Received February 16, 1999

The reaction of [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>S with equimolar amounts of SCl<sub>2</sub> and SO<sub>2</sub>Cl<sub>2</sub> produces S<sub>4</sub>N<sub>4</sub> in a good yield. The new chalcogen nitride 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> has been prepared in high yield by two different reactions: (a) from [(Me<sub>3</sub>-Si)<sub>2</sub>N]<sub>2</sub>S and SeCl<sub>4</sub> and (b) from [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>Se with equimolar amounts of SCl<sub>2</sub> and SO<sub>2</sub>Cl<sub>2</sub>. 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> has a cage structure similar to those of S<sub>4</sub>N<sub>4</sub> and Se<sub>4</sub>N<sub>4</sub>. The crystal structure is disordered with site occupation factors ca. 50% for selenium in each chalcogen atom position. The 12 eV EI mass spectrum shows Se<sub>2</sub>SN<sub>2</sub><sup>+</sup> as the fragment with highest mass. Both the <sup>14</sup>N and <sup>77</sup>Se NMR spectra show a single resonance (−238 and 1418 ppm, respectively). These data rule out the possibility that the crystalline sample is a solid solution of S<sub>4</sub>N<sub>4</sub> and Se<sub>4</sub>N<sub>4</sub> and imply the presence of 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>. This deduction was further verified by Raman spectroscopy and vibrational analysis.

### Introduction

Tetrasulfur tetranitride S<sub>4</sub>N<sub>4</sub> is a common starting material for the preparation of a wide variety of cyclic and acyclic sulfur–nitrogen species.<sup>2</sup> The crystal structure determinations<sup>3</sup> have established that the molecule exhibits a cage structure (1) with unusual bonding features that are still not completely understood.<sup>4</sup>

Two polymorphs are known for crystalline tetraselenium tetranitride Se<sub>4</sub>N<sub>4</sub><sup>6</sup> one of them being isostructural with S<sub>4</sub>N<sub>4</sub>.<sup>6b</sup> In both polymorphic forms, however, the molecule shows a cage

structure similar to S<sub>4</sub>N<sub>4</sub>. Though Se<sub>4</sub>N<sub>4</sub> is extremely unstable and therefore difficult to handle in large amounts, it has proven to be a convenient source for both neutral and ionic Se–N species.<sup>7</sup>

The catalytic vapor phase decomposition of S<sub>4</sub>N<sub>4</sub> produces cyclic S<sub>2</sub>N<sub>2</sub> that polymerizes spontaneously to polymeric sulfur nitride (SN)<sub>x</sub>.<sup>11</sup> It was discovered in 1970s that (SN)<sub>x</sub> has anisotropic semiconducting properties and that it becomes a superconductor below 0.33 K.<sup>12</sup> Other routes to produce polymeric sulfur nitride are also known.<sup>13</sup> The polymer (SeN)<sub>x</sub> and mixed chalcogen–nitrogen polymers are also expected to have interesting structural and electrical properties. Their preparation and characterization, however, have not been reported, probably because of the instability of the likely precursors.

In this paper we describe in detail convenient syntheses for S<sub>4</sub>N<sub>4</sub> and 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>.<sup>14</sup> They rely on the reagents [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>S and [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>Se, which are readily prepared<sup>15</sup> and can be used as a source of the NEN (E = S, Se) fragment. We have previously reported that the reaction of [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>Se and SeCl<sub>4</sub> provides a route to Se<sub>4</sub>N<sub>4</sub>.<sup>16</sup> We now find that treatment of [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>S with a mixture of SCl<sub>2</sub> and SO<sub>2</sub>Cl<sub>2</sub> produces S<sub>4</sub>N<sub>4</sub> in good yields. The analogous reactions involving [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>S and SeCl<sub>4</sub> or [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>Se with a mixture of SCl<sub>2</sub> and SO<sub>2</sub>Cl<sub>2</sub> result in the formation of 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>. This new hybrid chalcogen nitride has been identified by X-ray crystallography, Raman spectroscopy, NMR spectroscopy (<sup>77</sup>Se and <sup>14</sup>N), and mass spectroscopy.

## Experimental Section

**General.** All reactions were carried under an argon atmosphere. (Me<sub>3</sub>Si)<sub>2</sub>NH (Aldrich), *n*-butyllithium (2.5 M in hexanes, Aldrich), and selenium tetrachloride (SeCl<sub>4</sub>, E. Merck GmbH) were used without further purification. Sulfur dichloride (SCl<sub>2</sub>, Fluka Chemie AG) was distilled over PCl<sub>3</sub>, and sulfonyl chloride (SO<sub>2</sub>Cl<sub>2</sub>) was distilled over P<sub>4</sub>O<sub>10</sub> under an argon atmosphere. Se<sub>2</sub>Cl<sub>2</sub> was prepared as described by Fehér.<sup>17</sup> [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>S and [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>Se were prepared from (Me<sub>3</sub>Si)<sub>2</sub>NH by utilizing the methods of Wolmershäuser et al.<sup>15a</sup> and Roesky et al.,<sup>15b</sup> respectively. Both compounds were purified by distillation. Dichloromethane (E. Merck GmbH) and carbon disulfide (E. Merck GmbH) were dried by distillation under a nitrogen atmosphere over P<sub>4</sub>O<sub>10</sub> before use.

**Preparation of S<sub>4</sub>N<sub>4</sub>.** *Caution! Samples of S<sub>4</sub>N<sub>4</sub> may be explosive under the influence of heat or mechanical stress. The solid crystalline product should be handled with great care. The reaction should not be carried out in a large scale.*

[(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>S (0.352 g, 1.00 mmol) was dissolved in dichloromethane (10 mL), and a mixture of SCl<sub>2</sub> (0.103 g, 1.00 mmol), and SO<sub>2</sub>Cl<sub>2</sub> (0.135 g, 1.00 mmol) in dichloromethane (10 mL) was added dropwise at -78 °C. The reaction mixture was stirred overnight and allowed to warm slowly to room temperature. After the brown solution was filtered and the solvent removed by evaporation, an orange-brown powder was obtained. The crude product was recrystallized from toluene to give pale orange crystals. The total yield of S<sub>4</sub>N<sub>4</sub> was 75% (0.138 g, 0.75 mmol).<sup>18</sup> The <sup>14</sup>N NMR spectrum showed only one resonance at -256 ppm.<sup>19</sup> IR: 928 vs, 768 w, 727 m, 700 vs, 630 w, 553 vs, 548 vs, 529 w. Raman: 763 vw, 719 m, 559 s, 519 w, 347 m, 215 vs, 197 vs.<sup>21</sup>

**Preparation of Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>.** *Caution! Dry Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> is explosive under the influence of heat or mechanical stress. The product should be stored*

and handled under hydrocarbon solvents, and its preparation limited to amounts of <1.0 g.

**Reaction a.** A solution of [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>S (0.352 g, 1 mmol) in CS<sub>2</sub> (10 mL) was added to a suspension of SeCl<sub>4</sub> (0.221 g, 1 mmol) in CS<sub>2</sub> (20 mL) at -70 °C. The reaction mixture was stirred overnight and allowed to warm slowly to room temperature to give a dark red, slightly soluble precipitate. The precipitate was removed by filtration and washed three times with CH<sub>2</sub>Cl<sub>2</sub>. The yield was 0.105 g (76% based on Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>).<sup>23</sup>

**Reaction b.** Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> was also prepared by treating 10 mL of a CH<sub>2</sub>Cl<sub>2</sub> solution of [(Me<sub>3</sub>Si)<sub>2</sub>N]<sub>2</sub>Se (0.400 g, 1 mmol) with 10 mL of a CH<sub>2</sub>Cl<sub>2</sub> solution containing 0.103 g (1 mmol) SCl<sub>2</sub> and 0.135 g (1 mmol) SO<sub>2</sub>Cl<sub>2</sub> at -70 °C. The reaction mixture was stirred overnight and the dark red slightly soluble precipitate was filtered and washed three times with CH<sub>2</sub>Cl<sub>2</sub>. The yield was 0.10 g (72% based on Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>).<sup>23</sup>

Single crystals of Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> were obtained by carrying out reaction **b** at room temperature. The solution was allowed to stand for 3 days during which orange, almost spherical, crystals were formed. These crystals were used for the mass spectroscopic, vibrational spectroscopic, <sup>14</sup>N and <sup>77</sup>Se NMR spectroscopic, and crystallographic identification of the product, as discussed below.

**Spectroscopy.** The <sup>14</sup>N and <sup>77</sup>Se NMR spectra were recorded on a Bruker DPX 400 spectrometer operating at 28.911 and 76.410 MHz, respectively. The spectral widths were 10.42 and 114.94 kHz, yielding the respective resolutions of 1.24 and 1.75 Hz/data point. The <sup>14</sup>N pulse width was 5.70 μs, and that for <sup>77</sup>Se 6.70 μs, corresponding to nuclear tip angles of 21 and 46°, respectively. The <sup>14</sup>N accumulations contained ca. 100 000 transients, and those for selenium contained ca. 35 000 transients. D<sub>2</sub>O was used as an external <sup>2</sup>H lock and CH<sub>3</sub>NO<sub>2</sub> and a saturated solution of SeO<sub>2</sub> as external references. The <sup>14</sup>N chemical shifts are reported relative to the external reference, and the <sup>77</sup>Se chemical shifts relative to neat Me<sub>2</sub>Se [ $\delta(\text{Me}_2\text{Se}) = \delta(\text{SeO}_2) + 1302.6$ ].

MS-EI mass spectra were recorded by using a Kratos MS 80 spectrometer at 12 eV of electron energy. The Raman spectra were obtained from solid samples at ca. -100 °C by using a Bruker IFS-66 spectrometer equipped with a FRA-16 Raman unit and a Nd:YAG laser.

Fundamental vibrations were calculated for Se<sub>4</sub>N<sub>4</sub> and 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> by using a general valence force-field approach.<sup>24</sup> The *F* matrix of Se<sub>4</sub>N<sub>4</sub> contained six diagonal force constants and nine off-diagonal interaction force constants. The analogous force field for 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> contained 18 force constants. The molecular geometry for Se<sub>4</sub>N<sub>4</sub> was taken from the crystal structure determination<sup>25</sup> and that for 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> was estimated on the basis of the structural data taken from S<sub>4</sub>N<sub>4</sub> and Se<sub>4</sub>N<sub>4</sub>.<sup>3,6</sup> The initial values of the force constants were estimated from those of S<sub>4</sub>N<sub>4</sub><sup>22a</sup> and SeS<sub>3</sub>N<sub>2</sub>.<sup>26</sup> They were refined by adjusting the observed frequencies to the calculated values until no further change was observed.

**X-ray Crystallography.** Crystal data and details of the structure determination are given in Table 1. Diffraction data were collected on a Siemens *R3m* diffractometer at 293 K using graphite monochromated Mo K $\alpha$  radiation ( $\lambda = 0.71073$  Å). The unit cell parameters were determined by the least-squares refinement of 25 automatically centered reflections. Two reference reflections were used to monitor the stability of the crystal. Their intensities were recorded periodically after each

<sup>b</sup>  $w = [\sigma^2(F_o^2) + (0.0792P)^2]^{-1}$ , where  $P = \{\max(F_o^2, 0) + 2F_c^2\}/3$ .

batch of 98 data. The decay of the crystal appeared to be negligible during the data collection. The total number of 1031 independent reflections were collected in the 2 $\theta$  range 6–50° of which 649 were considered observed [*I* > 2 $\sigma$ (*I*)]. Their net intensities were corrected for Lorentz and polarization effects.

Since the crystal was isostructural with  $\text{S}_4\text{N}_4$ <sup>3</sup> and  $\beta$ - $\text{Se}_4\text{N}_4$ ,<sup>6b</sup> the initial atomic coordinates were taken from the crystal structure determination of  $\text{S}_4\text{N}_4$ .<sup>3</sup> The structure was refined using SHELXL-97.<sup>27</sup> It became apparent early in the refinement that the chalcogen atom positions were disordered with sulfur and selenium statistically distributed over the atomic sites. Therefore, the site occupation factors of sulfur and selenium were refined along the positional and thermal parameters. Because of the correlation between the thermal parameters and the occupation factors, the following constraints need to be applied:

$$sof_{\text{Se}(i)} + sof_{\text{S}(i)} = 1$$

$$U_{\text{Se}(i)} = U_{\text{S}(i)}$$

where  $sof_{\text{Se}(i)}$ ,  $sof_{\text{S}(i)}$ ,  $U_{\text{Se}(i)}$ , and  $U_{\text{S}(i)}$  are the site occupation factors and the thermal parameters (isotropic or anisotropic) of selenium and sulfur at the *i*th atomic position. The estimation of the electron density, and thus the site occupation factors of sulfur and selenium at the given chalcogen atom position necessitates the constraining of the corresponding sulfur and selenium atoms in the same position. The scattering factors for the neutral atoms were those incorporated with the programs.

Fractional coordinates, isotropic thermal parameters, anisotropic thermal parameters, and all bond parameters are available as Supporting Information.

## Results and Discussion

**Preparation of  $\text{S}_4\text{N}_4$ .** Tetrasulfur tetranitride can conveniently be prepared in good yields by the reaction of  $[(\text{Me}_3\text{Si})_2\text{N}]_2\text{S}$  with  $\text{SCl}_2$  and  $\text{SO}_2\text{Cl}_2$  in  $\text{CH}_2\text{Cl}_2$ :

Purification by recrystallization from toluene yielded pale orange crystals that were identified as  $\text{S}_4\text{N}_4$  by <sup>14</sup>N NMR, IR, and

**Figure 1.** Molecular structure of 1,5- $\text{Se}_2\text{S}_2\text{N}_4$ . Thermal ellipsoids are drawn at 50% probability level. The refined site occupation factors [ $sof_{\text{Se}(i)}$ ] in disordered chalcogen atom positions [ $E(i)$ ] are indicated in the figure ( $sof_{\text{S}(i)} = 1 - sof_{\text{Se}(i)}$ ).

Raman spectroscopy. The <sup>14</sup>N NMR spectrum showed only one resonance at -256 ppm.<sup>19</sup> Both IR and Raman spectra of  $\text{S}_4\text{N}_4$  are in good agreement with those reported earlier.<sup>22</sup>

$\text{S}_4\text{N}_4$  has traditionally been prepared by the treatment of  $\text{S}_2\text{Cl}_2$  with  $\text{Cl}_2$  gas in  $\text{CCl}_4$  followed by the reaction of the product with  $\text{NH}_3$  gas.<sup>28</sup> An aqueous workup procedure is necessary to remove  $\text{NH}_4\text{Cl}$ .<sup>29</sup> The reduction of various N–S–Cl compounds also leads to  $\text{S}_4\text{N}_4$ .<sup>31,32</sup> The synthesis described in this work (see eq 1) provides an attractive route to good yields of  $\text{S}_4\text{N}_4$ , which utilizes easily prepared starting materials, avoids the use of gaseous reactants, and employs a simple purification procedure.

**Preparation, Crystal Structure, and Spectroscopic Characterization of  $\text{Se}_2\text{S}_2\text{N}_4$ .** The reaction of  $[(\text{Me}_3\text{Si})_2\text{N}]_2\text{S}$  with  $\text{SeCl}_4$  in  $\text{CH}_2\text{Cl}_2$  produces  $\text{Se}_2\text{S}_2\text{N}_4$  as shown in eq 2.

The same compound can also be obtained by the reaction of  $[(\text{Me}_3\text{Si})_2\text{N}]_2\text{Se}$  with  $\text{SCl}_2$  and  $\text{SO}_2\text{Cl}_2$  in  $\text{CH}_2\text{Cl}_2$  (eq 3):

The product was obtained as dark brown-red powder, which was almost insoluble in organic solvents. Both reactions produce impure  $\text{Se}_2\text{S}_2\text{N}_4$  in good yields (ca. 75%). The elemental analysis of the solid product from both reactions indicates a mixture containing  $\text{Se}_2\text{S}_2\text{N}_4$  (91%) and Se (9%).<sup>23</sup>

The molecular structure of  $\text{Se}_2\text{S}_2\text{N}_4$  with the atomic numbering scheme is shown in Figure 1. The molecule has a cage structure similar to those of  $\text{S}_4\text{N}_4$ <sup>3</sup> and  $\text{Se}_4\text{N}_4$ .<sup>6</sup> The refined site occupation factors of selenium in all chalcogen-atom positions are near 50%. Consequently, all bond lengths [1.75(1)–1.80(1) Å] show intermediate values between those of  $\text{S}_4\text{N}_4$

<sup>a</sup> The data are taken from ref 22a. <sup>b</sup> The observed vibrations are based on the Raman spectra except where otherwise indicated. <sup>c</sup> The assignment is based on the most significant contributions (>10%) in the potential energy distribution. <sup>d</sup> References 22c and 36. <sup>e</sup> IR data.<sup>36</sup>

and  $\text{Se}_4\text{N}_4$  and reflect only the composition of the atomic positions (see Supporting Information). This is well exemplified by the transannular chalcogen–chalcogen contacts. In the present structure the two distances are 2.700(3) and 2.705(3) Å (see Figure 1) that fall between the  $\text{S}\cdots\text{S}$  distances (2.597 and 2.601 Å) found in  $\text{S}_4\text{N}_4^{3c}$  and the  $\text{Se}\cdots\text{Se}$  distances (2.740–2.742 Å) found in  $\alpha\text{-Se}_4\text{N}_4^{6a}$  and  $\beta\text{-Se}_4\text{N}_4^{6b,33}$ .

The observed disorder in the chalcogen atom sites indicates that either the lattice contains  $\text{Se}_2\text{S}_2\text{N}_4$  molecules that can assume different orientations, or that the crystalline phase is in fact a solid solution containing 50% of both  $\text{S}_4\text{N}_4$  and  $\text{Se}_4\text{N}_4$ . From the crystal structure determination alone it is not possible to distinguish between these two alternatives.

The 12 eV mass spectrum is shown in Figure 2. The fragment with the highest mass is  $\text{Se}_2\text{SN}_2^+$ . The observed and calculated isotopic distributions are in excellent agreement with each other (see Supporting Information). The fragmentation pattern implied by Figure 2 is also consistent with the molecular composition  $\text{Se}_2\text{S}_2\text{N}_4$ . The appearance of an  $\text{Se}_2\text{SN}_2^+$  fragment in the mass spectrum rules out the possibility that the crystalline sample is

**Figure 2.** 12 eV EI mass spectrum of  $\text{Se}_2\text{S}_2\text{N}_4$ .

a solid solution of  $\text{S}_4\text{N}_4$  and  $\text{Se}_4\text{N}_4$ . Furthermore, the mass spectrum shows no evidence of the parent peaks for  $\text{S}_4\text{N}_4$  and  $\text{Se}_4\text{N}_4$ .

The  $^{14}\text{N}$  and  $^{77}\text{Se}$  NMR spectra are recorded in  $\text{CS}_2$ . The  $^{14}\text{N}$  NMR spectrum shows a single resonance at  $-238$  ppm. This value is reasonable for  $\text{Se}_2\text{S}_2\text{N}_4$  when compared to  $-256$  ppm observed for  $\text{S}_4\text{N}_4$ .<sup>19</sup> The  $^{77}\text{Se}$  NMR spectrum also exhibits a

(33) The intensity data collections of  $\text{S}_4\text{N}_4^{3c}$  and  $\text{Se}_4\text{N}_4^6$  were carried out at  $-120$  °C, while the present structure has been determined at room temperature. The internuclear distances are therefore not exactly comparable.

**Figure 3.** The (a) 1,5- and (b) 1,3-isomers of Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>**Figure 4.** Raman spectrum of Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> recorded at ca. -100 °C. The signals marked with an asterisk are due to Se<sub>8</sub>.<sup>41</sup>

single resonance at 1418 ppm. The <sup>77</sup>Se chemical shift of tetraselenium tetranitride has not been recorded owing to the insolubility of the binary material.

The appearance of only one resonance in the <sup>14</sup>N NMR spectrum indicates that all nitrogen atoms are equivalent implying the existence of 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> rather than that of 1,3-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> in the sample solution (see Figure 3).<sup>34</sup> In the case of the 1,3-isomer three resonances at the intensity ratio of 1:2:1 are expected in the <sup>14</sup>N NMR spectrum. Both isomers should exhibit only one <sup>77</sup>Se resonance. The two preparative methods also imply the formation of 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>. The formation of 1,3-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> seems less likely, since it would require extensive rearrangement of the atoms and bonds during the reaction.<sup>35</sup>

Vibrational analysis provides further verification for the identity of the 1,5-isomer of Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>. The Raman spectrum is shown in Figure 4. The molecule belongs to the point group C<sub>2v</sub> and therefore all 18 fundamental vibrations (6a<sub>1</sub>, 4a<sub>2</sub>, 4b<sub>1</sub>, 4b<sub>2</sub>) are both Raman and IR active. The assignment of the spectrum has been carried out by calculating the fundamental vibrations for 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> using the general valence force field approach.<sup>24</sup> These calculations yield a good agreement with the observed Raman lines (see Table 2). The reliability of the assignment can be assessed by comparing it with the assignments for S<sub>4</sub>N<sub>4</sub> and Se<sub>4</sub>N<sub>4</sub>.

Both tetrasulfur tetranitride and tetraselenium tetranitride belong to the point group D<sub>2d</sub> and show twelve Raman active vibrations (3a<sub>1</sub>, 2b<sub>1</sub>, 3b<sub>2</sub>, and 4e) and seven IR active vibrations (3b<sub>2</sub> and 4e). The two a<sub>2</sub> modes are inactive. Steudel<sup>22a</sup> has performed an extensive normal coordinate treatment for tetrasulfur tetranitride with a modified Urey–Bradley force field. To date, these calculations yield the most reliable assignment for both Raman and IR spectra of S<sub>4</sub>N<sub>4</sub>. Our present general valence force field calculations for Se<sub>4</sub>N<sub>4</sub> produce an assignment with very similar potential energy distribution for all corresponding fundamental vibrations (see Table 2).

The assignment of the Raman spectrum of 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> is consistent with those made for both S<sub>4</sub>N<sub>4</sub> and Se<sub>4</sub>N<sub>4</sub>. When the symmetry is lowered from D<sub>2d</sub> to C<sub>2v</sub> the symmetry modes transform as follows: a<sub>1</sub> → a<sub>1</sub>, a<sub>2</sub> → a<sub>2</sub>, b<sub>1</sub> → a<sub>2</sub>, b<sub>2</sub> → a<sub>1</sub>, and e → b<sub>1</sub> + b<sub>2</sub>. This leads to the correlation between the fundamental vibrations of S<sub>4</sub>N<sub>4</sub>, 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>, and Se<sub>4</sub>N<sub>4</sub> shown in Table 2. The potential energy distribution in each group of correlated vibrations is rather similar in all three molecules and indicates that the assignments of the vibrational spectra of the three species are consistent with each other. The force field calculations also yield reasonable force constants for 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> and Se<sub>4</sub>N<sub>4</sub>. This is demonstrated in Table 3 by comparison of the stretching force constants of the present molecules with those of the related compounds.

## Conclusions

The new chalcogen nitride Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> has been prepared in good yields by two methods. The crystal structure and spectroscopic (<sup>14</sup>N and <sup>77</sup>Se NMR, mass, and Raman) data are consistent with the formation of the 1,5-isomer, which is a potential precursor, via thermolysis, of the four-membered ring SeSN<sub>2</sub> and, hence, the mixed chalcogen nitride polymer (SeSN)<sub>x</sub>.

IC9901791

(34) In principle the <sup>77</sup>Se and <sup>14</sup>N chemical shifts could also be assigned to Se<sub>4</sub>N<sub>4</sub>, but that would necessitate the appearance of the <sup>14</sup>N resonance at -256 ppm due to S<sub>4</sub>N<sub>4</sub> in the spectrum.

(35) The reaction 2 forms the cyclic eight-atom molecule from two NSN and two Se fragments and the reaction 3 from two NSeN and two S fragments. Therefore, in both cases 1,5-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub> should be formed rather than 1,3-Se<sub>2</sub>S<sub>2</sub>N<sub>4</sub>.
