Pd(F_6acac)_2(Ph_2PCH_2PPh_2)_2$ (11), respectively. Similarly, while only $Pd(F_6acac)_2(Ph_3As)_2$ was isolated from the reaction of $Pd(F_6acac)_2$ with excess triphenylarsine, $Ph_2AsC_2H_4AsPh_2$ afforded $Pd(F_6acac)_2$ - $(Ph₂AsC₂H₄AsPh₂)$ ₂ (12). Chemical evidence that 10, 11, and **12** are ionic chelates of the type $(L_4Pd^{2+})(F_6acac^-)$, comes from their reaction with methanolic ammonium hexafluorophosphate to yield respectively $[(Ph_2PC_2H_4PPh_2)_2Pd](PF_6)_2$ **(13),** $[(Ph_2PCH_2PPh_2)_2Pd](PF_6)_2$ **(14),** and $[(Ph₂AsC₂H₄AsPh₂)₂Pd](PF₆)₂ (15).$ The ³¹P NMR chemical shifts in phosphorus chelate rings are characteristic and can be used for structural assignments.^{14,15} The ${^{1}}H{^{31}}P$ NMR spectra of 10 and 11 comprise singlets at 58.9 (i.e., downfield from H_3PO_4) and -32.6 ppm. The ³¹P NMR data show that both phosphines function as bidentate ligands, and the alter-

nation in chemical shift on going from **10** to **11** is indicative of chemically equivalent phosphorus contained in five- and four-membered rings, respectively:

Because of the small bite angle, bis(diphenylphosphin0) methane usually forms bridged complexes, but chelates, e.g., $(Ph_2P)_2CH_2Pd(SCN)_2$, are also known.¹⁶ Balch¹⁷ has recently summarized structural correlations in $(Ph_2P)_2CH_2$ and $(Ph₂As)₂CH₂$ complexes. In contrast to phosphorus and arsenic donors, triphenylstibine formed a 4:l adduct with Pd- $(F_6acac)_2$. In solution, $Pd(F_6acac)_2(Ph_3Sb)_4$ (16) appears to be extensively ionized and/or dissociated. The osmometric molecular weight in chloroform is 602 compared with the calculated value of 1932, and in this solvent, the ¹⁹F spectrum contains a singlet at 76.0 ppm, indicative of ionic hexafluoroacetylacetonate.

The three sulfur donors studied in this work, 1,3-dithiolene-2-thione, benzothiazole, and 1,4-dithiacyclohexane $(1,4$ -dithiane) all formed 4:1 adducts regardless of the ligand:Pd ratio. The thioketone complex $Pd(F_6acac)_2(1,3 C_3H_2S_3$ ₄ (17) is obtained as scarlet crystals in which the long-wavelength band in the electronic spectrum at 365 nm $C_3H_2S_3J_4$ (17) is obtained as scarlet crystals in which the
long-wavelength band in the electronic spectrum at 365 nm
is attributed to ligand \rightarrow metal charge-transfer processes similar to those observed in group 6B metal carbonyl complexes of this thione.^{18,19} The ligating site in benzothiazole has not been rigorously established. However, by analogy with the phenothiazine complexes of $Pd(F_6acac)_2$, shown by X-ray photoelectron spectroscopy to contain Pd-S bonds,^{2b} the ligands in (benzothiazole)₄Pd(F₆acac)₂ (18) are likely bonded through sulfur.

The cyclic thioether 1,4-dithiane forms both 1:l and 2:l complexes with metal ions, and the former may be oligometric.²⁰ Examples of complexes that have been crystallo-Examples of complexes that have been crystallographically characterized include $1,4-C_4H_8S_2(SbI_3)_2^{21}$ and $1,4-\text{C}_4\text{H}_8\text{S}_2\cdot \text{SbCl}_3$.²² The platinum complex $(1,4-\text{C}_4\text{H}_8\text{S}_2)$ - $PtCl₂$ is insoluble in common solvents and has been characterized by vibrational spectroscopy.²³ Chemical and spectroscopic data indicate that in, inter alia, $[(1,4-C_8H_1)Rh$ thioether has a boatlike conformation and functions as a bidentate ligand.²⁴ $(1,4-C_4H_8S_2)$]PF₆ and $[(\eta^3-RC_3H_4)Pd(1,4-C_4H_8S_2)]P\overline{F}_6$, the

Several lines of evidence indicate that in $Pd(F_6acac)_2(1,4 C_4H_8S_2$ ₂ (19) the thioether ligand has a similar conformation and that **19** can be written as $[(\eta^2 - 1, 4 - C_4H_8S_2)_2Pd](F_6acac)_2$. The X-ray photoelectron spectra of this material and of $[(1,4-C_4H_8S_2)_2Pd](PF_6)_2$ (20), prepared by metathesis with ammonium hexafluorophosphate, reveal that the Pd $(3d_{5/2})$ and *S* (2s) core binding energies are at 388.3 and 288.5 eV, respectively (relative to C $(1s)$ at 285.0 eV), indicating that both sulfur atoms in 1,4-dithiane are bonded to palladium. The same conclusion is reached from a consideration of the pro-

^{*a*} The number in parentheses is the estimated standard deviation in the last significant figure. ^b Primed atoms are related to unprimed atoms by an inversion operation through the Pd atom.

Figure 1. ORTEP drawing of the Pdl molecule using 30% probability ellipsoids. The Pd atom is at an inversion center.

ton-decoupled I3C NMR spectrum of *19,* which shows a single resonance at 36.3 ppm due to the dithiane ring methylene carbons. By analogy with the published spectra of (1,4- $C_4H_8S_2$)Pt X_2 ,¹⁹ Raman bands in 19 and 20 at 389 and 417 cm-' are attributed to ring bending modes and those at **307** and 634 cm⁻¹ to Pd-S and C-S stretching, respectively. The strong bands of PF_6^- salt match those of the hexafluoroacetylacetonate analogue, both in the solid state and in methanol solution, suggesting that changing counterions has little effect on the gross structure of the $[(1,4-C_4H_8S_2)_2Pd]^{2+}$ core. Further, there is a lack of coincidence between the Raman and infrared spectra of **20,** which we interpret to mean that the $[(1,4-C_4H_8S_2)_2Pd]^{2+}$ ion has a centrosymmetric structure: structure:

compounds, an X-ray crystal structure determination on Pd-

Figure 2. ORTEP drawing of the Pd2 molecule using 30% probability ellipsoids. The Pd atom is at an inversion center.

$(F_6acac)_2(4\text{-ClC}_5H_4N)_4$ was carried out.

Description of the Structure

The two crystallographically independent $Pd(F_6acac)_2(4 ClC₅H₄N)₄$ molecules contain inversion centers of symmetry at their Pd atom positions (Figures 1 and 2). The molecules are well separated in space with no unusually short intermolecular distances. A tabulation of selected intramolecular distances and angles is presented in Table I. It is seen that displacement of both fluorinated β -diketonate ligands has occurred. Both molecules have coordination cores that are comprised of palladium and four nitrogen atoms from the chloropyridine ligands. The $PdN₄$ group is crystallographically required to be planar. The planes of the pyridine rings are approximately perpendicular to the PdN4 plane (Table 11) and $d(Pd-N)_{av}$ is 2.027 Å, in close agreement with 2.038 Å in $[(bpy)₂Pd(H₂O)₂](NO₃)₂²⁵$ Two oxygen atoms, one from each F_6 acac, occupy axial positions, in what may be described

⁽²⁵⁾ P. **C.** Chieh, J. Chem. *SOC., Dalron Trans.,* **1643 (1972).**

Figure 3. ORTEP stereoview of the Pdl molecule. The Pd2 molecule has a similar geometry and is not shown.

Figure 4. ORTEP drawing of the PdN_4O_2 coordination core with selected distances **(A)** and angles (deg). Distances and angles are averages for the two unique molecules except for the Pd distances to 01B and **OlD,** which are quite different. All averages are within 5σ of the actual values. The Pd is at an inversion center.

as a grossly tetragonally distorted octahedral coordination geometry, with long (3.02 **A)** palladium-oxygen contacts. Figure **3** shows an **ORTEP** stereoview of the Pd2 molecule, and an **ORTEP** drawing of the coordination core with selected distances and angles is presented in Figure **4.** It is apparent that the distances and angles within the cores of the two independent molecules are quite similar (Figure **4** and Table I). These chemically equivalent distances and angles are within 5σ , except for the longer Pd-O1B and $-$ O1D distances, which differ by 0.25 **A.** The distances and angles shown in Figure **4** have been averaged over the two independent molecules.

Both hexafluoroacetylacetonate groups display similar distances and angles. Within each of these moieties, the **C-0** and C(methine)-C(carbony1) distances are also similar and indicative of a delocalized, symmetrical enolate structure, in contrast to the alternating bond lengths found in the bis- (pyridine) complexes of copper and zinc hexafluoroacetylacetonates.²⁶ The backbone of the F_6 acac group containing 0 **1** C and 01 D **is** planar with a maximum atomic displacement from the least-squares plane of 0.01 **A** (Table 11, plane 7). The other, however, containing 01A and 01B is slightly twisted about the $C(11)$ -C12A and -C12B bonds so that O1A and 01B are 0.04 **A** below and above the least-squares plane, respectively.

Experimental Section

Infrared spectra were obtained as Nujol mulls on an instrument with grating optics; frequencies of peak maxima are believed to be accurate to within **45** cm-'. Ultraviolet spectra were recorded on a Cary 14 spectrometer. A Varian XL-100 spectrometer was used

to obtain NMR spectra; internal $(CH₃)₄Si$ or CFCl₃ and external H3P04 were employed as references. Raman spectra were recorded on a Spex Ramalog instrument equipped with spinning sample holders. The conductivity measurements were made with a dip type cell having platinized electrodes.

 $[(CH₃)₂NH_kPd(F₆acac)₂(1)$. A stream of dry dimethylamine was passed through a solution of 0.3 g of $Pd(F_6acac)_2$ in 7 mL of pentane. Yellow crystals of $[(CH_3)_2NH]_2Pd(F_6acac)_2$ began to separate. The flow of amine was continued until white crystals of **1** precipitated; mp 137-139 °C dec. The product was collected on a filter, washed with pentane, and air-dried. The yield was 0.3 g (75%).

 $(py)_4Pd(F_6acac)_2$ (3). To 0.19 g of $Pd(F_6acac)_2$ in 10 mL of pentane was added 0.5 mL of pyridine. The white solids that formed were recrystallized from methylene chloride-hexane to give 0.20 g (66%) of 3 as white needles, mp 193 $^{\circ}$ C dec.

 $[(py)_4Pd](PF_6)_2$ (8). Methanolic ammonium hexafluorophosphate was added to 0.65 g of **3** dissolved in *5* mL of warm methanol. Recrystallization of the resulting white precipitate from acetonemethanol gave 0.4 *g* (73%) of white crystalline product.

(Ph₂PC₂H₄PPh₂)₂Pd(F₆acac)₂ (10). To 0.80 g of Ph₂PC₂H₄PPh₂ (2 mmol) in 10 mL of benzene was added with stirring 0.52 g (1 mmol) of Pd(F,acac), in *5* mL of the same solvent. The product separated as granular white solids, which were collected on a filter, washed with fresh solvent, and vacuum-dried. The yield was 1.25 g (95%). An analytical sample was obtained by recrystallization from acetoneethanol; mp 212-213 **C.*

 $(\text{Ph}_3\text{Sb})_4\text{Pd}(F_6\text{acac})_2$ (16). A solution of 0.38 g (1.1 mmol) of Ph₃Sb in 10 mL of warm hexane was added with stirring to 0.13 g (0.25 mmol) of $Pd(F_6, acac)_2$ in 3 mL of hexane. The reaction mixture was concentrated with a nitrogen jet to ca. 8 mL. The pale yellow crystalline product was then collected on a filter and vacuum-dried. The yield was 0.16 g (33%). The X-ray powder pattern was unique and did not show lines due to the starting materials.

 $(1,4-C_4H_8S_2)_2Pd(F_6acac)_2$ (19). A solution of 0.26 of Pd($F_6acac)_2$ in 5 mL of pentane was added to a solution of 0.13 g of $1,4-C_4H_8S_2$. **in** 20 mL of pentane. The pale yellow crystalline product, mp 187 "C, was collected on a filter and then vacuum-dried. The yield was 0.31 **g** (82%). Raman spectrum (6265-A excitation): 2475 **(w),** 1550 (m), 1315 (s), 1065 (s), 940 (w), 740 (m), 665 (m), 640 (s), 470 (m), 395 (vs), 310 (s), 350 (s) cm-I.

 $[(1,4-C_4H_8S_2)_2Pd](PF_6)_2$ **(20).** Excess methanolic NH₄PF₆ was added to a yellow solution of 0.76 g (1 mmol) of **19,** in 6 mL of methanol. The solids that separated were recrystallized by slow evaporation of an acetone-ethanol solution to give 0.52 g of **20** (82%) as light yellow microcrystals. Raman spectrum (6265-A excitation): 2950 (w), 1425 (w), 974 (w), 741 **(s),** 660 (w), 634 **(s),** 417 (s), 389 (vs), 307 (s). X-ray photoelectron spectrum (relative to $C(1s) = 285.0$ eV): Pd(3d_{5/2}), 388.3; S(2s), 228.5 eV.

Structure Determination. Since good crystals of Pd(F_6 acac)₂(py)₄ were not obtained, synthesis of a substituted derivative was undertaken. 4-Chloropyridine was prepared by neutralization of the commerically available hydrochloride salt with aqueous sodium hydroxide. The Table **I1**

Least-Squares Planes^a

2

^a Planes were calculated with use of unit weights. The equation of the plane is of the form $Ax + By + Cz - D = 0$, where A, B, C, and D are constants and x, y, and z are orthogonalized coordinates. ^b Atoms in the plane. ^c

free base was isolated by extraction into methylene chloride, followed **by** evaporation. A solution of 2.0 mmol of 4-chloropyridine in 3 mL of benzene was added to 0.26 g (0.5 mmol) of $Pd(\hat{F}_6 a c a c)_2$ in 2 mL

of the same solvent. Octane was added to induce the precipitation of fine white needles of $Pd(F_6acac)_2(4-CIC_5H_4N)_4$, mp 187 °C dec. Anal. Calcd: C, 37.0; H, 1.8; N, 5.7. Found: C, 36.7; H, 1.6; N,

Table **111.** Positional and Thermal Parameters and Their Estimated Standard Deviations'

a The form of the anisotropic thermal parameter is $exp[-l_4(B_{11}h^2a^{*2} + B_{22}k^2b^{*2} + B_{33}l^2c^{*2} + 2B_{12}hkab^{*}c^{*} + 2B_{13}hla^{*}c^{*} + 2B_{23}klb^{*}c^{*})].$ For all H atoms $B = 6.0000(0) A^2$.

5.7. If the needle crystals were not collected quickly and, instead, the reaction mixture was allowed to stand overnight, the product consisted of clear, pale yellow cube-shaped crystals of a second polymorph, mp 190 °C dec. Anal. Found: C, 37.4; H, 1.8; N, 5.7. The infrared spectra of both polymorphs were the same but the X-ray powder diffraction pattern of each was unique. The cubic crystals were used in the structure determination.

A crystal of $Pd(F_6acac)_{2}(4-CIC_5H_4N)_4$, $PdCl_4F_{12}O_4N_4C_{34}H_{18}$ (formula weight = 974.7), of approximate dimensions 0.35×0.25 **X** 0.20 mm was selected and **used** in the structure determination. The crystal was found to belong to the monoclinic crystal class by the Enraf-Nonius **CADQ-SDP** peak search, centering, and indexing computer

programs.²⁷ The space group $P2_1/c$ (No. 14) was chosen from the systematic absences observed during data collection and was verified by successful solution and refinement (vide infra). **A** Delaunay reduction calculation (PROGRAM TRACER)²⁷ did not indicate a higher order space group. The unit cell dimensions were determined by least-squares refinement of the angular settings of 25 peaks (Mo *Ka* radiation, $\lambda = 0.71069$ Å) centered on the diffractometer and are $a = 19.356$ (3) \AA , $b = 18.902$ (3) \AA , $c = 10.636$ (2) \AA , $\beta = 100.12$ (1)^o, and $V = 3831 \text{ Å}^3$. The density is calculated to be 1.690 g cm⁻³ with the assumption of $Z = 4$.

Data collection was carried out with use of a **CAD4** Nonius automatic diffractometer. Background counts were measured at both ends of the scan range with a variable rate ω -2 θ scan equal, at each side, to one-fourth of the scan range of the peak. In this manner, the total duration of measuring backgrounds is equal to half of the time required for the peak scan. The intensities of three standard reflections were measured every $1^{1}/_{2}$ hours of X-ray exposure and no decay with time was noted. The intensities of 7506 $(\pm h, +k, +l)$ quadrant) unique reflections were measured at room temperature in the range $2\theta = 0-52^{\circ}$ with use of graphite-monochromated Mo K α radiation and a variable-rate ω -2 θ scan technique. After correction for Lorentz, polarization, and background effects (but not for ab-
sorption, $\mu = 8.24 \text{ cm}^{-1}$),²⁸ 3510 reflections were judged observed [F_o^2 $\geq 2.0\sigma(F_{0}^{2})$] and were used in all subsequent calculations.²⁷

Conventional heavy-atom techniques were used to solve the structure, and refinement, with all nonhydrogen atoms thermally anisotropic and hydrogen atoms thermally isotropic by full-matrix least-squares methods (499 variables), converged R and R_w to their

 \bar{z}

final values of 0.047 and 0.067, respectively.²⁹ The error in an observation of unit weight was determined to be 1.35 by using a value of 0.04 for p in the $\sigma(I)$ equation. Hydrogen atom positional parameters were located by difference Fourier analysis and were included in the refinement but with fixed thermal parameters. The final difference Fourier map did not reveal any chemically significant features.

The final atomic coordinates with their esd's and the final thermal parameters are given in Table **111.** Tables of observed and calculated structure factor amplitudes are available as supplementary material.

The unit cell of $Pd(F_6acac)_2(4-ClC_5H_4N)_4$ contains two crystallographically independent molecules. The two palladium atoms, Pd 1 and Pd2, are located on special position 0, 0, 0 and $1/2$, 0, 0 and therefore are at inversion centers of symmetry. Figures 1 and 2 show ORTEP drawings of the two independent molecules with labeling schemes.

⁽²⁷⁾ Calculations were carried out **on** a PDP **11/34** computer using the Enraf-Nonius SDP programs. This crystallographic computing package is described by B. A. Frenz in "Computing in Crystallography", H. Schenk, R. Olthof-Hazekamp, R. van Koningsveld, and G. C. Bassi, **Eds.,** Delft University Press, Delft, Holland, 1978, pp 64-71.

⁽²⁸⁾ Intensity data were processed as described in 'CAD4 and SDP Users Manual", Enraf-Nonius, Delft, Holland, 1978. The net intensity I is given by $I = (K/NPI)(C-2B)$ where $K = 20.1166$ (attenuator factor), NPI = ratio of fastest possible scan rate to scan rate for the measure-NPI = ratio of fastest possible scan rate to scan rate for the measure-
ment, C = total count, and B = total background count. The standard
deviation in the net intensity is given by $\sigma^2(I) = (K/NPI)^2 [C + 4B +$ $(pI)^2$] where p is a factor used to downweight intense reflections. The observed structure factor amplitude F_0 is given by $F_0 = (I/Lp)^{1/2}$ where $Lp =$ Lorentz and polarization factors. The $\sigma(I)$'s were converted to the estimated errors in the relative structure factors $\sigma(F_o)$ by $\sigma(F_o)$ = $\frac{1}{2}(\sigma(I)/I)F_{\rm o}$.

⁽²⁹⁾ The function minimized was $\sum w([F_0] - [F_c])^2$ where $w = 1/\sigma^2(F_0)$. The unweighted and weighted residuals are defined as $R = (\sum ||F_o|$ an weight and $R_w = \left[\left(\sum w([F_0] - [F_0])\right)^2 / \left(\sum w[F_0]\right)^2\right]^{1/2}$. The error in an obervation of unit weight is $\left[\sum w([F_0] - [F_0])^2 / (\text{NO} - \text{NV})\right]^{1/2}$, where NO and NV are the number of observations and variables, respectively. Atomic scattering factors were taken from the 'International Tables for X-ray Crystallography", Vol. **111,** Kynoch Press, Birmingham, England, 1962. Anomalous dispersion corrections from the same **source** were used for palladium.
