Corrections and Additional Insights to the Synthesis and Characterization of Tetramethylammonium Superoxide $[(Me_4N)O_2]$

Kenneth Yamaguchi, Thomas S. Calderwood, and Donald T. Sawyer*

Received October 7, 1985

During the past 15 years the biochemistry¹ and chemistry²⁻⁵ of superoxide ion ($O_2^{\bullet-}$) has been thoroughly characterized.^{2,5} Superoxide ion can be generated in aqueous solutions from O_2 by pulse radiolysis⁶⁻⁹ and from H_2O_2 by photolysis.^{10,11} Stable solutions of $O_2^{\bullet-}$ can be prepared in aprotic solvents by electrochemical methods,^{2-5,12} by the base-induced decomposition of H_2O_2 ,^{13,14} and by solubilizing KO₂ with 18-crown-6-ether.¹⁵⁻¹⁸ These methods are hindered by the low fluxes of $O_2^{\bullet-}$ produced and by the presence of other reactive species.

Tetramethylammonium superoxide $[(Me_4N)O_2]$, which was first prepared some 20 years ago from KO₂ and (Me₄N)OH·5H₂O via a solid-phase metathesis reaction,¹⁹ is soluble in aprotic solvents and represents a convenient source of O₂^{-.} A previous paper²⁰ described our efforts to optimize the synthetic procedure and to characterize (Me₄N)O₂. Here we wish to report (a) that the purported dimer of (Me₄N)O₂ in the previous study²⁰ actually is a peroxide adduct of acetonitrile [MeC(OO⁻)=NH], which hydrolyzes to the base adduct of acetamide [MeC(O⁻)(OH)NH₂], (b) that the previous synthetic procedure²⁰ can yield substantial amounts of (Me₄N)OH and (Me₄N)OOH, and (c) that a purer and more consistent product is obtained in higher yields when (Me₄N)OH·H₂O or (Me₄N)₂CO₃ is combined with KO₂ to produce (Me₄N)O₂.²¹

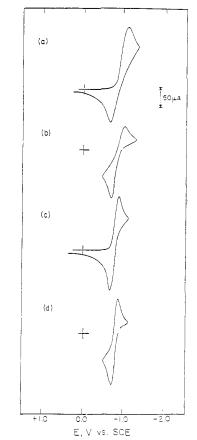

Figure 1. Cyclic voltammograms for (a) 1.6 mM O_2 in MeCN, (b) 2.55 mM (Me₄N) O_2 in MeCN, (c) 2.1 mM O_2 in Me₂SO, and (d) 4.83 mM (Me₄N) O_2 in Me₂SO (0.1 M tetraethylammonium perchlorate) at a Pt electrode (area 0.23 cm²).

As noted in the previous $paper^{20}$ the isolated products from the solid-phase metathesis reactions, when dissolved in acetonitrile, exhibit UV-visible absorption spectra that are widely different for the various synthetic conditions and for the various solution conditions with a given product. After a solution is prepared, the absorption maxima at 254 nm increases and the shoulder at 290 nm decreases as a function of time.

Authentic electrogenerated $O_2^{\bullet-}$ exhibits an absorption maximum at 253 nm.^{3,4} When (Me₄N)OH·H₂O or KOH is added

(21) The use of either $(Me_4N)OH \cdot H_2O$ or $(Me_4N)_2CO_3$ avoids the presence of excess water in the starting materials and thereby lowers the amount of KO₂ required in the synthesis:

 $(Me_4N)OH \cdot H_2O(s) + 3KO_2(s) \xrightarrow{NH_3}$

 $(Me_4N)O_2 + 3KOH(s) + \frac{3}{2}O_2$

$$(Me_4N)_2CO_3(s) + 2KO_2(s) \xrightarrow{and 3} 2(Me_4N)O_2 + K_2CO_3(s)$$

The (Me₄N)OH·H₂O solid was prepared by drying (Me₄N)OH·5H₂O in vacuo at 90 °C for 2 days. The solid (Me₄N)₂CO₃ was prepared by passing dry CO₂ gas over (Me₄N)OH·H₂O. The resulting liquid was dried in vacuo at 90 °C for 1.5 days. Each of the solid synthesized bases was mixed with the appropriate amount of solid KO₂ and rotated under vacuum for 2 days with 40 g of 3-mm glass beads. Two liquid-ammonia extractions were performed as described previously.²⁰ The isolated product [80–90% (Me₄N)O₂] was combined with an equimolar amount of KO₂. The mixture was ground with 40 g of 3-mm glass beads under vacuum for 1 day prior to two extractions with liquid NH₃. The refined solid product had an assay of greater than 93% (Me₄N)O₂ on the basis of its magnetic susceptibility (Gouy method).

to MeCN, a slow reaction with the solvent occurs and the solution develops an absorption spectrum²² that is analogous to that for impure $(Me_4N)O_2$ samples in MeCN.

If a one-to-one combination of H_2O_2 and $(Me_4N)OH \cdot H_2O$ is added to MeCN, the solution immediately exhibits a strong absorption band at 290 nm [purportedly due to the dimer of $(Me_4N)O_2$ in the previous study]²⁰ as well as a band at 254 nm. Addition of H₂O causes the 290-nm band to disappear and the 256-nm band to increase proportionately (there is an isosbestic point at 267 nm). Neither solution contains any $O_2^{\bullet-}$ on the basis of ESR and electrochemical measurements.

The ESR spectra for authentic pure $(Me_4N)O_2^{21}$ dissolved in MeCN and Me₂SO are similar to those reported previously for electrogenerated O2 •. 3,4,20 Magnetic susceptibility measurements of $(Me_4N)O_2$ (synthesized by the new procedure)²¹ indicate that it is about 93% pure [KO₂ (96%) used as the reference standard]. The magnetic moments (corrected for diamagnetism) for KO₂ and $(Me_4N)O_2$ are 1.89 ± 0.05 μ_B for each material.

Figure 1 illustrates the cyclic voltammograms for O_2 and $(Me_4N)O_2$ in MeCN and Me₂SO. On the basis of the voltammetric peak currents^{20,23} the solid (Me₄N)O₂ (93% pure), when dissolved in MeCN, yields 60-80% electroactive O_2^{-} and, in Me₂SO, 70–90% $O_2^{\bullet-}$. This is in accord with the electrogeneration efficiencies for O2⁻⁻ in MeCN and Me2SO and reflects the respective stability of O_2^{-} in these solvents.

The water-induced formation of HO_2^- from $O_2^{\bullet-}$, $6^{-9,13}$ the attack by HO₂⁻ and OH⁻ of acetonitrile,^{13,26} and the subsequent hydrolysis of the adducts are outlined by eq 1-5.

$$O_2^{\bullet-} + H_2 O \rightleftharpoons HO_2^{\bullet} + OH^- \quad pK_a = 4.88$$
 (1)

$$O_2^{\bullet-} + HO_2^{\bullet} \rightarrow O_2 + HO_2^{-} \qquad k_2 = 1.0 \times 10^8 \text{ M}^{-1} \text{ s}^{-1} \quad (2)$$

$$H_2O_2 + OH^- \Longrightarrow HO_2^- + H_2O \qquad pK_a = 11.8$$
 (3)

$$MeC \equiv N + HO_{2}^{-} \xrightarrow{fast} \left[MeC \swarrow_{OOH}^{N^{-}} \longrightarrow MeC \underset{OO}{=} NH_{1}^{-} \xrightarrow{H_{2}O_{1}} \right] \xrightarrow{H_{2}O_{1}} \\ \lambda_{max} = 290 \text{ nm} \\ MeC \underset{OO}{\longrightarrow} NH_{2} \longrightarrow MeC \underset{O}{\longrightarrow} NH_{2} + \frac{1}{1} \sqrt{2}O_{2} \quad (4) \\ \lambda_{max} = 254 \text{ nm} \\ MeC \underset{OH}{=} N + OH^{-} \xrightarrow{slow} \left[MeC \underset{OH}{=} N^{-} \longrightarrow MeC \underset{O}{=} NH_{1}^{-} \xrightarrow{H_{2}O_{2}} \right] \xrightarrow{H_{2}O_{2}} \\ \lambda_{max} = 290 \text{ nm} \\ MeC \underset{OH}{\longrightarrow} NH_{2} \underset{O}{\longleftarrow} MeC(O)NH_{2} + OH^{-} \quad (5) \\ \lambda_{max} = 254 \text{ nm} \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longleftarrow} MeC(O)NH_{2} + OH^{-} \quad (5) \\ \lambda_{max} = 254 \text{ nm} \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} + OH^{-} \quad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} + OH^{-} \quad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} + OH^{-} \quad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} + OH^{-} \quad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MeC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MeC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MEC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MEC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MEC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MEC \underset{O}{\longrightarrow} NH_{2} \underset{O}{\longrightarrow} MEC(O)NH_{2} \underset{O}{\longrightarrow} OH^{-} \qquad (5) \\ MEC \underset{O}{\longrightarrow} NH_{2} \underset{O$$

The coincidence of the 254-nm absorption bands for O2* and MeC(OH)(O⁻)NH₂ in MeCN precludes spectrophotometric assays for superoxide ion. Either magnetic susceptibility measurements of the solid salts or voltammetric measurements of O2. solutions (Figure 1) are recommended for reliable assays.

In summary, the original synthetic procedure 19,20 for $(Me_4N)O_2$ can yield an impure product that contains (Me₄N)OOH and

 $(Me_4N)OH \cdot H_2O$ (slightly soluble in liquid ammonia). The UV-visible spectrum for pure $(Me_4N)O_2$ (synthesized by the new procedure) in MeCN is identical with that for $O_2^{\bullet-}$ produced by electrosynthesis from O₂ [$\lambda_{max} = 253 \text{ nm} (\epsilon = 3.0 \pm 1.0 \text{ mM}^{-1} \text{ cm}^{-1})$]. The amount of O₂⁻⁻ that results from the dissolution of (Me₄N)O₂ in MeCN or Me₂SO makes it a more efficient source than electrosynthesis. The inefficiency of the latter process yields substantial amounts of OH^- and HO_2^- in the product solution.

Synthesis and Structural Characterization of Methylenebis(phosphinic acid) $(CH_2(PH(O)OH)_2)$

Christopher King,^{1a} D. Max Roundhill,*^{1a} and Frank R. Fronczek^{1b}

Received July 23, 1985

Recently the binuclear tetraanionic complex tetrakis(µ-pyrophosphito)diplatinum(II) ($Pt_2(\mu - P_2O_5H_2)_4^{4-}$) has attracted considerable interest because of its intense luminescence in aqueous solution at ambient temperature.² The triplet excited state is both a strong reductant and oxidant,³ and it also reacts as a free radical to abstract a hydrogen atom from the C-H bond of both isopropyl alcohol and toluene.⁴ The photophysics and photochemistry of $Pt_2(\mu-P_2O_5H_2)_4^{4-}$ have been explained on the basis of Gray's molecular orbital model, whereby a close separation between the $A_{1g}(d\sigma^*)$ and $A_{2u}(p_z)$ orbital levels on Pt_2 is induced by intermetallic interaction $A_{2u}(p_z)$ along the z axis.⁵

The extension and development of this chemistry requires the synthesis of new ligands. Pyrophosphorous acid is a hydrolytically unstable compound, which can be obtained in the pure state only with some difficulty.⁶ Synthetic routes to μ -pyrophosphito complexes are thereby very limited; and indeed the synthesis of $Pt_2(\mu-P_2O_5H_2)_4^{4-}$ circumvents these problems by effecting the condensation of phosphorous to pyrophosphorous acid as a template reaction with the precursor platinum complex. Such a method is not generally adaptable to other metal complexes. We therefore need a pyrophosphite analogue compound that has
