Received December 16, 1994[⊗]

The relevant N,N-coordinating ligands are RN=C(H)-C(H)=NR (general abbreviation D, specific abbreviations D^{\dagger} and D^{2} for R = cyclohexyl and p-tolyl, respectively) and $[RN=C(H)-C(=O)-NR]^{-}$ (abbreviations A, A^{\dagger}, A²). Oxidation of cis- and trans-Ru^{II}D₂Cl₂ by aqueous cerium(IV) (H₂O₂ can also be used for trans-RuD₂Cl₂) affords in excellent yield the amide complexes cis- and trans-Ru^{III}DACl₂ with retention of parental isomeric structure. Spectral and magnetic characterization data of the complexes are reported along with the X-ray structures of cis-RuD¹₂Cl₂PhMe and cis-RuD¹A¹Cl₂CH₂Cl₂. The ruthenium(III)—ruthenium(II) couples of the complexes follow $E_{1/2}$ systematics (other things remaining the same in each case): geometry, cis > trans; ligand, D > A; substituent, p-tolyl > cyclohexyl. The RuIIID2Cl2+ moiety has been electrogenerated in solution, and cis-[Ru^{III}D¹2Cl₂]ClO₄ has been isolated and characterized in the pure state. The conversion RuD₂Cl₂ \rightarrow RuDACl₂ actually occurs via RuD₂Cl₂+, which reacts with water, affording the amide complex. The reaction is first order with respect to both RuD₂Cl₂⁺ and H₂O, and the activation parameters are $\Delta H^{\dagger} = 12.5$ kcal mol⁻¹ and $\Delta S^{\dagger} =$ -29.8 eu in the case of trans-RuD²2Cl₂. It is proposed that the water molecule adds to the azomethine function and the α-hydroxy amine function of the adduct is rapidly oxidized via an induced electron transfer pathway. The net reactions are as follows: $RuD_2Cl_2 \rightarrow RuD_2Cl_2^+ + e$; $RuD_2Cl_2^+ + H_2O \rightarrow RuDACl_2 + 2e + 3H^+$. A crucial reaction condition appears to be the easy accessibility of two oxidation states of the metal ion related by facile transfer of one electron, the higher oxidation state being sufficiently polarizing to induce water binding at the aldimine site. Crystal data for the complexes are as follows: cis-RuD¹₂Cl₂PhME, crystal system monoclinic, space group $P2_1/c$, a = 14.808(6) Å, b = 19.442(7) Å, c = 13.989(6) Å, $\beta = 117.18(3)^\circ$, V = 3583(2) Å³, $Z = 117.18(3)^\circ$ 4, R = 3.70%, $R_w = 4.31\%$; cis-RuD¹A¹Cl₂·CH₂Cl₂, crystal system monoclinic, space group $P2_1/c$, a = 11.295(4)Å, b = 27.064(14) Å, c = 12.064(4) Å, $\beta = 107.52(2)^{\circ}$, V = 3517(2) Å³, Z = 4, R = 6.53%, $R_{w} = 6.95\%$.

Introduction

Incorporation of oxygen functions into organic substrates assisted by metal coordination is a reaction class of fundamental import in chemistry. This work is concerned with the reaction of eq 1 where the functional transformation aldimine \rightarrow amide

$$\sum_{H} c = N \xrightarrow{M} - \sum_{O} c - N \xrightarrow{M} (1)$$

occurs. Our objectives are to search for reactive systems and to scrutinize the scope and nature of this interesting but little-known reaction. Recently we observed that certain pyridine-2-carboxaldimine complexes of rhenium and ruthenium incorporating the chelate motif 1 undergo the transformation of eq $1.^{1.2}\,$ This has prompted us to explore chelates of simple $\alpha\text{-diimines}$ as possible reactive substrates. We were encouraged by the reports that amides are among the products of the otherwise complicated oxidation of $\alpha\text{-diimine}$ chelates of iron.³

Herein we disclose the facile and clean conversion of the ruthenium α -diimine motif 2 to the amide—imine motif 3. A

family of parent and product complexes have been characterized. Isomeric metal geometries are conserved in the reaction which proceeds via metal oxidation and ligand aquation and oxidation. Certain general governing principles are defined.

Results and Discussion

Parent α-Diimine Complexes. These are of the known^{4,5} general types *cis*- and *trans*-Ru^{II}D₂Cl₂, **4a** and **4b** (D = α -diimine, Figure 1). The two R groups used here are cyclohexyl (D = D¹) and *p*-tolyl (D = D²). Our preparative methods are summarized in Scheme 1. We have found Ru(Me₂-

SO)₄Cl₂ to be an excellent and generally applicable starting material for synthesis. All four complexes have been isolated in stable forms. Earlier, trans-RuD12Cl2 was observed only as an occasional product in a different synthetic method.4

Amide Complexes. Synthesis. Oxidation of cis- and trans-RuD₂Cl₂ with aqueous cerium(IV) afford, in excellent yields, the dark-colored amide complexes of trivalent ruthenium cisand trans-Ru^{III}DACl₂, 5a and 5b (Figure 1), with retention of parental isomeric structure (Scheme 1). While D is neutral, the amide-imine ligand is N-bonded to ruthenium(III) in the anionic deprotonated form, A^- . Specific A's are A^1 (R = cyclohexyl) and A^2 (R = p-tolyl). Even when excess oxidant is used, only one imine function in one of the α -diimine ligands is oxidized to amide; the second diimine ligand remains unaffected. Thus RuDACl₂ is the only product of oxidation.

Spectra. Selected spectral data are set out in Tables 1 and 2. The paramagnetic $(t_2^5, S = \frac{1}{2}, Table 2)$ RuDACl₂ complexes exhibit amide bands in the IR region (1590-1630 cm⁻¹), LMCT excitation in the visible region (Table 1), a relatively weak feature in the near-IR region (1400-1800 nm, Table 1, Figure 2), and rhombic EPR spectra (Table 2, Figure 2).

The EPR spectra have been analyzed⁶ with the help of d⁵ g-tensor theory.^{7,8} We only quote here the important result that in each case the computed energy of a ligand field transition within the t₂ shell split by low-symmetry components fits well with the energy of the observed near-IR band (Table 2). For

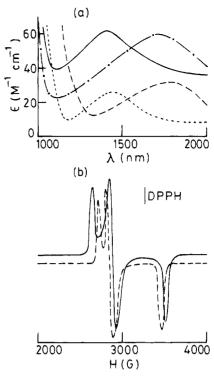

Figure 2. (a) Near-IR spectra of cis-RuD²₂Cl₂⁺ (---), trans-RuD²₂- Cl_2^+ (---), cis-RuD²A²Cl₂ (-·-), and trans-RuD²A²Cl₂ (-) in dichloromethane solution. (b) X-Band EPR spectra of cis-RuD²₂Cl₂⁺ (---) and trans-RuD2A2Cl2 (-) in dichloromethane-toluene glass

isomeric RuDACl2 complexes, both the predicted and observed energies of the band follow the order trans > cis. This trend is also consistent with ligand field description of t2 splitting.9 The trans > cis inequality is of diagnostic value for isomeric structure assignment.

The optical spectra of the RuD₂L₂ isomers have a dominant MLCT band in this visible region (Table 1) in general agreement with previous findings.4

Structure. The imine → amide oxidation process has been authenticated by structure determination in the one case where single crystals could be successfully grown (as solvates): cis-RuD¹₂Cl₂•PhMe and cis-RuD¹A¹Cl₂•CH₂Cl₂. Molecular views of the two complexes excluding solvents of crystallization are shown in Figures 3 and 4. Selected bond distances and angles are listed in Tables 3 and 4.

Both complexes have the cis-RuN₄Cl₂ configuration showing that the oxidation process is stereoretentive. The cyclohexyl groups in the complexes uniformly have chair conformation. The amide function in the oxidized complex lies trans to a chlorine site. In this manner the three anionic donors (amide N, two chlorides) are positioned meridionally. The possible facial isomer which would have formed if oxidation occurred cis to a chlorine site has not been observed in any of the oxidations.

The average Ru-N length in the RuD¹ chelate ring is longer by ~ 0.02 Å in RuD¹A¹Cl₂ compared to that in RuD¹2Cl₂. This can be attributed to the inferior back-bonding (t₂(Ru) $\rightarrow \pi^*(D)$) ability of ruthenium(III) compared to ruthenium(II).¹0 The average lengths of the Ru-Cl bond (no back-bonding) expectedly shows the reverse trend, being shorter in the amide complex by 0.04 Å.

The coordinated amide function in $RuD^1A^1Cl_2$ deviates significantly from planarity, corresponding to a rotation around the N(1)-C(7) bond by 10.8°, which is also the dihedral angle between the nearly perfect planes of Ru, N(1), C(1), and C(7) (mean deviation 0.004 Å) and of N(1), C(7), O(1), and C(8) (mean deviation 0.012 Å) in the RuA¹ chelate ring. The Ru-N(1), N(1)-C(7), and C(7)-O(1) lengths in our complex compare well with the corresponding lengths of the coordinated amide function in $Ru^{III}(NH_3)_4(glycinamidato)^{2+}.$

Although single crystals could not be grown for the other complexes concerning us here, the present structural results taken collectively with spectroscopic data considered above and

electrochemical findings noted below testify to the correctness of the geometrical structures of the complexes as presented in Figure 1. Last, we note that the bond parameters of cis-RuD¹₂- Cl_2 are similar to those of **4a** (R = isopropyl).⁵

Metal Redox. Both RuD2Cl2 and RuDACl2 display nearly reversible (peak-to-peak separation, 60-80 mV) one-electron cyclic voltammetric responses due to stereoretentive ruthenium(III)-ruthenium(II) redox, eqs 2 and 3. The crucially important RuD₂Cl₂⁺ species will be considered further in the next section.

$$cis/trans$$
-Ru^{III}D₂Cl₂⁺ + e $\rightleftharpoons cis/trans$ -Ru^{II}D₂Cl₂ (2)

$$cis/trans$$
-Ru^{III}DACl₂ + e $\rightleftharpoons cis/trans$ -Ru^{II}DACl₂ (3)

Certain trends of the reduction potentials ($E_{1/2}$ vs SCE) listed in Table 5 will now be noted. For low-spin $t_2^5-t_2^6$ couples, the trend cis > trans which is observed in the present complexes is diagnostic of isomeric structures. 12,13 This arises from the better stabilization of the t26 (ruthenium(II)) configuration in the cis compared to the trans configuration via back-bonding.

For a given R and geometry, the $E_{1/2}$ of RuDACl₂ is lower than that of RuD₂Cl₂ by a remarkable 0.5-0.6 V. The better stabilization of the ruthenium(III) state by the deprotonated amide function (A-) compared to aldimine function is also reflected in bond lengths of RuD¹A¹Cl₂: the Ru-N(amide) length is shorter than the average Ru-N(imine) lengths by 0.07 Å (Table 4). Last, we note that the $E_{1/2}$ of any R = p-tolyl complex is higher than that of the R = cyclohexyl congener because the cyclohexyl group is a better electron donor than the p-tolvl group.

Ru^{III}D₂Cl₂⁺. This species is the oxidant in the ruthenium(III)—ruthenium(II) couple of eq 2. It is shown in the next section that the conversion of RuD₂Cl₂ to RuDACl₂ proceeds via RuD₂Cl₂⁺. Characterization data for the latter are given here.

The RuD₂Cl₂⁺ cation has been quantitatively generated in dry dichloromethane solution by coulometric oxidation of RuD2-Cl₂. In the case of cis-RuD¹₂Cl₂⁺, the complex has been isolated in the pure state as the perchlorate salt ($\mu_{eff} = 1.90 \ \mu_{B}$; $\Lambda =$ 132 Ω^{-1} cm² M⁻¹ in acetonitrile solution). The electronic and EPR spectra of the complexes are given in Figure 2 and the data are given in Tables 1 and 2. As in the case of RuDACl2,

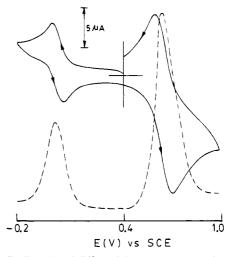

Figure 5. Cyclic (-) and differential pulse (- -) voltammograms of the product resulting from the completed reaction of cis-RuD22Cl2+ with water in MeCN solution. The two responses (current heights 2:1) correspond to the couples cis-RuD22Cl2+-cis-RuD22Cl2 (higher potential) and cis-RuD²A²Cl₂-cis-RuD²A²Cl₂- (lower potential).

a low-energy ligand field band (t₂ splitting) is observed in the expected region (Figure 2, Table 2).

The RuD₂Cl₂⁺ complexes are stable in dry solvents, and their cyclic voltammograms (initial scan cathodic) are superposable on those of the corresponding RuD2Cl2 complexes (initial scan anodic), implying that the redox process is stereoretentive, as implied in eq 2.

Reaction with Water. Rate and Activation Parameters. In wet solutions, RuD₂Cl₂⁺ reacts spontaneously and quantitatively as in eq 4. The 1:2 ratio of RuDACl₂ and RuD₂Cl₂ at

$$3cis/trans$$
-RuD₂Cl₂⁺ + H₂O \rightarrow
 $cis/trans$ -RuDACl₂ + $2cis/trans$ -RuD₂Cl₂ + $3H^+$ (4)

completion of the reaction is in accord with the heights of the distinctive voltammetric peaks (couples of eqs 2 and 3) of the two species and spectral intensities (see below) thereof. The voltammetric results for a representative case, viz cis-RuD²₂-Cl₂⁺, is depicted in Figure 5. The measurement was carried out by dissolving in acetonitrile the dry residue left after complete removal of solvent and water at the end of the reaction. In essence, the reaction of eq 4 is a disproportionation in which the ligand is oxidized at the expense of the metal which becomes reduced. The amide oxygen originates from water. The transformation proceeds unhindered in oxygen-free environ-

The rate of the reaction of eq 4 is amenable to spectrophotometric examination in 1:6 dichloromethane-acetonitrile solution containing measured amounts of water. The case of trans-RuD²₂Cl₂⁺ is particularly convenient for the study, and details will be presented for this case. The largest changes occur near 700 nm due to the growth of the MLCT band (Table 2) of trans-RuD²₂Cl₂. The other two species have low absorptions in this region. At the end of the reaction, the absorption at 700 nm corresponds to the conversion of two-thirds of the total ruthenium into trans-RuD²₂Cl₂ as required by eq 4.

Rates were monitored at 700 nm using the changes in absorption, A_t , as a function of time, t. In the presence of excess water (pseudo-first-order conditions) the rate of the transformation is found to be proportional to the concentration of trans- $RuD_2^2Cl_2^+$, eq 5. Further, the observed rate constant k_{obs} varies

$$rate = k_{obs}[trans-RuD_{2}^{2}Cl_{2}^{+}]$$

$$k_{\text{obs}} = k[H_2O] \tag{6}$$

$$rate = k[trans-RuD^{2},Cl_{2}^{+}][H_{2}O]$$
 (7)

linearly with the concentration of water according to eq 6. Thus the formation of trans-RuD²A²Cl₂ from trans-RuD²₂Cl₂⁺ and water follows the second-order rate law of eq 7. Variable-temperature rate constants and the derived activation parameters are listed in Table 6. The large decrease of entropy (\sim 30 eu) in the activation process is suggestive of strong "association" between water and trans-RuD²₂Cl₂⁺ in the rate-determining step (rds).

A Reaction Model. The addition of water to the imine function leading to an α -hydroxy amine moiety (>C=N- \rightarrow >C(OH)NH) is a documented pathway to Schiff base hydrolysis (to >C=O and -NH₂). If In some instances, the product of addition of water or alcohol has been found to be a stable entity. A plausible rationale for the above-noted close association between the ruthenium(III) α -diimine complex and water is actual addition as expressed by general reaction of eq. 8. The crucial requirement is that the adduct 6 (or NH-

$$RuD_2Cl_2^+ + H_2O \xrightarrow{rds} \mathbf{6}$$
 (8)

deprotonated version thereof) must undergo rapid oxidation before the possible hydrolysis-related complications could set in. Two electrons are to be transferred and a plausible route is induced electron transfer: ${}^{3.16}6 \rightarrow 7$ (oxidative radical formation), $7 \rightarrow 8$ (internal redox and proton loss), and $8 \rightarrow 3$ (metal oxidation), eqs 9-11, where $RuD_2Cl_2^+$ acts as the external

$$RuD_2Cl_2^+ + 6 \rightarrow 7 + 2H^+ + RuD_2Cl_2$$
 (9)

$$7 \rightarrow 8 + H^{+} \tag{10}$$

$$RuD_{2}Cl_{2}^{+} + 8 \rightarrow 3 + RuD_{2}Cl_{2}$$
 (11)

oxidant. The reduction potentials are right for the reaction, and there is no kinetic barrier either. In the prescription of Scheme 1, aqueous cerium(IV) (or hydrogen peroxide) acts as the external oxidant and the whole of RuD₂Cl₂ is thus converted to RuDACl₂ via RuD₂Cl₂⁺ according to the stoichiometry stated in eqs 12 and 13.

$$RuD_2Cl_2 + Ce^{4+} \rightarrow RuD_2Cl_2^+ + Ce^{3+}$$
 (12)

$$RuD_2Cl_2^+ + H_2O + 2Ce^{4+} \rightarrow RuDACl_2 + 2Ce^{3+} + 3H^+$$
(13)

[&]quot;Least-squares deviations are given in parentheses.

The oxidation of $Re^{III}(pD)(OPPh_3)Cl_3$, **9**, to $Re^{IV}(pA)(OPPh_3)Cl_3$, **10**, where pD is pyridine-2-carboxaldimine (as in **1**) and pA is the corresponding amide (deprotonated) has been briefly reported from this laboratory.\(^1\) Here the reactive intermediate is $Re^{IV}(pD)(OPPh_3)Cl_3^+$, **9**+, which disproportionates in water, eq 14, following the rate law of eq 15 (k = 1.92 \times 10⁻⁴ M⁻¹ s⁻¹ at 298 K).\(^6\) In the presence of an external oxidant (Ce^{4+} or H_2O_2), the conversion of **9** to **10** goes to completion.

$$39^{+} + H_{2}O \rightarrow 10 + 29 + 3H^{+}$$
 (14)

$$rate = k[9^+][H,O]$$
 (15)

Thus the two otherwise very different systems RuD_2Cl_2 and $Re(pD)(OPPh_3)Cl_3$ act as close analogs as far as the aldimine \rightarrow amide transformation is concerned. At this stage, the following general traits appear to be crucial. (i) The coordinated metal atom should have two easily accessible oxidation states related by facile transfer of one electron $(Ru^{2+}, Ru^{3+}; Re^{3+}, Re^{4+})$. (ii) The higher oxidation state should have sufficient polarizing effect on the aldimine function to make the carbon site electrophilic enough to promote water binding. (iii) The water adduct should have the ability to undergo rapid electron transfer at ligand and metal sites. These provide a working base for expanding the scope of the aldimine \rightarrow amide reaction to newer systems.

Concluding Remarks. The main results of this work will now be summarized. The isomeric $Ru^{II}D_2Cl_2$ chelates are shown to be excellent substrates for aldimine \rightarrow amide transformation, which is found to proceed stereoretentively, affording $Ru^{III}DACl_2$.

The trends of ruthenium(III)—ruthenium(II) reduction potentials (cis > trans) and of transition energies (trans > cis) within the split t_2 shells are consistent with the isomeric geometries of RuDACl₂. The same applies to RuIIID₂Cl₂+, the product of one-electron oxidation of RuD₂Cl₂ in dry solvents. The metal reduction potentials of RuDACl₂ are ~ 0.5 V lower than those of RuD₂Cl₂. Significantly, the Ru-N(amide) distance is ~ 0.1 Å shorter than the Ru-N(imine) distance in cis-RuD²A²Cl₂.

The transformation $RuD_2Cl_2 \rightarrow RuDACl_2$ occurs via $RuD_2-Cl_2^+$, which reacts with water, affording the amide complex, the entropy of activation being strongly negative. It is proposed that water adds to an imine function and the resultant α -hydroxy amine function is rapidly oxidized to amide by an induced electron transfer route. Our search for newer examples of the

aldimine → amide reaction is continuing with the objective of augmenting and generalizing the ideas presented in this work.

Experimental Section

Materials. Hydrated ruthenium trichloride (Arora Matthey, Calcutta) was purified by repeated treatment with concentrated hydrochloric acid.¹⁷ The complex Ru(Me₂SO)₄Cl₂¹⁸ and the glyoxaldiimines¹⁹ were prepared by reported methods. The purification and drying of dichloromethane and acetonitrile for electrochemical and spectral work were done as before.²⁰ All other chemicals and solvents were of reagent grade and were used without further purification.

Physical Measurements. Electronic spectra were recorded with a Hitachi 330 spectrophotometer fitted with a thermostated cell compartment. Infrared spectra (4000-300 cm⁻¹) were taken on a Perkin-Elmer 783 spectrophotometer, and X-band EPR spectra were recorded on a Varian E-109C spectrometer fitted with a quartz Dewar flask. The spectra were calibrated with respect to DPPH (g = 2.0037). Electrochemical measurements (cyclic voltammetry, coulometry, and differential pulse voltammetry) were done by using a PAR Model 370-4 electrochemistry system as described elsewhere.²¹ All experiments were performed at a platinum working electrode under dinitrogen atmosphere, the supporting electrolyte being tetraethylammonium perchlorate (TEAP). The potentials are referred to the saturated calomel electrode (SCE) and are uncorrected for junction contribution. Magnetic susceptibilities were measured on a PAR-155 vibrating-sample magnetometer. Solution (10⁻³ M) electrical conductivity was measured by using a Philips PR 9500 bridge. Microanalyses (C,H,N) were done by using a Perkin-Elmer 240C elemental analyzer.

Synthesis of RuD₂Cl₂. trans-Dichlorobis(N_rN' -dicyclohexylgly-oxal diimine)ruthenium(II), trans-RuD¹₂Cl₂. The complex Ru(Me₂-SO)₄Cl₂ (100 mg, 0.20 mmol) was suspended in 20 mL of ethanol, and D¹ (100 mg, 0.45 mmol) was added. The mixture was kept warm at 40 °C for 15 min. The resulting blue solution was evaporated to dryness under reduced pressure. The solid mass thus obtained was dissolved in 5 mL of dichloromethane, and the solution was subjected to chromatography on a silica gel column (20 × 1 cm; 60–120 mesh, BDH). On elution with benzene—acetonitrile (9:1), a deep blue band of the required complex moved rapidly. Upon slow evaporation of the eluent, the complex was obtained as shining blue microcrystals. Yield: 75%. Anal. Calcd for trans-RuD¹₂Cl₂, RuC₂₈H₄₈N₄Cl₂: C, 54.90; H, 7.84; N, 9.15. Found: C, 54.65; H, 7.80; N, 9.13.

cis-Dichlorobis(N,N'-dicyclohexylglyoxal diimine)ruthenium(II), cis-RuD¹₂Cl₂. The trans isomer (100 mg, 0.16 mmol) was dissolved in 20 mL of ethanol and the solution refluxed for 30 min to give a dark pink solution which afforded the crystalline cis complex in quantitative yield upon solvent evaporation.

The complex was also synthesized by refluxing a 1:2 mixture of $Ru(Me_2SO)_4Cl_2$ and D^1 in ethanol for 30 min. The resulting pink solution was evaporated to dryness under reduced pressure, and the solid mass thus obtained was dissolved in 5 mL of dichloromethane. The solution was subjected to chromatography on a silica gel column $(20 \times 1 \text{ cm}; 60-120 \text{ mesh}, BDH)$. On elution with benzene—acetonitrile (7:3), a dark pink band moved rapidly and was collected. The required complex was obtained from the eluent as shining dark-colored crystals by slow evaporation. Yield: 85%. Anal. Calcd for cis-RuD 1 ₂Cl $_2$, RuC $_2$ ₈H $_4$ ₈N $_4$ Cl $_2$: C, 54.90; H, 7.84; N, 9.15. Found: C, 54.62; H, 7.78; N, 9.12.

Single crystals of composition cis-RuD¹₂Cl₂·PhMe were obtained by the slow diffusion of toluene into a dichloromethane solution of cis-

 $RuD_{2}^{1}Cl_{2}$. Anal. Calcd for cis- $RuD_{2}^{1}Cl_{2}$ -PhMe, $RuC_{35}H_{56}N_{4}Cl_{2}$: C, 59.66; H, 7.95; N, 7.95. Found: C, 59.60; H, 7.92; N, 7.91.

trans-Dichlorobis(N_*N' -di-p-tolylglyoxal diimine)ruthenium(II), trans-RuD²2Cl₂. The complex Ru(Me₂SO)₄Cl₂ (100 mg, 0.20 mmol) was suspended in 20 mL of ethanol, and to the suspension was added D² (100 mg, 0.42 mmol). The mixture was refluxed for 30 min and then cooled. A green microcrystalline solid precipitated, which was collected by filtration, washed thoroughly with ethanol, and finally dried in vacuo over P₄O₁0. Yield: 85%. Anal. Calcd for trans-RuD²2Cl₂, RuC₃2H₃2N₄Cl₂: C, 59.63; H, 4.97; N, 8.69. Found: C, 59.58; H, 4.93; N, 8.62.

cis-Dichlorobis(N,N'-di-p-tolylglyoxal diimine)ruthenium(II), cis-RuD²₂Cl₂. This complex was prepared by boiling the trans isomer in diglyme as reported.⁴ Anal. Calcd for cis-RuD²₂Cl₂, RuC₃₂H₃₂N₄Cl₂: C, 59.63; H, 4.97; N, 8.69. Found: C, 59.60; H, 4.90; N, 8.60.

Conversion of RuD₂Cl₂ to RuD₄Cl₂ by Using Cerium(IV) as Oxidant. One representative case will be described in detail.

 $\it cis$ -Dichloro(N-cyclohexyl(cyclohexylimino)acetamidato)(N,N'-dicyclohexylglyoxal diimine)ruthenium(III), $\it cis$ -RuD¹A¹Cl2. To a solution of 100 mg (0.16 mmol) of $\it cis$ -RuD¹_2Cl2 in 30 mL of dichloromethane—acetonitrile (1:6) was added 230 mg (0.36 mmol) (NH₄)₄Ce(SO₄)₄·2H₂O dissolved in 20 mL of water. The mixture was stirred at room temperature for 15 h. The reaction mixture was then filtered and the filtrate evaporated to dryness under reduced pressure. The reddish brown solid product thus obtained was dried in vacuo over P₄O₁₀. Yield: 88%.

The complexes *trans*-RuD¹A¹Cl₂, *cis*-RuD²A²Cl₂, and *trans*-RuD²A²-Cl₂ were synthesized similarly in 75–85% yields from *trans*-RuD¹₂-Cl₂, *cis*-RuD²₂Cl₂, and *trans*-RuD²₂Cl₂, respectively. After addition of oxidant, the stirring times in these cases were respectively 10, 2, and 10 h.

Anal. Calcd for *cis*-RuD¹A¹Cl₂, RuC₂₈H₄₇N₄OCl₂: C, 53.59; H, 7.49; N, 8.93. Found: C, 53.54; H, 7.45; N, 8.90. Found for *trans*-RuD¹A¹Cl₂: C, 53.55; H, 7.46; N, 8.91. Anal. Calcd for *cis*-RuD²A²Cl₂, RuC₃₂H₃₁N₄OCl₂: C, 58.27; H, 4.70; N, 8.50. Found: C, 58.22; H, 4.67; N, 8.46. Found for *trans*-RuD²A²Cl₂: C, 58.20; H, 4.62; N, 8.46.

Single crystals of composition *cis*-RuD¹A¹Cl₂·CH₂Cl₂ were grown from the slow diffusion of hexane into a dichloromethane solution of *cis*-RuD¹A¹Cl₂. Anal. Calcd for *cis*-RuD¹A¹Cl₂·CH₂Cl₂, RuC₂₉H₄₉N₄OCl₄: C, 48.89; H, 6.88; N, 7.87. Found: C, 48.85; H, 6.83; N, 7.85.

Conversion of RuD₂Cl₂ to RuDACl₂ by Using Hydrogen Peroxide as Oxidant. On representative case will be described.

trans-Dichloro(N-cyclohexyl(cyclohexylimino)acetamidato)(N_1N' -dicyclohexylglyoxal diimine)ruthenium(III), trans-RuD¹A¹Cl₂. To a solution of 100 mg (0.16 mmol) of trans-RuD¹2Cl₂ in 30 mL of dichloromethane—acetonitrile (1:6) was added 0.5 mL of 30% H_2O_2 , and the mixture was stirred for 10 h. The resulting solution was evaporated to dryness under reduced pressure, and the dark brown solid product was washed thoroughly with water and dried in vacuo over P_4O_{10} . Yield: 78%.

The complex *trans*-RuD²A²Cl₂ can be similarly prepared from *trans*-RuD²₂Cl₂. Hydrogen peroxide can be used for preparing *cis*-RuDACl₂ species also, but the yields are poor. Anal. Calcd for *trans*-RuD¹A¹-Cl₂, RuC₂₈H₄₇N₄OCl₂: C, 53.59; H, 7.49; N, 8.93. Found: C, 53.55; H, 7.46; N, 8.91. Calcd for *trans*-RuD²A²Cl₂, RuC₃₂H₃₁N₄OCl₂: C, 58.27; H, 4.70; N, 8.50. Found: C, 58.22; H, 4.57; N, 8.46.

cis-Dichlorobis(N,N'-dicyclohexylglyoxal diimine)ruthenium(III) Perchlorate, cis-[RuD¹₂Cl₂]ClO₄. To a solution of 100 mg (0.16 mmol) of cis-RuD¹₂Cl₂ in 30 mL of dichloromethane—acetonitrile (1: 6) was added 115 mg (0.18 mmol) of (NH₄)₄Ce(SO₄)₄·2H₂O, dissolved in 5 mL of water. The mixture was stirred at room temperature for 5 min. The orange solution was then filtered, and to the filtrate was added a saturated aqueous sodium perchlorate solution (10 mL). An orange solid was obtained upon evaporation of the solvent. It was washed thoroughly with water and dried in vacuo over P₄O₁₀. Yield: 80%. The same product was also obtained by the coulometric oxidation of cis-RuD¹₂Cl₂ in dry 1:6 dichloromethane—acetonitrile (0.1 M in TEAP) at +0.80 V vs SCE. Solvent evaporation and repeated recrystallization from acetonitrile—benzene gave the pure product in

Kinetic Measurements. The trans isomer of RuD²₂Cl₂ was quantitatively oxidized to *trans*-RuD²₂Cl₂ via coulometry at +0.60 V versus SCE in a 1:6 mixture of scrupulously dry dichloromethane and acetonitrile (0.1 M in TEAP). Aliquots of this solution were diluted as required, and measured amounts of water were added using a calibrated microsyringe. The presence of acetonitrile in the solvent helped to keep the solution homogeneous after water addition.

The reaction was followed spectrophotometrically at 700 nm. The absorption, A_t , was digitally recorded as a function of time, t, and A_{∞} was measured (after 24 h) when the reaction was complete. Values of pseudo-first-order rate constants (k_{obs}) were obtained from the slopes of the highly linear plots of $-\ln(A_{\infty}-A_t)$ versus t. A minimum of 30 A_t-t data points were used in each calculation. Values of the second-order rate constants (k) were obtained from the slopes of the excellently linear plots of k_{obs} versus $[H_2O]$. The activation enthalpy and entropy parameters, ΔH^{\ddagger} and ΔS^{\ddagger} , were obtained from variable-temperature (7–25 °C) rates using the Eyring equation. All linear fittings and standard deviation calculations were made by the usual least-squares methods.²²

X-ray Structure Determination. Dimensions of prismatic crystals were $0.40 \times 0.28 \times 0.26 \text{ mm}^3$ for cis-RuD¹₂Cl₂·PhMe and $0.36 \times 0.27 \times 0.12 \text{ mm}^3$ for cis-RuD¹A¹Cl₂·CH₂Cl₂. Both the crystals were dark-colored, and unless otherwise stated, similar procedures were used for both

Cell parameters were determined by a least-squares fit of 30 machine-centered reflections ($2\theta=15-30^\circ$). Data were collected by the ω -scan technique in the range $3^\circ \le 2\theta \le 45^\circ$ on a Siemens R3m/V four-circle diffractometer with graphite-monochromated Mo K α radiation. Two check reflections monitored after each 98 reflections showed no significant intensity reduction in the case of cis-RuD¹₂Cl₂. PhMe (52 h of exposure), but for cis-RuD¹A¹Cl₂·CH₂Cl₂, the intensity decreased by 15% during data collection (56 h of exposure). The latter data were corrected for decay (the decay correction range on intensities being 0.8538-1.0000). All data were corrected for Lorentz-polarization and absorption. Of the 5113 (RuD¹₂Cl₂·CH₂Me: h=0, 16; h=0, 21; h=0, 16 and 5342 (RuD¹A¹Cl₂·CH₂Cl₂: h=0, 14; h=0, 33; h=015, 15) reflections collected, 4707 and 4821 were unique, of which 2986 and 2373 were respectively taken as observed (h=01) for

[&]quot; Equivalent isotropic U defined as one-third of the trace of the orthogonalized \mathbf{U}_{ii} tensor.

structure solution and refinement. For both structures, systematic absences corresponded to the space group $P2_1/c$.

The metal atoms were located from Patterson maps, and the rest of the non-hydrogen atoms emerged from successive Fourier syntheses. The structures were then refined by full-matrix least-squares procedures. All non-hydrogen atoms were refined anisotropically, and hydrogen atoms were added at calculated positions with fixed $U=0.08~\text{Å}^2$ in the final cycle of refinement. In cis-RuD¹A¹Cl₂·CH₂Cl₂, the solvent molecule was disordered. The highest residual were 0.29 and 0.58 e Å-3, respectively, for RuD¹₂Cl₂·PhMe and RuD¹A¹Cl₂·CH₂Cl₂. All calculations were done on a Micro VAX II computer using the SHELXTL-Plus program package.²⁴ Significant crystal data are listed in Table 7. Selected atomic coordinates and isotropic thermal parameters are collected in Tables 8 and 9.

Acknowledgment. Financial support received from the Department of Science and Technology, New Delhi, is gratefully acknowledged. Thanks are expressed to the Council of Scientific and Industrial Research, New Delhi, for providing Fellowship awards to A.P. and M.M.

Supplementary Material Available: For RuD¹₂Cl₂PhMe and RuD¹A¹Cl₂·CH₂Cl₂, tables of complete bond distances (Tables S1 and S5) and angles (Tables S2 and S6), anisotropic thermal parameters (Tables S3 and S7), hydrogen atom positional parameters (Tables S4 and S8), and atomic coordinates and equivalent isotropic displacement coefficients of non-hydrogen atoms (Tables S9 and S10) (12 pages). Ordering information is given on any current masthead page.
