Received January 11, 2005

Treatment of *trans*-[PtCl₄(RCN)₂] (R = Me, Et, Ph, NEt₂) with 2 equiv of the amidine PhC(=NH)NHPH in a suspension of MeCN (R = Me), CHCl₃ (R = Et, Ph), or in CHCl₃ solution (R = NEt₂) results in the formation of the imidoamidine complexes *trans*-[PtCl₄{NH=C(R)N=C(Ph)NHPH}₂] (**1–4**) isolated in good yields (66–84%). The reaction of soluble complexes **3** and **4** with 2 equiv of Ph₃P=CHCO₂Me in CH₂Cl₂ (40 °C, 5 h) leads to dehydrochlorination resulting in a chelate ring closure to furnish the platinum(IV) chelates [PtCl₂{NH=C(R)NC(Ph)=NPh}₂] (R = Ph, **5**; R = NEt₂, **6**), accordingly, and the phosphonium salt [Ph₃PCH₂CO₂Me]Cl. Treatment of **5** with 3 equiv of Ph₃P=CHCO₂Me at 50 °C for 5 d resulted in only a 30% conversion to the corresponding Pt(II) complex [Pt{NH=C(NEt₂)NC(Ph)=NPh}₂] (**15**). The reduction can be achieved within several minutes, when Ph₂PCH₂CH₂PPh₂ in CDCl₃ is used. When the platinum(II) complex *trans*-[PtCl₂(RCN)₂] is reacted with 2 equiv of the amidine, the imidoamidinato complexes [PtCl(RCN){NH=C(R)NC(Ph)=MHPH}] (**8–11**) and [PhC(=NH)NHPH]·HCl (**7**) are formed. The reaction of *trans*-[PtCl₂(RCN)₂] with 4 equiv of the amidine under a prolonged reaction time or treatment of [PtCl(RCN){NH=C(R)NC(Ph)=MHPH}] (**8–11**) with 2 more equiv of the amidine yields the complex bearing two chelate rings [Pt{NH=C(R)NC(Ph)=MHPH}₂] (**12–15**). The treatment of *cis*-[PtCl₂(RCN)₂] (R = Me, Et) with the amidine gives ca. 50–60% yield of [PtCl₂{NH=C(R)NHC(Ph)=MHPH}] (**16** and **17**). All of the platinum compounds were characterized by elemental analyses; FAB mass spectrometry; IR spectroscopy; ¹H, ¹³C{¹H}, and ¹⁹⁵Pt NMR spectroscopies, and four of them (**4**, **6**, **8**, and **15**) were also characterized by X-ray crystallography. The coupling of the Pt-bound nitriles and the amidine is metal-mediated insofar as RCN and PhC(=NH)NHPH do not react in the absence of the metal centers in conditions more drastic than those of the observed reactions. The nitrile–amidine coupling reported in this work constitutes a route to the synthesis of imidoamidine complexes, some of them exhibiting luminescent properties.

Introduction

The wealth of ligand reactivity patterns exhibited by metal-bound RC≡N species and their useful applications (e.g., the usage of nitriles as versatile synthons for the preparation of new compounds via C–O, C–N, C–C, C–P, and C–S bond making and the metal-catalyzed hydrolytic transformation of RCN species to amides of industrial and pharmacological significance) have triggered a large amount of studies

focused, in particular, on nucleophilic additions to ligands in (RCN)[M] complexes, and this topic has been the subject of comprehensive reviews and books,¹ including recent surveys by some of us.^{2–5} The analysis of experimental material collected to date^{1–5} shows that the largest fraction of works in this area is devoted to the creation of the C–N bond by the addition of ammonia and amines, hydrazines, and hydroxylamines as well as by the coupling of some nitrogen heterocycles with ligated RCN species;² for recent examples, see ref 6.

Despite the great number of examples of the metal-mediated RCN–amine integration, only a few reports deal with nitrile–imine (or *heteroimine*) coupling. Thus, all

studies known to date include platinum-mediated nitrile–imine coupling with the imines $\text{HN}=\text{ER}'\text{R}''$ ($\text{E} = \text{C}$, $\text{R}' = \text{R}'' = \text{Ph}$; $\text{E} = \text{S}$, $\text{R}'/\text{R}'' = \text{aryls}$; $\text{E} = \text{C}$, $\text{R}'/\text{R}'' = \text{Alkyl/OAlkyl}^{10}$) to give products of the type $\text{HN}=\text{C}(\text{R})-\text{N}=\text{ER}'\text{R}''_2$, which are difficult to obtain by conventional organic synthesis. Our current interest in the addition of imines to complexed nitriles has recently been sparked by the discovery of two unusual reactions mediated jointly by a Ni(II) center and a ketoxime (e.g., $\text{Me}_2\text{C}=\text{NOH}$; Scheme 1), that is, the formation of imidoamidines¹¹ (top) and phthalocyanines¹² (bottom). The triaza fragment of the two molecules shown in bold could be, at least formally, considered as derived from nitrile–amidine coupling, which, however, was not observed.

Hence, we now have to extend our investigations of reactions of metal-activated nitriles, in general,^{2–5} and of nitrile–imine coupling, in particular,^{7,9,10} to studies of the coupling between complexed nitriles and amidines. For this work, we addressed, on one hand, the kinetically inert (relative to other nitrile metal compounds) (nitrile)Pt(II and

Scheme 1

IV) complexes $[\text{PtCl}_n(\text{RCN})_2]$ ($n = 2, 4$), which proved to be superior models for investigations of the additions to nitriles, and, on the other hand, the easily accessible¹³ and soluble solid amidine $\text{HN}=\text{C}(\text{Ph})\text{NHPH}$, which can be handled as a stable free base. Our interest in studying the addition of the latter to the former was three-fold: (i) to observe nitrile coupling with a nucleophile of a novel type, that is, amidine; (ii) to verify the effect of the oxidation state of the Pt center on the addition of amidines to coordinated nitriles; and (iii) to develop an understanding of the mechanism for the formation of imidoamidines and phthalocyanines at a Ni(II) center.

Results and Discussion

Nitrile–Amidine Coupling at a Pt(IV) Center. Treatment of the platinum(IV) complexes $\text{trans-}[\text{PtCl}_4(\text{RCN})_2]$ ($\text{R} = \text{Me}, \text{Et}, \text{Ph}, \text{NEt}_2$) with 2 equiv of the amidine $\text{PhC}(\text{=NH})\text{NHPH}$ (Scheme 2) in a suspension of MeCN ($\text{R} = \text{Me}$), CHCl_3 ($\text{R} = \text{Et}, \text{Ph}$), or in a CHCl_3 solution ($\text{R} = \text{NEt}_2$) in the temperature range from 25 to 40 °C for 1–7 h (reaction time depends mostly on solubility of the starting material) results in the formation of the imidoamidine complexes $\text{trans-}[\text{PtCl}_4\{\text{NH}=\text{C}(\text{R})\text{N}=\text{C}(\text{Ph})\text{NHPH}\}_2]$ (**1–4**) isolated in good yields (66–84%). The reaction failed only in the case of $[\text{PtCl}_4(\text{PhCH}_2\text{CN})_2]$, where the formation of a broad mixture of products, which were not separated, was observed.

Complexes **1–4** gave satisfactory C, H, and N elemental analyses and the expected molecular ion/fragmentation patterns (typically $[\text{M} - n\text{Cl}]^+$, $n = 1–4$) in FAB^+ mass spectra. These four compounds were also characterized by IR and ^1H , $^{13}\text{C}\{^1\text{H}\}$, and ^{195}Pt NMR spectroscopies and (complex **4**; see below) by X-ray crystallography.

In the IR spectra, **1–4** exhibit one strong band in the range from 1645 to 1656 cm^{-1} , which corresponds to $\nu(\text{N}=\text{C})$ stretching vibrations of the monodentately coordinated imidoamidine species, and another band of $\nu(\text{N}=\text{C})$ appears on the interval between 1531 and 1537 cm^{-1} and overlaps with $\nu(\text{C}=\text{C})$ vibrations. Because of a very low solubility, **2** was characterized only by ^1H NMR, whereas **1** is so poorly

Scheme 2

Figure 1. Thermal ellipsoid view of complex **4** with atomic numbering scheme. Thermal ellipsoids are drawn at 50% probability. Selected bond lengths (Å) and angles (deg): Pt(1)–N(1) 2.036(4), Pt(1)–Cl(2) 2.3095(11), Pt(1)–Cl(1) 2.3249(11), N(1)–C(1) 1.301(6), N(1)–Pt(1)–N(1A) 180, N(1)–Pt(1)–Cl(1) 89.15(11), N(1)–Pt(1)–Cl(2) 82.58(12), Pt(1)–N(1)–C(1) 134.1(3).

soluble that it was not characterized even by the latter method. Complexes **3** and **4**, which are sufficiently soluble in the common deuterated solvents, were characterized by ¹H, ¹³C{¹H}, and ¹⁹⁵Pt NMR spectroscopies. In the ¹⁹⁵Pt spectra, both **3** and **4** exhibit two signals, which are probably due to their existence in two configurations; these signals are unlikely due to cis and trans isomers because (i) **3** and **4** were derived from the isomerically pure *trans*-[PtCl₄(RCN)₂] and subsequent *trans*-to-*cis* isomerization is unlikely for octahedral Pt(IV) complexes¹⁴ and (ii) both **3** and **4** display only one spot each on thin layer chromatography (TLC), whereas the geometric isomers of Pt complexes are usually strongly different in *R_f* values. All signals from the imidoylamidine ligand in the ¹H NMR spectrum of **4** are broad because of exchange processes in the coordinated NH=C(NEt₂)N=C(Ph)NHPh species such as, for example, dynamic *E*–*Z* isomerization observed recently, by some of us, in other Pt(IV)-bound diazadiene species.⁹

In the solid state, complex **4** has two imidoylamidine ligands in the mutually trans position and both are in *Z* configuration (Figure 1).

In the (*Z*)-NH=C(NEt₂)–N=C(Ph)–NHPh fragment, the N=C bond lengths [N(1)–C(1) and N(3)–C(6), 1.301(6) and 1.298(6) Å, respectively] correspond, within 3σ, to the typical double N=C bonds [1.279(8) Å in C_{Ar}–C=N–C¹⁵], whereas the N(3)–C(1) [1.365(6) Å], N(4)–C(6) [1.331(6) Å], and N(2)–C(1) [1.357(6) Å] distances belong to the typical single N–C bonds [e.g., Nsp²–Csp² in amides 1.346(11) Å¹⁵]. All of these observations demonstrate the absence of electron delocalization in the imine ligand. A similar phenomenon has been observed in the guanidine complexes [PtI₂{NH=C(NEt₂)₂}(NHEt₂)],¹⁶ [PdCl₂{NPh=C-

(NHPH)₂],¹⁷ and [Co(NH₃)₅{NH=C(NH₂)NMe₂}]²⁺,¹⁸ where the guanidine ligands have distinct single and double CN bonds with no electron delocalization.

Dehydrochlorination of 3 and 4. In coordination chemistry, the carbonyl-stabilized phosphorus ylides Ph₃P=CHCO₂R display two principal reactivity modes; that is, they act as C-donor ligands toward metal centers¹⁹ and as nucleophiles in the addition to metal-activated organonitriles²⁰ and alkenes.²¹ Rather recently, we discovered an efficient method for the generation of (imine)Pt(II) compounds that involves *reduction* (i.e., a third reactivity pattern of the ylides in coordination chemistry) of the corresponding readily available Pt(IV)-based imines by Ph₃P=CHCO₂R in nonaqueous media.²² We attempted to apply the latter technique to the reduction of **3** and **4** (low solubility of **1** and **2** precluded our endeavors) and treated these complexes with 2 equiv of Ph₃P=CHCO₂Me in CH₂Cl₂ (40 °C, 5 h). In contrast to our expectations, instead of the reduction, we observed the *dehydrochlorination* of **3** and **4**, resulting in chelate ring closure (Scheme 2) to furnish **5** and **6**, respectively, and the phosphonium salt [Ph₃PCH₂CO₂Me]-

Figure 2. Thermal ellipsoid view of complex **6** with atomic numbering scheme. Thermal ellipsoids are drawn at 50% probability. Selected bond lengths (Å) and angles (deg): Pt(1)–N(1) 2.018(2), Pt(1)–N(4) 2.054(3), Pt(1)–Cl(2) 2.3313(8), N(1)–Pt(1)–N(4) 92.95(10), N(1)–Pt(1)–Cl(2) 87.53(8), N(4)–Pt(1)–Cl(2) 87.44(7).

Cl. Treatment of **6** with 3 equiv of $\text{Ph}_3\text{P}=\text{CHCO}_2\text{Me}$ at 50 °C for 5 d resulted in only 30% conversion to the corresponding Pt(II) complex $[\text{Pt}\{\text{NH}=\text{C}(\text{NEt}_2)\text{NC}(\text{Ph})=\text{NPh}\}_2]$ (**15**). The reduction can be achieved within several minutes, when $\text{Ph}_2\text{PCH}_2\text{CH}_2\text{PPh}_2$ (dppe) in CDCl_3 is used. However, in the latter case, (imidoylamidinato)Pt^{II} complex **15** is contaminated with the solid $[\text{Pt}(\text{dppe})_2]\text{Cl}_2$.

In the IR spectra of **5** and **6**, in contrast to those of **3** and **4** (where strong bands at 1656 and 1645 cm^{-1} , correspondingly, from $\nu(\text{N}=\text{C})$ in the monodentately bound imidoamidinate were observed), there is a strong band at 1550 (**5**) and 1556 cm^{-1} (**6**); its appearance is typical for the bidentate-bound imidoamidines in the platinum(II) complexes (see below). Complex **5** was not analyzed by NMR spectroscopy because of its poor solubility in the most common deuterated solvents. In the ^1H and $^{13}\text{C}\{^1\text{H}\}$ NMR spectra of **6**, all signals from the organic ligand are well-resolved, reflecting the absence of the proton exchange or a rotation in the ligand, which is observed for the coordinated imidoamidinate species in complex **4**. Compound **6** exhibits one signal in the ^{195}Pt NMR spectrum at 103 ppm, in the region characteristic for some other *trans*- $[\text{PtCl}_4(\text{imine})_2]$ complexes.²³

The X-ray structure was obtained for **6** (Figure 2). The bond lengths, N(1)–C(1) [1.318(4) Å], N(2)–C(1) [1.358(4) Å], N(3)–C(1) [1.357(4) Å], N(3)–C(6) [1.316(4) Å], and N(3)–C(6) [1.335(4) Å], in the metallacycle are similar within 3σ with those found in complex **4** for the monodentately coordinated ligand. Similar to **4**, bond delocalization was not observed in the NCNCN fragment. The metallacycles are distorted square planes: torsion angles are Pt(1)–

C(1)–N(3)#1, 8.4(4); Pt(1)–N(4)–C(6)–N(3), 18.6(4); and C(1)#1–N(3)–C(6)–N(4), 7.1(5); the maximum deviation of the N(1) atom from the plane Pt(1)N(1)C(1)N(3)C(6)N(4) is 0.196(3) Å [N(1), –0.145(3) Å; N(3), –0.159(3) Å], and the root mean square of the deviations from the plane is 0.203(3) Å.

Hence, in the reaction with **3** and **4**, the phosphorus ylide $\text{Ph}_3\text{P}=\text{CHCO}_2\text{Me}$ abstracts HCl, acting as a base, and this reactivity mode is the fourth one observed in coordination chemistry for the carbonyl-stabilized phosphorus ylides.

Nitrile–Amidine Coupling at a Pt(II) Center. The route of the reaction between the platinum(II) complexes $[\text{PtCl}_2(\text{RCN})_2]$ and the amidine $\text{PhC}(\text{=NH})\text{NPh}$ depends on the *cis/trans* configuration of the starting metal complex (Scheme 3, A²⁴), the molar ratio of the reactants, and the reaction time. In this section, we will consider first the nitrile–amidine coupling at *trans*- $[\text{PtCl}_2(\text{RCN})_2]$ (R = Et, Ph, CH_2Ph , NEt_2 ; the acetonitrile complex was not employed because of its very poor solubility), whereupon the coupling with the nitriles in *cis*- $[\text{PtCl}_2(\text{RCN})_2]$ (R = Me, Et) will be described.

When *trans*- $[\text{PtCl}_2(\text{RCN})_2]$ was reacted with 2 equiv of the amidine (Scheme 3, B), two products were isolated from the reaction mixture. The first one corresponds to the addition of one amidine to the nitrile C atom of *trans*- $[\text{PtCl}_2(\text{RCN})_2]$ and the ring closure of the imidoamidinate ligand formed in the metal-mediated reaction, that is, $[\text{PtCl}(\text{RCN})\{\text{NH}=\text{C}(\text{R})\text{NC}(\text{Ph})=\text{NPh}\}]$ (**8–11**); another product released from the reaction mixture is the hydrochloride $[\text{PhC}(\text{=NH})\text{NPh}]\cdot\text{HCl}$ (**7**; characterized by FAB⁺ MS and X-ray crystallography, see Experimental Section and the Supporting Information). When *trans*- $[\text{PtCl}_2(\text{RCN})_2]$ reacts with 4 equiv of the amidine under a prolonged reaction time (Scheme 3, C) or $[\text{PtCl}(\text{RCN})\{\text{NH}=\text{C}(\text{R})\text{NC}(\text{Ph})=\text{NPh}\}]$ (**8–11**) is treated with 2 more equiv of the amidine (Scheme 3, D), the complex bearing two chelate rings $[\text{Pt}\{\text{NH}=\text{C}(\text{R})\text{NC}(\text{Ph})=\text{NPh}\}_2]$ (**12–15**) is formed. We discovered that the latter group of complexes represents a new class of efficient Pt-based luminophores showing pH-dependent phosphorescence previously not recognized by others.²⁵ These results include the photophysical properties of $[\text{Pt}\{\text{NH}=\text{C}(\text{R})\text{NC}(\text{Ph})=\text{NPh}\}_2]$.²⁶

When *cis*- $[\text{PtCl}_2(\text{RCN})_2]$ (R = Me, Et; ca. 80:20% *cis/trans* mixtures) reacts with the amidine, the latter couples with one RCN moiety with the substitution of the other RCN for the other end of the bidentate imidoamidinate (Scheme 3, E). The reaction proceeds at 40 °C for 1 h to give ca. 50–60% yield of $[\text{PtCl}_2\{\text{NH}=\text{C}(\text{R})\text{NHC}(\text{Ph})=\text{NPh}\}]$ (**16** and **17**).

In a related work, Baker and colleagues treated benzamidine hydrochloride, $\text{PhC}(\text{=NH})\text{NH}_2\cdot\text{HCl}$, with two equiv of

Scheme 3

Li(*Bu-n*) in diethyl ether, with a further reaction of Li[(NH)₂CPh], obtained in situ, with the platinum(II) complex [PtCl₂(PhCN)₂].²⁵ Nucleophilic addition of (NH)₂CPh⁻ to the ligated benzonitrile gave the azametallacycle, depicted in Scheme 4.

Scheme 4

The X-ray crystal structure was determined, but the poor quality of crystals and, consequently, high estimated standard deviations precluded any solid conclusions on bond delocalization within the metallacycle. Hence, the structure of the product in Scheme 4 is given in accord with our observations. Our experiments, in contrast to those of the previous work,²⁵ show that additional activation of amidines toward the coupling, by deprotonation, is not necessary and amidines are sufficiently nucleophilic in these reactions.

Characterization of (Imido)amidinoPt(II) Complexes.

All complexes give satisfactory elemental analyses for the proposed formulation. In FAB⁺ MS, the complexes [PtCl(RCN){NH=C(R)NC(Ph)=NPh}] give fragmentation patterns characteristic for platinum chlorides with the following ions: [M - Cl]⁺, [M - RCN]⁺, [M - RCN - Cl]⁺ (**8–11**), and [M]⁺ or [M + H]⁺ for [Pt{NH=C(R)NC(Ph)=NPh}₂] (**12–15**). There are two types of imidoamidino complexes that were prepared from *trans*-[PtCl₂(RCN)₂] (R = Et, Ph, CH₂Ph, NEt₂), which are [PtCl(RCN){NH=C(R)NC(Ph)=NPh}] (**8–11**) and [Pt{NH=C(R)NC(Ph)=NPh}₂] (**12–15**). These compounds do not have intense bands at ca. 1650 cm⁻¹, but they exhibit a strong band at 1540–1561

cm⁻¹, which could be attributed to ν(C=N); ν(C=C) (from Ar) might contribute to the overall intensity. The ν(C≡N) vibrations were detected for complexes **10** and **11**. In the ¹H NMR spectra, complexes **8–15** exhibit one signal for the NH group, at 5.56–7.34 ppm for **8–11** and 3.84–6.38 ppm for **12–15**. In the ¹³C{¹H} spectra of [PtCl(RCN){NH=C(R)NC(Ph)=NPh}] (**8–10**), the signal from the RCN (R = Et, Ph, PhCH₂) moiety appears at 109.65–118.08 ppm. ¹³C signals of the C=N group vary in the range 158.66–187.03 ppm for the NH=C and 145.86–151.82 ppm for the NPh=C fragments. Complexes **8–15** exhibit one signal in the ¹⁹⁵Pt NMR spectra in the range from -2145 to -2296 ppm; this range agrees well with ¹⁹⁵Pt NMR parameters for other (imino)Pt(II) complexes.^{22,23}

In the IR spectra, complexes [PtCl₂{NH=C(R)NHC(Ph)=NPh}] (R = Me, **16** and R = Et, **17**) exhibit strong bands at 1685 and 1688 cm⁻¹, respectively, from ν(C=N) and, in the ¹H NMR spectra, two signals from the two different NH hydrogens (10.07 and 7.39 for **16**; 11.33 and 9.98 for **17**).

The structures of **8** and **15** were determined by X-ray single-crystal diffraction (Figures 3 and 4), and it was observed that both have square planar geometry. Atoms of the metallacycles lie in one plane with a maximum deviation of 0.045(2) Å for N(2), 0.028(1) Å for Pt(1), and 0.028(2) Å for C(7) in Pt(1)N(2)C(4)N(3)C(7)N(4), and the root mean square of the deviations for this ring is 0.039(2) Å in **8**. The N=C bond lengths [N(2)C(4), 1.305(3) and N(4)C(7), 1.323(3) Å for **8**] and the N-C bond lengths [N(3)C(4), 1.338(4) and N(3)C(7), 1.342(3) Å for **8**] in the metallacycle have values typical for bonds in Ni(II) imidoamidino(ato) complexes.^{11,27} Complex **15** has another, based on bond

Figure 3. Thermal ellipsoid view of complex **8** with atomic numbering scheme. Thermal ellipsoids are drawn at 50% probability. Selected bond lengths (Å) and angles (deg): Pt(1)–N(1) 1.987(2), Pt(1)–N(2) 1.945(2), Pt(1)–N(4) 1.998(2), Pt(1)–Cl(2) 2.3015(6), N(1)–C(3) 1.126(3), N(1)–Pt(1)–N(2) 177.35(8), N(2)–Pt(1)–N(4) 88.98(9), N(1)–Pt(1)–N(4) 93.40(9), N(1)–Pt(1)–Cl(2) 88.92(6), Pt(1)–N(1)–C(3) 177.0(2).

Figure 4. Thermal ellipsoid view of complex **15** with atomic numbering scheme. The asymmetric unit contains a complete molecule and two halves (labeled B and C). Thermal ellipsoids are drawn at 50% probability. Selected bond lengths (Å) and angles (deg): Pt(1)–N(1) 2.000(3), Pt(1)–N(4) 2.023(3), Pt(1)–N(5) 2.003(3), Pt(1)–N(7) 2.032(3), Pt(1B)–N(1B) 2.005(3), Pt(1B)–N(4B) 2.040(3), Pt(1C)–N(1C) 2.000(3), Pt(1C)–N(4C) 2.028(3), N(1)–Pt(1)–N(4) 87.33(12), N(5)–Pt(1)–N(7) 87.54(12), N(1B)–Pt(1B)–N(4B) 87.42(13), N(1C)–Pt(1C)–N(4C) 87.68(13).

lengths, distribution of double and single CN bonds in the metallacycle [N(1)C(1), 1.318(4) Å; C(1)N(3), 1.357(4) Å; N(3)C(6), 1.316(4) Å; and C(6)N(4), 1.335(4) Å], which can be related to the influence of the NEt₂ group, but all values still remain typical, within 3σ, for such types of imidoamidinate(ato) metallacycles. Atoms of the metallacycles lie in one plane, with a maximum deviation of 0.016(4) Å for N(1) and 0.013(4) Å for N(4) in Pt(1)N(1)C(1)N(3)C(6)N(4), and the root mean square of the deviations for this ring is 0.019(3) Å in **15**.

Final Remarks. Heating of the free nitriles (in particular, PhCN as the most reactive toward the nucleophilic addition among chosen for this study) and the amidine PhC(=NH)NHPPh gave no reaction for at least 1 d, whereas the coordinated nitriles react rapidly under milder conditions. These observations provide explicit evidence for the metal-mediated character of the coupling. Moreover, it is clear that Pt(IV) provides a better activation toward the coupling than

the Pt(II) center does, and Pt(II) shows a stepwise pattern for the reaction. Thus, for the Pt(II) complexes, the reaction between [PtCl₂(RCN)₂] and PhC(=NH)NHPPh leads to the addition of amidine to the coordinated nitrile followed by the coordination of the newly formed imidoamidinate via the NHPPh end to the Pt(II) center with a ring closure accompanied by the leaving behind of one of the ligands (Cl[−] or RCN).

Hence, the nitrile–amidinate coupling reported herein constitutes a route to the synthesis of imidoamidinate complexes,^{11,27} some of them, as we have also found,²⁶ exhibiting useful luminescent properties. In addition, results from this study support the hypothesis that nitrile–amidinate coupling could be one of the plausible steps in the recently discovered Ni(II)/oxime-mediated conversion of nitriles to imidoamidines¹¹ and phthalonitriles.¹²

Experimental Section

Materials and Instrumentation. Solvents were obtained from commercial sources and used as received. PhC(=NH)NHPPh,¹³ [PtCl₂(RCN)₂], and [PtCl₄(RCN)₂] (R = Me, Et, Ph, CH₂Ph, NEt₂) were prepared in accord with the published method.²⁸ Positive-ion FAB mass spectra were obtained on a Trio 2000 instrument by bombarding 3-nitrobenzyl alcohol (NBA) matrixes of the samples with 8 keV (ca. 1.28 × 10¹⁵ J) Xe atoms. Mass calibration for data system acquisition was achieved using CsI. Infrared spectra (400–4000 cm^{−1}) were recorded on a Nicolet magna 750 FT/IR instrument using KBr pellets. TLC were performed on Merck 60 F₂₅₄ SiO₂ plates. ¹H, ¹³C{¹H}, and ¹⁹⁵Pt NMR spectra were measured on Bruker-DPX 300 and Varian UNITY 300 spectrometers at ambient temperature. ¹⁹⁵Pt chemical shifts (measured on a Varian UNITY 300 spectrometer) are given relative to Na₂[PtCl₆] (by using K₂[PtCl₄], δ = −1630, as a standard), and the half-height line width is given in parentheses.

Nitrile–Amidinate Coupling at a Pt(IV) Center. A solution of the amidine HN=C(Ph)NHPPh (97 mg, 0.49 mmol) in CH₂Cl₂ (2 mL) was added dropwise while stirring at room temperature to a suspension of [PtCl₄(RCN)₂] (R = Me, Et, Ph, NEt₂) (0.24 mmol) in CH₂Cl₂ (3 mL). For R = Me, the reaction mixture was stirred at room temperature overnight until completeness of the reaction, and for the other cases (R = Et, Ph, NEt₂), the reaction mixture was left to stand at 40 °C for 1, 7, and 3 h, respectively. For R = Me, Et, and Ph, poorly soluble product was filtered off, washed with Et₂O (three 5-mL portions), and dried in the air, whereas for R = NEt₂, the reaction mixture was evaporated and the yellow oily residue released was crystallized under a layer of Et₂O and dried on air at 20–25 °C. Yields are 66–84%.

[PtCl₄{NH=C(Me)N=C(Ph)NHPPh}₂] (**1**). Anal. Calcd for C₃₀H₃₀N₆Cl₄Pt·2H₂O: C, 42.52; H, 4.04; N, 9.92. Found: C, 42.50; H, 3.65; N, 10.21%. FAB⁺ MS, *m/z*: 812 [M – H]⁺, 788 [M – Cl]⁺, 740 [M – 2HCl]⁺, 705 [M – 2HCl – Cl]⁺. mp = 178 °C. TLC: *R*_f = 0.37 (eluent: CH₂Cl₂). IR (KBr, selected bands, cm^{−1}): 3404 (w), ν(O–H); 3299 (m), 3265 (w), ν(N–H); 1655 (s), ν(C=N); 1535 (s), ν(C=N and C=C from Ar); 773 (w), 693 (m), δ(C–H). The compound is insoluble in all common deuterated solvents, and this precluded NMR measurements.

[PtCl₄{NH=C(Et)N=C(Ph)NHPPh}₂] (**2**). Anal. Calcd for C₃₂H₃₄N₆Cl₄Pt·H₂O: C, 44.82; H, 4.23; N, 9.80. Found: C, 44.97;

127.17, 125.73 (CPh); 42.65 and 13.37 (Et₂NC=N). ¹⁹⁵Pt NMR (CDCl₃, δ): 103 (305 Hz).

The Nitrile–Amidine Coupling at Pt(II) Center. Reaction of trans-[PtCl₂(RCN)₂] and the Amidine (2 Equiv). trans-[PtCl₂(RCN)₂] (0.053 mmol) and PhC(=NH)NHPPh (21 mg, 0.106 mmol) were dissolved in CH₂Cl₂ (0.5 mL) and left overnight at 40 °C. The released colorless crystals of the amidinium hydrochloride were removed by filtration, and the filtrate was evaporated until dryness under a vacuum at room temperature to form a pale-yellow powder of the platinum complexes, which were recrystallized from CH₂-Cl₂-Et₂O to give analytically pure samples. Yields of 8–11 after crystallization were 50–60%. The amidinium hydrochloride (7) was also detected in the reaction mixture.

[PhC(=NH)NHPPh]·HCl (7). Colorless crystals, insoluble in CH₂Cl₂. FAB⁺ MS, *m/z*: 197 [M]⁺. For X-ray structure, see Supporting Information.

$\nu(\text{C}\equiv\text{N})$; 1559 (s), $\nu(\text{C}=\text{N}$ and $\text{C}=\text{C}$ from Ar); 1469 (s), $\nu(\text{C}=\text{C}$ from Ar); 701 (m), $\delta(\text{C}-\text{H})$. ¹H NMR (CDCl₃, δ): 7.02 (m, 9H, Ph), 6.83 (t, 1H, *o*-Ph), 7.10 (t, 2H, *m*-Ph), 7.07 (m, 5H, Ph), 5.56 (s, br, 1H, NH), 3.41 (q, 4H) and 1.17 (t, 6H) (Et₂NC=N), 2.75 (q, 4H) and 1.01 (t, 6H) (Et₂NC=N). ¹³C{¹H} NMR (CDCl₃, δ): 187.03 (C=N-H); 151.82 (C=N-Ph); 129.53 (C_{ipso}); 128.63, 128.13, 127.17, 126.85, 126.60, 124.20 (carbons in Ph's); 45.19 and 12.76 (Et₂NC=N); 42.85 and 13.51 (Et₂NC=N). ¹⁹⁵Pt NMR (CDCl₃, δ): -2273 (788 Hz).

Reaction of *trans*-[PtCl₂(RCN)₂] and the Amidine (4 Equiv). General Method B. *trans*-[PtCl₂(RCN)₂] (0.053 mmol) (R = Et, NEt₂) and PhC(=NH)NHPH (42 mg, 0.212 mmol) were dissolved in CH₂Cl₂ (0.5 mL) and left at 40 °C. For R = Et, the pale-yellow needles appeared on the top of the vial after 3 d. They were filtered off and mechanically separated from the colorless crystals of byproduct PhC(=NH)NHPH·HCl. For R = Et, crystals can be dissolved in warm CH₂Cl₂; the solvent was separated from the colorless crystals and evaporated to give the product. For R = NEt₂, after 5 d, a yellow solution with colorless crystals of PhC(=NH)NHPH·HCl (7) was obtained, the crystals were filtered off, and the filtrate was evaporated to half of its volume, whereupon Et₂O (0.2 mL) was added dropwise. The released yellow precipitate was filtered off, washed with Et₂O (0.5 mL), and dried. Yields: 50 and 35% for R = Et and NEt₂, respectively. The complexes with R = CH₂Ph (13) and Ph (14) are prepared analogously.

[Pt{NH=C(Et)NC(Ph)NPh}₂] (12). Anal. Calcd for C₃₂H₃₂N₆-Pt·Et₂O: C, 55.73; H, 5.09; N, 11.47%. Found: C, 55.75; H, 4.87; N, 11.41%. FAB⁺ MS, *m/z*: 696 [M + H]⁺. mp = 207 °C (dec). TLC: *R*_f = 0.47 (eluent CH₂Cl₂/acetone = 1:1). IR (KBr, selected bands, cm⁻¹): 3347 (m), $\nu(\text{N}-\text{H})$; 1632 (m), $\nu(\text{C}=\text{N})$; 1561 (ms), $\nu(\text{C}=\text{N}$ and $\text{C}=\text{C}$ from Ar); 1446 (s), 1430 (s), $\nu(\text{C}=\text{C}$ from Ar); 697 (ms), $\delta(\text{C}-\text{H})$. ¹H NMR (CDCl₃, δ): 7.22 (t, 2H, *m*-Ph), 7.05 (m, 8H, Ph), 5.77 (s, br, 1H, NH), 2.04 (q, 7.5 Hz, 2H) and 0.56 (t, 7.5 Hz, 3H) (EtC=N). ¹³C{¹H} NMR (CDCl₃, δ): 163.03 (C=N-H); 145.86 (C=N-Ph); 128.85, 128.29, 127.47, 127.24, 125.99 (carbons in Ph's); 32.92 and 9.48 (EtC=N). ¹⁹⁵Pt NMR (CDCl₃, δ): -2145 (538 Hz).

[Pt{NH=C(CH₂Ph)NC(Ph)NPh}₂] (13). Anal. Calcd for C₄₂H₃₆N₆Pt: C, 61.53; H, 4.43; N, 10.25. Found: C, 61.49; H, 4.80; N, 10.26%. FAB⁺ MS, *m/z*: 820 [M]⁺. IR (KBr, selected bands, cm⁻¹): 3339 (ms), $\nu(\text{N}-\text{H})$; 1558 (s), $\nu(\text{C}=\text{N}$ and $\text{C}=\text{C}$ from Ar); 1448 (s), $\nu(\text{C}=\text{C}$ from Ar); 697 (ms), $\delta(\text{C}-\text{H})$. ¹H NMR (CDCl₃, δ): 7.22 and 7.01 (m, 15H, Ph), 5.61 (s, br, 1H, NH),

3.30 (m, 4.5 Hz, 2H, N=CCH₂Ph). ¹³C{¹H} NMR (CDCl₃, δ): 129.26, 128.57, 127.60, 127.47, 127.31, 126.88, 126.20 (carbons in Ph) (PhCH₂C=N and C=N were not detected). ¹⁹⁵Pt NMR (CDCl₃, δ): -2261 (540 Hz).

[Pt{NH=C(Ph)NC(Ph)NPh}₂] (14). Anal. Calcd for C₄₀H₃₂N₆-Pt: C, 60.68; H, 4.07; N, 10.61. Found: C, 60.54; H, 4.52; N, 10.60%. FAB⁺ MS, *m/z*: 792 [M]⁺. IR (KBr, selected bands, cm⁻¹): 3350 (ms), $\nu(\text{N}-\text{H})$; 1540 (s), $\nu(\text{C}=\text{N}$ and $\text{C}=\text{C}$ from Ar); 1465 (ms), $\nu(\text{C}=\text{C}$ from Ar); 702 (m), $\delta(\text{C}-\text{H})$. ¹H NMR (CDCl₃, δ): 7.30 (m, 4H), 7.16 (m, 8H) and 7.08 (m, 3H) (Ph), 6.38 (s, br, 1H, NH). ¹³C{¹H} NMR (CDCl₃, δ): 156.15 and 156.05 (2 C=N); 129.11, 128.40, 128.06, 127.59, 127.22, 126.39, 125.85 (carbons in Ph). ¹⁹⁵Pt NMR (CDCl₃, δ): -2270 (520 Hz).

[Pt{NH=C(NEt₂)NC(Ph)NPh}₂] (15). Anal. Calcd for C₃₆H₄₂N₈Pt: C, 55.30; H, 5.41; N, 14.33. Found: C, 55.46; H, 5.61; N, 13.93%. FAB⁺ MS, *m/z*: 783 [M + H]⁺. mp = 209 °C. TLC: *R*_f = 0.47 (eluent Et₂O/CH₂Cl₂ = 1:4). IR (KBr, selected bands, cm⁻¹): 3392 (ms), $\nu(\text{N}-\text{H})$; 1541 (s), $\nu(\text{C}=\text{N}$ and $\text{C}=\text{C}$ from Ar); 1471 (s), $\nu(\text{C}=\text{C}$ from Ar); 695 (m), $\delta(\text{C}-\text{H})$. ¹H NMR (CDCl₃, δ): 7.11 and 7.08 (2 m, 10H, Ph), 3.84 (s, br, 1H, NH), 2.81 (q, 4H) and 0.79 (t, 6H) (Et₂NC=N). ¹³C{¹H} NMR (CDCl₃, δ): 160.82 (C=N-H); 150.57 and 147.79 (C=N-Ph); 129.52, 129.28, 128.70, 128.53, 127.77, 127.17, 126.75, 126.09, 124.87, 122.32 (carbons in Ph's); 41.85 and 13.70 (Et₂NC=N). ¹⁹⁵Pt NMR (CDCl₃, δ): -2259 (441 Hz).

Reaction of *cis*-[PtCl₂(RCN)₂] and the Amidine (2 Equiv). A solution of the amidine HN=C(Ph)NHPH (106.8 mg, 0.54 mmol) in CHCl₃ (2 mL) was added dropwise to a suspension of *cis*-[PtCl₂(EtCN)₂] (100 mg, 0.27 mmol) in CHCl₃ (3 mL) {or *cis*-[PtCl₂(MeCN)₂] in MeCN}. The reaction mixture was left to stand for 1 h at 40 °C; during this time, a pale-yellow powder of the product started to release. The product was filtered off, washed with Et₂O (three 4-mL portions), and dried in the air. Yield is 50–60%.

[PtCl₂{NH=C(Me)N=C(Ph)NHPH}] (16). Anal. Calcd for C₁₅H₁₅N₃Cl₂Pt: C, 35.80; H, 3.00; N, 8.35. Found: C, 36.14; H, 3.36; N, 8.50%. FAB⁺ MS, *m/z*: 503 [M]⁺, 468 [M - Cl + H]⁺. The compound has no characteristic mp; upon heating, it decomposes above 255 °C. TLC: *R*_f = 0.70 (eluent CH₂Cl₂/acetone = 1:1). IR (KBr, selected bands, cm⁻¹): 3345 (m), 3230 (m), 3187 (m), $\nu(\text{N}-\text{H})$; 1685 (s), 1629 (ms), $\nu(\text{C}=\text{N})$; 1527 (s), $\nu(\text{C}=\text{C}$ from Ar); 696 (m), $\delta(\text{C}-\text{H})$. ¹H NMR (DMSO-*d*₆, δ): 10.07 (s, br, 1H, NH), 7.39 (s, br, 1H, NH), 6.8–7.2 (m, 10H, two Ph), 1.99 (s, 3H, Me).

[PtCl₂{NH=C(Et)N=C(Ph)NHPh}] (**17**). Anal. Calcd for C₁₆H₁₇N₃Cl₂Pt: C, 37.15; H, 3.31; N, 8.12. Found: C, 37.27; H, 3.33; N, 7.84%. FAB⁺ MS, *m/z*: 517 [M]⁺, 482 [M - Cl + H]⁺, 444 [M - 2HCl]⁺. The compound has no characteristic mp, and upon heating, it decomposes above 285 °C. TLC: *R_f* = 0.60 (eluent CH₂Cl₂/acetone = 3:1). IR (KBr, selected bands, cm⁻¹): 3349 (m), 3230 (m), 3188 (m), ν(N-H); 1688 (s), 1628 (ms), ν(C=N); 1529 (s), ν(C=C from Ar); 807 (m), 695 (m), δ(C-H). ¹H NMR (DMSO-*d*₆, δ): 11.33 (s, br, 1H, NH), 9.98 (s, br, 1H, NH), 6.3–7.3 (m, 10H, 2 Ph), 3.32 (q, 7.4 Hz, 2H, CH₂), 1.14 (t, 7.4 Hz, 3H, CH₃).

X-ray Structure Determinations. The X-ray diffraction data were collected with a Nonius Kappa CCD diffractometer. The Denzo-Scalepack²⁹ or EvalCCD³⁰ program packages were used for cell refinements and data reduction. Structures were solved by direct methods using the SHELXS-97 or SIR-2002 programs.^{31,32} A multiscan absorption correction based on equivalent reflections (XPREP in SHELXTL version 6.12 or SADABS version 2.05)^{33,34} was applied to all data (*T*_{min}/*T*_{max} values were 0.5345/0.8168, 0.14737/0.22322, 0.22453/0.26323, 0.3136/0.7040, and 0.12102/0.20939 for **4**, **6–8**, and **15**, respectively). All structures were refined with SHELXL-97³⁵ and the WinGX graphical user interface.³⁶ In **4**, NH hydrogens were located from the difference Fourier

map and refined isotropically. In **8**, NH hydrogens were also located from the difference Fourier map but not refined. All other hydrogens were placed in idealized positions and constrained to ride on their parent atom. The asymmetric unit of **15** contains a complete molecule and two halves, which have been labeled as molecules B and C. The crystallographic details for **4**, **6**, **8**, and **15** are summarized in Table 1, and the selected bond lengths and angles are found in the figure captions. The crystallographic details of **7** are given as Supporting Information.

Acknowledgment. This work has been supported by the Russian Fund for Basic Research (Grants 03-03-32363 and 05-03-32140) and the Fundação para a Ciência e a Tecnologia (FCT), Portugal, and its POCTI program (POCTI/QUI/43415/2001 project) (FEDER funded). N.A.B., M.H., and V.Yu.K. thank the Academy of Finland for financial support. N.A.B. and V.Yu.K. express gratitude to the POCTI program, Portugal, for Grant SFRH/BPD/11448/2002 (N.A.B.) and a grant for Cientista Convitado/Professor at the Instituto Superior Técnico (V.Yu.K.). V.Yu.K. is very much obliged to ISSEP for a Soros Professorship (2001–2004). The authors also thank NATO for the Collaborative Linkage Grant PST.CLG.979289.

Supporting Information Available: Crystallographic data in CIF format. Tables of crystallographic data, atomic coordinates, bond lengths and angles, anisotropic displacement parameters, hydrogen coordinates and isotropic displacement parameters, torsion angles, and hydrogen bonds for **4**, **6**, **7**, **8**, and **15**. Thermal ellipsoid view of **7**. This material is available free of charge via the Internet at <http://pubs.acs.org>.
