Received March 15, 2007

The hydrothermal synthesis and structural characterization of a number of complex compounds containing the divalent tris(oxalato-*O,O'*)germanate anion, $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$, or the neutral bis(oxalato-*O,O'*)germanium fragment, $[\text{Ge}(\text{C}_2\text{O}_4)_2]$, with transition-metal (M) cationic complexes of 1,10'-phenanthroline (phen) is reported: $[\text{M}(\text{phen})_3]\text{[Ge}(\text{C}_2\text{O}_4)_3\cdot x\text{H}_2\text{O}]$ [where $\text{M}^{2+} = \text{Cu}^{2+}$ (**1a** and **1b**), Fe^{2+} (**2a** and **2b**), Ni^{2+} (**3**), Co^{2+} (**4**); $x = 0.2$ for **2b**], $[\text{MGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$ [where $\text{M}^{2+} = \text{Cd}^{2+}$ (**5**) and Cu^{2+} (**6**)]. The isolation of two polymorphs with Cu^{2+} (**1a** and **1b**) and other pseudo-polymorphs for Fe^{2+} (**2a** and **2b**) was rationalized based on slightly different molar ratios for the starting materials. All compounds have been characterized using EDS, SEM, vibrational spectroscopy (FT-IR and FT-Raman), thermogravimetry, and CHN elemental composition and their structure determined on the basis of single-crystal X-ray diffraction studies. The crystal packing of the different chemical moieties for each series of compounds was discussed on the basis of the various intermolecular interactions present (strong C–H $\cdots\pi$ and weak C–H $\cdots\text{O}$ hydrogen-bonding interactions, C–H $\cdots\pi$ and π – π contacts).

Introduction

In recent years, research on crystalline organic–inorganic hybrid oxalates has gained great interest in materials science due to the structural diversity of these compounds which range from discrete complexes^{1–4} to 1D chains,^{5–7} 2D layers,^{8,9} and 3D open frameworks.^{10–12} Moreover, some of

these materials find interesting potential applications arising from their peculiar architectures such as zeolite-like frameworks¹³ and the inherent properties of the metallic centers, for example, photoluminescence arising from the presence of lanthanides.¹⁴

Following our ongoing research on crystalline the hybrid materials,^{15–25} we recently focused our attention on the use

Scheme 1

of germanium centers.^{26,27} These often exhibit two distinct oxidation states, +2 and +4, with the latter being the most stable at ambient conditions and commonly appearing in inorganic compounds (such as GeO_2) and germanate frameworks.^{28,29} In addition, Ge^{4+} centers exhibit a number of distinct coordination numbers and environments, namely, four (often tetrahedral),^{30–32} five (square pyramidal or trigonal bipyramidal),^{31,33–36} and six (often octahedral),^{37,38} a crucial feature in order to achieve topological diversity for the frameworks.

Here we wish to report the first complex-based heterodimetallic crystalline compounds containing the divalent tris-(oxalato- O,O')germanate anion crystallizing with a number of transition-metal (M) complexes with 1,10'-phenanthroline (phen) organic residues, $[\text{M}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3] \cdot x\text{H}_2\text{O}$ [where $\text{M}^{2+} = \text{Cu}^{2+}$ (**1a** and **1b**), Fe^{2+} (**2a** and **2b**), Ni^{2+} (**3**), Co^{2+} (**4**); $x = 0.2$ for **2b**] (Scheme 1). Furthermore, the first examples of binuclear complexes containing the neutral bis-(oxalato- O,O')germanium fragment $[\text{Ge}(\text{C}_2\text{O}_4)_2]$ are reported,

Scheme 2

which is instead connected by two μ_2 -bridging hydroxyl groups to a cationic $[\text{M}(\text{phen})_2]^{2+}$ fragment, $[\text{MGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$ [where $\text{M}^{2+} = \text{Cd}^{2+}$ (**5**) and Cu^{2+} (**6**)] (Scheme 2). For the former series of compounds, two polymorphs for Cu^{2+} , and a pseudo-polymorph for Fe^{2+} could be isolated by employing slightly different synthetic procedures. Remarkably, searches in the literature and the Cambridge Structure Database (CSD, Version 5.28 Nov 2006)^{39,40} reveal that only a handful of structures containing $[\text{Ge}(\text{C}_2\text{O}_4)_{3-x}]^{2(x-1)}$ moieties are known to date, all comprising small organic molecules or K^+ as the counterions.^{41–44}

Experimental Section

General. Chemicals were readily available from commercial sources and used as received without further purification: amorphous germanium(IV) oxide (GeO_2 , 99.99%, Aldrich), oxalic acid dihydrate ($\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$, $\geq 99\%$, Panreac), 1,10'-phenanthroline monohydrate (phen, $\text{C}_{12}\text{H}_8\text{N}_2 \cdot \text{H}_2\text{O}$, $\geq 99.0\%$, Fluka), copper(II) acetate tetrahydrate ($\text{Cu}_4\text{H}_6\text{O}_4 \cdot 4\text{H}_2\text{O}$, 98%, Panreac), nickel(II) acetate tetrahydrate ($\text{Ni}_4\text{H}_6\text{O}_4 \cdot 4\text{H}_2\text{O}$, $\geq 99\%$, Riedel-deHaën), cobalt(II) acetate tetrahydrate ($\text{Co}_4\text{H}_6\text{O}_4 \cdot 4\text{H}_2\text{O}$, 98%, Panreac), cadmium(II) acetate dihydrate ($\text{Cd}_4\text{H}_6\text{O}_4 \cdot 2\text{H}_2\text{O}$, 98%, Fluka), ammonium ferrous sulfate hexahydrate $[(\text{NH}_4)_2\text{Fe}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$, 99%, Merck], and potassium ferric oxalate $[\text{KFe}(\text{C}_2\text{O}_4)_2]$, 99%, Ventron].

Instrumentation. Elemental analyses for C, H, and N were performed in a CHNS-932 elemental analyzer in the Microanalysis Laboratory of the University of Aveiro.

Thermogravimetric analyses (TGA) were carried out using a Shimadzu TGA 50 with a heating rate of 5 °C/min under a continuous flow of air with rate of 20 cm^3/min .

Scanning electron microscopy (SEM) and energy dispersive analysis of X-rays spectroscopy (EDS) were performed using a Hitachi S-4100 field emission gun tungsten filament instrument working at 25 kV. Samples were prepared by deposition on aluminum sample holders and were carbon coated.

FT-IR spectra were collected from KBr pellets (Aldrich, 99%+, FT-IR grade) on a Mattson 7000 FT-IR spectrometer. Fourier Transform Raman (FT-Raman) spectra (range 4000–100 cm^{-1})

were recorded on a Bruker RFS 100 spectrometer with a Nd:YAG coherent laser ($\lambda = 1064$ nm).

Synthesis of [Cu(phen)₃][Ge(C₂O₄)₃] (1a). A mixture containing 0.06 g of GeO₂, 0.18 g of H₂C₂O₄·2H₂O, 0.10 g of CuC₄H₆O₄·H₂O, and 0.20 g of phen was mixed in ca. 15 g of distilled water and stirred at ambient temperature for 30 min. The resulting homogeneous suspension, with approximate molar composition of 1:3:1:2, respectively, was transferred to an autoclave (ca. 40 mL) and heated at 100 °C for 72 h. Large single crystals of [Cu(phen)₃][Ge(C₂O₄)₃] were directly obtained from the autoclave contents along with some small impurities (later identified as compound **6**, see below) which could not be eliminated by physical separation. The sample was washed with copious amounts of distilled water, filtrated, and air-dried under ambient conditions (yield 49.0% based on CuC₄H₆O₄·H₂O).

Calculated elemental composition (based on single-crystal data for C₄₂H₂₄N₆O₁₂CuGe, MW 940.80; %): C 53.62, N 8.93, H 2.57. Found for the as-synthesized bulk material (%): C 49.49, N 8.39, H 2.41. TGA data (weight losses inside parentheses): 205–341 °C (–40.7%); 341–599 °C (–35.3%). Selected FT-IR and Raman (inside parentheses and in italics) data (in cm⁻¹): $\nu(\text{C-H, aromatic}) = 3068\text{w}, 2933\text{w}, (3073)$; $\nu(\text{uncoordinated carbonyl groups}) = 1735\text{s}; \nu_{\text{asym}}(-\text{CO}_2^-) = 1676\text{s}, 1627\text{m}, 1588\text{w}, (1606, 1545)$; $\nu(\text{C-C, skeletal vibrations}) = 1518\text{m}, 1497\text{w}, (1446)$; $\delta(\text{C-H}) = 1428\text{s}, (1411)$; $\nu_{\text{sym}}(-\text{CO}_2^-) = 1428\text{s}, 1362\text{s}, 1330\text{s}, (1411)$; $\nu(\text{C-N, heteroaromatic amines}) = 1330\text{s}; \nu(\text{C-O}) = 1226\text{m}, 1198\text{w}, 1146\text{w}, (1296)$; $\nu(\text{C-C skeletal stretching mode}) = 1105\text{w}, (1054)$; $\nu(\text{C-H}) = 992\text{w}; \nu(\text{C-C and Ge-O}) = 893\text{w}, 845\text{m}, 819\text{s}, (807)$; $\delta(\text{CO}_2^-) = 775\text{w}, 725\text{s}, (721)$; $\gamma(\text{C-H}) = 644\text{w}, 595\text{w}; \nu(\text{M-N})$ and $\rho(\text{CO}_2^-) = 470\text{m}, 426\text{w}, (427)$.

Synthesis of [Cu(phen)₃][Ge(C₂O₄)₃] (1b). The synthetic procedure used to isolate this polymorph is identical to that described for **1a** but using instead a reaction mixture containing 0.050 g of GeO₂, 0.180 g of H₂C₂O₄·2H₂O, 0.095 g of CuC₄H₆O₄·H₂O, 0.300 g of phen, and 15 g of H₂O (approximate molar composition of 1GeO₂:3H₂C₂O₄:1CuC₄H₆O₄:3phen). Yield 95.6% based on CuC₄H₆O₄·H₂O.

Calculated elemental composition (based on single-crystal data for C₄₂H₂₄N₆O₁₂CuGe, MW 940.80; %): C 53.62, N 8.93, H 2.57. Found (%): C 53.50, N 8.72, H 2.54. TGA data (weight losses inside parentheses): 201–343 °C (–48.0%); 343–599 °C (–31.9%). Selected FT-IR and Raman (inside parentheses and in italics) data (in cm⁻¹): $\nu(\text{C-H, aromatic}) = 3059\text{w}, (3069)$; $\nu(\text{uncoordinated carbonyl groups}) = 1737\text{s}; \nu_{\text{asym}}(-\text{CO}_2^-) = 1669\text{w}, 1621\text{w}, 1588\text{w}, (1624, 1605, 1586)$; $\nu(\text{C-C, skeletal vibrations}) = 1515\text{m}, 1493\text{w}, (1449)$; $\delta(\text{C-H}) = 1425\text{m}, (1416)$; $\nu_{\text{sym}}(-\text{CO}_2^-) = 1425\text{m}, 1318\text{s}, (1416, 1307)$; $\nu(\text{C-N, heteroaromatic amines}) = 1318\text{s}, (1307)$; $\nu(\text{C-O}) = 1225\text{m}, 1191\text{w}, 1139\text{w}; \nu(\text{C-C skeletal stretching mode}) = 1102\text{w}, (1053)$; $\nu(\text{C-H}) = 1000\text{w}, 965\text{w}; \nu(\text{C-C and Ge-O}) = 892\text{m}, 853\text{m}, 821\text{s}; \delta(\text{CO}_2^-) = 778\text{w}, 724\text{m}, (735)$; $\gamma(\text{C-H}) = 645\text{w}, 593\text{w}; \nu(\text{M-N})$ and $\rho(\text{CO}_2^-) = 470\text{m}, 420\text{w}, (425)$.

Synthesis of [Fe(phen)₃][Ge(C₂O₄)₃] (2a). The synthetic procedure used to isolate [Fe(phen)₃][Ge(C₂O₄)₃] is identical to that described for **1a** with the reaction mixture containing instead 0.050 g of GeO₂, 0.140 g of H₂C₂O₄·2H₂O, 0.110 g of KFe(C₂O₄)₂, 0.200 g of phen, and 15 g of H₂O (approximate molar composition of 1GeO₂:2H₂C₂O₄:2/3KFe(C₂O₄)₂:2phen). Yield 58.1% based on KFe(C₂O₄)₂.

Calculated elemental composition (based on single-crystal data for C₄₂H₂₄N₆O₁₂FeGe, MW 933.11; %): C 54.06, N 9.01, H 2.59. Found (%): C 53.70, N 8.76, H 2.49. TGA data (weight losses inside parentheses): 277–353 °C (–59.0%); 353–598 °C (–21.0%).

Selected FT-IR and Raman (inside parentheses and in italics) data (in cm⁻¹): $\nu(\text{C-H, aromatic}) = 3076\text{w}, (3076)$; $\nu(\text{uncoordinated carbonyl groups}) = 1734\text{s}, (1763)$; $\nu_{\text{asym}}(-\text{CO}_2^-) = 1671\text{m}, 1631\text{w}, 1577\text{w}, (1632, 1602, 1580)$; $\nu(\text{C-C, skeletal vibrations}) = 1512\text{w}, 1494\text{w}, (1513, 1454)$; $\delta(\text{C-H}) = 1425\text{s}, (1431)$; $\nu_{\text{sym}}(-\text{CO}_2^-) = 1425\text{s}, 1363\text{w}, 1328\text{s}, (1431, 1345, 1304)$; $\nu(\text{C-N, heteroaromatic amines}) = 1328\text{s}, (1304)$; $\nu(\text{C-O}) = 1227\text{s}, 1197\text{m}, 1140\text{w}, (1208, 1142, 1105)$; $\nu(\text{C-C skeletal stretching mode}) = 1096\text{w}, 1054\text{w}, (1055)$; $\nu(\text{C-H}) = 987\text{w}, (911)$; $\nu(\text{C-C and Ge-O}) = 892\text{m}, 842\text{s}, 819\text{s}, (877)$; $\delta(\text{CO}_2^-) = 771\text{w}, 721\text{s}, (739)$; $\gamma(\text{C-H}) = 645\text{w}, 595\text{w}, 532\text{w}, (646)$; $\nu(\text{M-N})$ and $\rho(\text{CO}_2^-) = 470\text{m}, (439)$.

Synthesis of [Fe(phen)₃][Ge(C₂O₄)₃]·0.2H₂O (2b). The synthetic procedure used to isolate this hydrated polymorph of [Fe(phen)₃][Ge(C₂O₄)₃] is identical to that described for **1a** but using instead (NH₄)₂Fe(SO₄)₂·6H₂O as the Fe²⁺ source. The reaction mixture contained 0.050 g of GeO₂, 0.180 g of H₂C₂O₄·2H₂O, 0.130 g of (NH₄)₂Fe(SO₄)₂·6H₂O, 0.200 g of phen, and 15 g of H₂O (approximate molar composition of 1GeO₂:3H₂C₂O₄:2/3(NH₄)₂Fe(SO₄)₂·6H₂O:2phen). Yield 53.5% based on (NH₄)₂Fe(SO₄)₂·6H₂O.

Calculated elemental composition (based on single-crystal data for C₄₂H_{24.40}N₆O_{12.20}FeGe, MW 936.72; %): C 53.85, N 8.97, H 2.63. Found (%): C 53.12, N 8.68, H 2.64. TGA data (weight losses inside parentheses): 30–268 °C (–0.8%); 268–342 °C (–59.8%); 342–599 °C (–18.8%). Selected FT-IR and Raman (inside parentheses and in italics) data (in cm⁻¹): $\nu(\text{C-H, aromatic}) = 3071\text{m}, (3071)$; $\nu(\text{uncoordinated carbonyl groups}) = 1740\text{s}, (1765, 1727)$; $\nu_{\text{asym}}(-\text{CO}_2^-) = 1672\text{s}, 1614\text{s}, (1630, 1600, 1580)$; $\nu(\text{C-C, skeletal vibrations}) = 1517\text{m}, 1494\text{w}, (1513, 1453)$; $\delta(\text{C-H}) = 1424\text{s}, (1427)$; $\nu_{\text{sym}}(-\text{CO}_2^-) = 1424\text{s}, 1358\text{m}, 1313\text{s}, (1427, 1341, 1299)$; $\nu(\text{C-N, heteroaromatic amines}) = 1313\text{s}, (1299)$; $\nu(\text{C-O}) = 1218\text{m}, 1186\text{w}, 1141\text{w}, (1206, 1141)$; $\nu(\text{C-C skeletal stretching mode}) = 1105\text{w}, (1106, 1056)$; $\nu(\text{C-C and Ge-O}) = 893\text{m}, 849\text{m}, 817\text{s}, (875)$; $\delta(\text{CO}_2^-) = 725\text{s}, (741)$; $\gamma(\text{C-H}) = 646\text{w}, 596\text{w}, 530\text{w}, (647, 596)$; $\nu(\text{M-N})$ and $\rho(\text{CO}_2^-) = 470\text{m}, 420\text{w}, (437)$.

Synthesis of [Ni(phen)₃][Ge(C₂O₄)₃] (3). The synthetic procedure used to isolate [Ni(phen)₃][Ge(C₂O₄)₃] is identical to that described for **1a** but using instead NiC₄H₆O₄·4H₂O as the Ni²⁺ source. The reaction mixture contained 0.050 g of GeO₂, 0.180 g of H₂C₂O₄·2H₂O, 0.080 g of NiC₄H₆O₄·4H₂O, 0.200 g of phen, and 15 g of H₂O (approximate molar composition of 1GeO₂:3H₂C₂O₄:2/3NiC₄H₆O₄:2phen). Yield 53.5% based on NiC₄H₆O₄·4H₂O.

Calculated elemental composition (based on single-crystal data for C₄₂H₂₄N₆O₁₂NiGe, MW 935.97; %): C 53.90, N 8.98, H 2.58. Found (%): C 52.98, N 9.01, H 2.55. TGA data (weight losses inside parentheses): 280–374 °C (–44.9%); 374–599 °C (–34.5%). Selected FT-IR and Raman (inside parentheses and in italics) data (in cm⁻¹): $\nu(\text{C-H, aromatic}) = 3073\text{w}, (3079)$; $\nu(\text{uncoordinated carbonyl groups}) = 1737\text{s}, (1759, 1721)$; $\nu_{\text{asym}}(-\text{CO}_2^-) = 1676\text{s}, 1627\text{m}, 1588\text{w}, (1627, 1611, 1588)$; $\nu(\text{C-C, skeletal vibrations}) = 1518\text{m}, 1497\text{w}, (1517, 1461)$; $\delta(\text{C-H}) = 1428\text{s}, (1423)$; $\nu_{\text{sym}}(-\text{CO}_2^-) = 1428\text{s}, 1362\text{s}, 1330\text{s}, (1423, 1362, 1345, 1322, 1311)$; $\nu(\text{C-N, heteroaromatic amines}) = 1330\text{s}, (1322, 1311)$; $\nu(\text{C-O}) = 1226\text{m}, 1198\text{w}, 1146\text{w}, (1258, 1206, 1146)$; $\nu(\text{C-C skeletal stretching mode}) = 1105\text{w}, (1056)$; $\nu(\text{C-H}) = 992\text{w}, (905)$; $\nu(\text{C-C and Ge-O}) = 893\text{w}, 845\text{m}, 819\text{s}, (872)$; $\delta(\text{CO}_2^-) = 775\text{w}, 725\text{s}, (733)$; $\gamma(\text{C-H}) = 644\text{w}, 595\text{w}, (597, 560)$; $\nu(\text{M-N})$ and $\rho(\text{CO}_2^-) = 470\text{m}, 426\text{w}, (514, 485, 426)$.

Synthesis of [Co(phen)₃][Ge(C₂O₄)₃] (4). The synthetic procedure used to isolate [Co(phen)₃][Ge(C₂O₄)₃] as a microcrystalline light-yellow powder is identical to that described for **1a** but using

Synthesis of [CuGe(phen)₂(μ_2 -OH)₂(C₂O₄)₂] (6). [CuGe(phen)₂(μ_2 -OH)₂(C₂O₄)₂] was initially isolated from the reaction vials of **1a** as a minor impurity. The pure phase was isolated using the same synthetic procedure with a reaction mixture composed of 0.050 g of GeO₂, 0.120 g of H₂C₂O₄·H₂O, 0.100 g of CuC₄H₆O₄·H₂O, 0.200 g of phen, and 15 g of H₂O (approximate molar composition of 1GeO₂:2H₂C₂O₄:1CuC₄H₆O₄:2phen). Yield 70.8% based on CuC₄H₆O₄·H₂O.

Calculated elemental composition (for C₂₈H₁₈N₄O₁₀CuGe, MW 706.59, %): C 47.60, N 7.93, H 2.57. Found (%): C 47.96, N 7.90, H 2.55. TGA data (weight losses inside parentheses): 105–197 °C (–0.5%); 197–342 °C (–31.6%); 342–599 °C (–42.4%). Selected FT-IR and Raman (inside parentheses and in italics) data (in cm^{–1}): $\nu(\text{O}-\text{H}$ as bridging ligand) = 3396m; $\nu_{\text{asym}}(\text{C}-\text{H}$, aromatic rings) = 3086w, (3078); $\nu(\text{uncoordinated carbonyl groups}) = 1719\text{s}; \nu_{\text{asym}}(-\text{CO}_2^-) = 1660\text{s}, 1597\text{s}, (1607)$; $\nu(\text{C}-\text{C}$, heteroaromatic amines) = 1519m, (1457); $\delta(\text{C}-\text{H}) = 1428\text{s}, (1429)$; $\nu_{\text{sym}}(-\text{CO}_2^-) = 1428\text{s}, 1363\text{s}, (1429, 1310)$; $\nu(\text{C}-\text{N}$, heteroaromatic amines) = 1363s; (1310); $\nu(\text{C}-\text{O}) = 1296\text{m}, 1248\text{m}, 1145\text{w}; \nu(\text{C}-\text{C}$ skeletal stretching mode) = 1107w, (1050); $\nu(\text{C}-\text{H}) = 1034\text{w}; \nu(\text{C}-\text{C}$ and Ge–O) = 854m, 808m;

$\delta(\text{CO}_2^-) = 724\text{s}, (736)$; $\gamma(\text{C}-\text{H}) = 647\text{w}, 574\text{w}, (560)$; $\nu(\text{M}-\text{N})$ and $\rho(\text{CO}_2^- \text{ out-of-plane}) = 483\text{m}, 429\text{w}, (432)$.

Single-Crystal X-ray Diffraction. Crystals of compounds [M(phen)₃][Ge(C₂O₄)₃]·xH₂O [where M²⁺ = Cu²⁺ (**1a** and **1b**), Fe²⁺ (**2a** and **2b**), Ni²⁺ (**3**); x = 0.2 for **2b**] and [MGe(phen)₂(μ_2 -OH)₂(C₂O₄)₂] [where M²⁺ = Cd²⁺ (**5**) and Cu²⁺ (**6**)] suitable for single-crystal X-ray diffraction analysis were manually harvested from the reaction vials and mounted on glass fibers using FOMBLIN Y perfluoropolyether vacuum oil (LVAC 25/6) purchased from Aldrich.⁴⁵ Data were collected in Nonius-based Kappa Bruker diffractometers equipped with charge-coupled device (CCD) area detectors and Mo K α ($\lambda = 0.7107$ Å) or Cu K α ($\lambda = 1.54180$ Å) (for **3**) radiation. Data were corrected for Lorentzian and polarization effects. Absorption corrections were applied using the multiscan semiempirical method implemented in SADABS.⁴⁶ Structures were solved using the direct methods of SHELXS-97,⁴⁷ which allowed immediate location of the heaviest atoms. The remaining non-hydrogen atoms were located from difference Fourier maps calculated from successive full-matrix least-squares refinement cycles on F^2 using SHELXL-97.⁴⁸ All non-hydrogen atoms were successfully refined using anisotropic displacement parameters.

Hydrogen atoms bound to carbon were located at their idealized positions by employing the *HFIX 43* instruction in SHELXL-97⁴⁸ and included in subsequent refinement cycles in riding motion approximation with isotropic thermal displacement parameters (U_{iso}) fixed at 1.2 U_{eq} of the carbon atom to which they were attached. In compounds **5** and **6** the hydrogen atoms associated with the μ_2 -bridging hydroxyl groups were markedly visible in the last difference Fourier maps synthesis. These atoms have been included in the final structural models with the O–H distances restrained to 0.95(1) Å in order to ensure a chemically reasonable geometry for these moieties, and with U_{iso} fixed at 1.5 U_{eq} of the parent oxygen atom.

In compound **2b** a partially occupied water molecule of crystallization [O(1W)] was directly located from difference Fourier maps and refined using an isotropic displacement parameter and a fixed partial site occupancy of 20% (determined previously by unrestrained refinement of this variable). Even though hydrogen atoms belonging to this chemical moiety could not be directly located from difference Fourier maps and no attempt was made to place these in approximate calculated positions, they have been included in the empirical formula of the compound. As mentioned in the previous section, crystals of **6** were obtained as a minor phase in the synthesis of **1a**. Crystals systematically showed poor quality associated with diffuse scattering at high angle (therefore, the high R_{int} ; see Table 1).

Information concerning the crystallographic data collection and structure refinement are collected in Table 1. Selected bond lengths and angles for compounds **1** to **3** are summarized in Tables 2 and 3, respectively, while for compounds **5** and **6** they are collected in Table 9. Geometrical details on the weak C–H···O hydrogen-bonding interactions interconnecting cationic [M(phen)₃]²⁺ and anionic [Ge(C₂O₄)₃]^{2–} moieties in compounds **1–3** are collected

(53) Rodriguez-Carvajal, J. *FULLPROF-A Program for Rietveld Refinement and Pattern Matching Analysis*, Abstract of the Satellite Meeting on Powder Diffraction of the XV Congress of the IUCR, Toulouse, France, 1990; p 127.

Le Bail whole-powder-diffraction-pattern profile fitting⁵⁸ (see Figure S1 in the Supporting Information) was performed with the FullProf.2k software package,^{53,54} employing a typical pseudo-Voigt peak-shape function, and in the last stages of the fitting process the unit cell parameters and typical profile parameters, such as scale factor, zero shift, Caglioti function values, and two asymmetry parameters were allowed to refine freely. Fixed background points were employed. The refined unit cell parameters converged to *a* = 19.204(2) Å, *b* = 20.839(2) Å, *c* = 9.511(1) Å, and β = 95.066(6)° (*R*_{Bragg} = 1.06% and χ² = 3.79)

Results and Discussion

A series of highly crystalline heterodimetallic complexes composed of tris(oxalato-*O,O'*)germanate anions and cationic complexes of transition metals (M) coordinated to 1,10'-phenanthroline (phen) residues have been isolated using mild hydrothermal synthesis, from reaction mixtures containing germanium(IV) oxide, oxalic acid, phen, and various M salts (see Experimental Section for details). Compounds have been formulated as [M(phen)₃][Ge(C₂O₄)₃·*x*H₂O] [where M²⁺ = Cu²⁺ (**1a** and **1b**), Fe²⁺ (**2a** and **2b**), Ni²⁺ (**3**), and Co²⁺ (**4**); *x* = 0.2 for compound **2b**] on the basis of single-crystal or powder X-ray diffraction studies and elemental analysis. EDS studies provided information on (1) the presence of Ge and the metallic centers on individual crystals of each compound and (2) the ratios of Ge:M, typically 1:1.

Crystalline phases were directly isolated from the autoclave contents in generous yields and usually as large single crystals, except for **4** which could only be synthesized as a microcrystalline powder (Figure 1). Phase purity and homogeneity of the bulk samples of **1b** and **2–4** have been confirmed by comparing the experimental powder X-ray diffraction patterns with simulations based on single-crystal data. Compound **1a** was systematically isolated with a small amount of compound **6** which could not be eliminated either at the synthesis stage or after. Nevertheless, according to the CHN elemental composition of several representative bulk samples of **1a** we determined that the amount of this impurity was quite small. However, during our synthetic attempts to eliminate this second-phase (by varying the composition of the reaction mixture used to isolate **1a**) a second polymorphic (and pure) phase was isolated for a slightly higher amount of phen in the reaction mixture (see Experimental Section for details on the synthetic procedures).

It is also of considerable interest to mention that for Fe²⁺ two structures could also be isolated, [Fe(phen)₃][Ge(C₂O₄)₃] (**2a**) and [Fe(phen)₃][Ge(C₂O₄)₃·0.2H₂O] (**2b**), with the latter

^a Symmetry transformation used to generate equivalent atoms: (i) $-x, y, 1.5 - z$.

being a solvate of the former and typically obtained for a slightly higher concentration of oxalic acid in the reaction mixture (see Experimental Section). This extra partially occupied water molecule of crystallization induces long-range structural modifications in the crystal packing, namely, a reduction in crystal symmetry from the monoclinic to the triclinic crystal systems (see structural details in the following paragraphs).

Structural Details of the $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ Anion. The chemical moiety common to structures **1–4** is the divalent tris(oxalate-*O, O'*)germanate anion, $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ (Figure 2 and Scheme 1). A search in the literature and in the CSD^{39,40} reveals only a handful of crystallographic reports^{41–44} describing this anion which, invariably, shows identical coordination geometry for all compounds, including those reported herein. The Ge^{4+} center appears coordinated to three oxalate anions (coordinated via a typical *anti, anti*-chelate bidentate fashion), describing a slightly distorted $\{\text{GeO}_6\}$ octahedral coordination fashion as depicted in Figure 2. The Ge–O bonds (for all five crystal structure determinations reported here) are found in the 1.865(2)–1.897(2) Å (Table 2), while the *cis* and *trans* O–Ge–O octahedral angles are instead in the 85.64(8)–95.83(8)° and 170.87(9)–177.28(10)° ranges, respectively (Table 3). These values are in good agreement with those described for the aforementioned related compounds available in the literature, which show an average Ge–O bond length of ca. 1.88 Å plus average

cis (or chelate bite angle) and *trans* O–Ge–O octahedral angles of 85.7° and 173.6°, respectively.^{41–44}

Crystal Structure Description of $[\text{Cu}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]$ (1a** and **1b**).** Two crystalline forms of $[\text{Cu}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]$, **1a** and **1b**, have been isolated from hydrothermal synthesis (see Experimental Section), crystallizing in the $P2_1/n$ and $P2_1/c$ monoclinic space groups, respectively. For both crystalline materials the asymmetric unit comprises two discrete (and charged) crystallographically independent divalent residues: one $[\text{Cu}(\text{phen})_3]^{2+}$ cation plus one $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ anion (Figure 3).

The crystallographically independent Cu^{2+} centers in **1a** and **1b** are coordinated by three phen organic ligands via a typical *N, N*-chelating coordination fashion, leading to distorted $\{\text{CuN}_6\}$ octahedral coordination geometries evidencing the typical Jahn–Teller distortion expected for these d^9 metallic centers: while the equatorial Cu–N bond lengths are found in the 2.021(2)–2.059(2) Å range, the apical interactions are much longer and within the 2.275(2)–2.374(2) Å range (Table 2), thus leading to a tetragonal distortion of the $\{\text{CuN}_6\}$ octahedra. The former bond lengths are well within the expected values, as revealed by a search in the CSD for structures containing $[\text{Cu}(\text{phen})_3]^{2+}$ cations (15 entries; range 2.01–2.34 Å), however, the latter values are slightly longer, in particular for **1b** (see Table 2). Such abnormal long Cu–N interactions with phen residues can be rationalized by taking into account intermolecular interac-

Figure 2. Anionic $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ fragment common to structures **1–4**. The represented structure was taken from the structure of complex **1b** and is represented with thermal ellipsoids drawn at the 50% probability level and showing the labeling scheme for all atoms. For selected bond lengths and angles related to this moiety in structures **1–3** see Tables 2 and 3, respectively.

Figure 3. Two crystallographic independent chemical moieties, $[\text{M}(\text{phen})_3]^{2+}$ and $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$, composing the crystal structures of **1–3** {from the refined structure of polymorph $[\text{Cu}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]$ (**1b**)} and showing the labeling scheme for all non-hydrogen atoms. Atoms are drawn as thermal ellipsoids at the 50% probability level, and hydrogen atoms have been omitted for clarity. For selected bond lengths and angles see Tables 2 and 3, respectively.

tions, in particular the weak $\text{C–H}\cdots\text{O}$ interactions which lead to local distortions in order to promote a more effective close packing (see following paragraphs). Structural distortions associated with **1b** are particularly well demonstrated by the *cis* octahedral angles whose range is the largest of all related structures reported herein (see Table 3).

The most remarkable structural feature which differentiates **1a** and **1b** structures concerns the number and type of

intermolecular $\text{C–H}\cdots\text{O}$ weak hydrogen bonds (not shown; Tables 4 and 5 collect some geometrical details of the most relevant and chemically feasible interactions) plus interactions of the $\text{C–H}\cdots\pi$ type and $\pi\text{–}\pi$ stacking between neighboring phen residues belonging to distinct cationic residues (Figure 4).⁵⁹ These supramolecular networks of weak intermolecular interactions establish physical connections between individual moieties and are responsible for completely distinct packing arrangements, as shown in Figure 5. Moreover, these interactions are ultimately the main reason responsible for the isolation of two distinct crystalline forms. In **1a** the $[\text{Cu}(\text{phen})_3]^{2+}$ cationic residues pack in chain-like arrangements along the [100] and [001] crystallographic directions (Figure 4a and 4b). While down the [100] direction adjacent $[\text{Cu}(\text{phen})_3]^{2+}$ cations interact only via $\text{C–H}\cdots\pi$ contacts [see Figure 4a; π represents the centroid of the neighboring adjacent aromatic ring; approximate $\text{C}\cdots\pi$ distances: H(19) 3.34 Å, H(20) 3.22 Å, H(40) 3.31 Å, H(41) 3.36 Å], along the [001] direction connections between neighboring complexes alternate between $\pi\text{–}\pi$ stacking and $\text{C–H}\cdots\pi$ interactions [$\text{C}(8)\text{–H}(8)\cdots\pi$ with $\text{C}\cdots\pi$ distance of 3.22 Å; see Figure 4b]. In **1b** only one structurally relevant $\text{C–H}\cdots\pi$ interaction was observed along the [001] direction of the unit cell [Figure 4c; $\text{C}(29)\text{–H}(29)\cdots\pi$ with $\text{C}\cdots\pi$ average distance of 3.20 Å]. Noteworthy is the fact that this contact seems to promote the unusually long Cu–N bonds discussed above. Indeed, in order to maximize the geometry associated with this $\text{C–H}\cdots\pi$ interaction, one coordinated phen residue needs to be slightly rotated. This leads, on one hand, to longer bond lengths (because of the structural rigidity of this organic ligand) and, on the other, to the large *cis* octahedral angles (see above). It is also of considerable importance to mention that adjacent phen residues in **1b** are too far apart (average distance of ca. 4.3 Å), thus invalidating the occurrence of $\pi\text{–}\pi$ stacking (as also depicted in Figure 4c).

Crystal Structure Description of $[\text{Fe}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]$ (2a**) and $[\text{Fe}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]\cdot 0.2\text{H}_2\text{O}$ (**2b**).** When Fe^{2+} is included in the reaction mixtures (see Experimental Section) two pseudo-polymorphic crystalline forms could be isolated with empirical formulas $[\text{Fe}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]$ and $[\text{Fe}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]\cdot 0.2\text{H}_2\text{O}$ for compounds **2a** and **2b**, respectively. Pseudo-polymorphism is defined as crystalline forms of a given compound (host) that differ in the chemical nature or stoichiometry of the included solvent molecules (guest) and refers to crystalline forms with solvent molecules as structurally relevant features of the structure (isolated lattice sites, lattice channels, or metal-ion-coordinated solvates).^{60,61}

The striking difference between these two compounds is the presence of one partially occupied (1/5) water molecule of crystallization in the asymmetric unit of **2b**, a unique feature among the series of compounds reported here. It is

Figure 4. Close packing of cationic $[\text{Cu}(\text{phen})_3]^{2+}$ fragments along the (a) [100] and (b) [001] crystallographic directions of polymorph **1a** and along the (c) [001] direction for polymorph **1b**, emphasizing the C–H $\cdots\pi$ and π – π interactions (dashed lines) interconnecting these moieties. For clarity, only the hydrogen atoms involved in the represented interactions are shown. Geometrical details (approximate C $\cdots\pi$ distances) on structurally relevant C–H $\cdots\pi$ interactions (π represents the centroid of the aromatic ring): C(19)–H(19) $\cdots\pi$ 3.34 Å; C(20)–H(20) $\cdots\pi$ 3.22 Å, C(40)–H(40) $\cdots\pi$ 3.31 Å, C(41)–H(41) $\cdots\pi$ 3.36 Å; C(8)–H(8) $\cdots\pi$ 3.22 Å; C(29)–H(29) $\cdots\pi$ 3.20 Å.

also of considerable interest to note that this occurrence seems to be the promoting structural reason for the decrease of crystal symmetry: **2b** crystallizes in the triclinic $P\bar{1}$ space group, while **2a** (as for all remaining heterometallic complex structures) is monoclinic (in this case described in the $P2_1/n$ space group) or higher. Disregarding the presence of water, the asymmetric units of **2a** and **2b** share many similarities with those described for the two previous compounds, comprising two crystallographically independent and charged ions: $[\text{Fe}(\text{phen})_3]^{2+}$ and $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$. The Fe^{2+} centers exhibit an almost regular $\{\text{FeN}_6\}$ octahedral coordination environment with the Fe–O bond lengths and *cis*- and *trans*-N–Fe–N octahedral angles being found in the 1.972(2)–2.002(2) Å (Table 2) and 82.58(8)–97.32(9)° and 171.75(9)–177.43(10)° (Table 3) ranges, respectively. These values are in agreement with those found in similar structures containing $[\text{Fe}(\text{phen})_3]^{2+}$ complexes, as revealed by a search in the CSD and in the literature.

The partially occupied water molecule of crystallization [O(1W)] is strongly hydrogen bonded to two neighboring divalent $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ anionic fragments, establishing a connection between these two moieties (Figure 6): O(1W) donates its two hydrogen atoms to O(7) and O(10) from distinct anions, with $d_{\text{O}\cdots\text{O}}$ of 3.031(2) and 2.881(1) Å, respectively. As also depicted in Figure 6, these bonding

interactions occur in symmetry-related pairs with the two water molecules being separated by 4.004(2) Å. The motif can be described by the $R_2^2(16)$ graph set notation.⁶²

As for **1a** and **1b** (see previous subsection), the crystal structure of these two pseudo-polymorphic compounds is assembled by extensive networks of weak C–H $\cdots\text{O}$ interactions involving the charged species. Chemically (and structurally) possible C $\cdots\text{O}$ intermolecular distances span from 3.028(2) to 3.564(3) Å for **2a** (Table 6) and from 3.037(3) to 3.513(4) Å for **2b** (Table 7). In the same way as for **1a**, in **2a** intermolecular interactions are composed of both C–H $\cdots\pi$ and π – π contacts between phen molecules belonging to neighboring $[\text{Fe}(\text{phen})_3]^{2+}$ complexes. While along the [100] direction connections are assured by only C–H $\cdots\pi$ interactions (as in Figure 4a), parallel to the [001] direction an alternation between C–H $\cdots\pi$ and π – π contacts is registered (as in Figure 4b).⁵⁹ In **2b** only C–H $\cdots\pi$ interactions (running parallel to the [100] crystallographic direction) are structurally relevant as physical connections between adjacent cationic residues (Figure 7).

The presence of the extra solvent molecule in **2b** also induces a completely distinct packing arrangement. While

(62) Bernstein, J.; Davis, R. E.; Shimoni, L.; Chang, N. L. *Angew. Chem., Int. Ed. Engl.* **1995**, *34*, 1555–1573.

Figure 5. Schematic representations of the crystal packing of (a) **1a** (along the [100] direction) and (b) **1b** (along the [010] direction). Hydrogen atoms have been omitted for clarity.

for **2a** the crystal packing is identical to that previously described for **1a** (as in Figure 5a), in **2b** $[\text{Fe}(\text{phen})_3]^{2+}$ cations alternate along the [010] direction of the unit cell with $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ anions, almost perfectly aligned in a typical eclipsed fashion (Figure 8). Interstitial spaces are occupied by the hydrogen-bonded water molecules of crystallization.

Crystallographic Aspects of $[\text{Ni}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]$ (3**) and $[\text{Co}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]$ (**4**).** $[\text{Ni}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]$ (**3**) crystallizes in the monoclinic $P2_1/n$ space group, as revealed by single-crystal X-ray diffraction (Table 1), and its molecular structure shares striking resemblances with those previously described for compounds **1a** and **2a** (see previous sections for details on the crystal structure). Relevant geometrical details associated with the Ge^{4+} and Ni^{2+} coordination environments of **3** are collected in Tables 2 and 3.

The compound with Co^{2+} , formulated as $[\text{Co}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]$ (**4**) on the basis of elemental analysis (and other supporting techniques), was also found to be isostructural

Figure 6. O—H \cdots O hydrogen-bonding interactions (dashed blue lines) involving the partially occupied water molecule of crystallization in pseudo-polymorph **2b**, $[\text{Fe}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]\cdot 0.2\text{H}_2\text{O}$, interconnecting neighboring $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ anionic fragments and leading to formation of a $R_4^4(16)$ graph set motif. Geometrical aspects of the represented hydrogen bonds: O(1W) j \cdots O(7) iii with $d_{\text{O}\cdots\text{O}}$ of 3.031(2) Å; O(1W) j \cdots O(10) with $d_{\text{O}\cdots\text{O}}$ of 2.881(1) Å. Symmetry transformations used to generate equivalent atoms: (i) $1-x, 2-y, 1-z$; (ii) $-1+x, y, z$; (iii) $-x, 2-y, 1-z$.

with **1a** and **2a** from powder X-ray diffraction studies (see details in the Experimental Section).

Crystal Structure Description of $[\text{MGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$ (where $\text{M}^{2+} = \text{Cd}^{2+}$ and Cu^{2+} for **5 and **6**).** The neutral hetero-binuclear compounds formulated as $[\text{MGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$ [where $\text{M}^{2+} = \text{Cd}^{2+}$ (**5**) and Cu^{2+} (**6**)] represent, to the best of our knowledge, the first examples of binuclear complexes containing a neutral bis(oxalate- O, O')germanium fragment, $[\text{Ge}(\text{C}_2\text{O}_4)_2]$, connected by two μ_2 -bridging hydroxyl groups to a cationic $[\text{M}(\text{phen})_2]^{2+}$ fragment (Figure 9). Moreover, a search in the literature reveals that these two isostructural complexes are also the first examples of hydroxyl-bridged $[\text{M}(\text{phen})_2]^{2+}$ fragments, and only a handful of structures are known to contain μ_2 -oxo bridges involving this fragment.^{63–75}

The neutral bis(oxalate- O, O') germanium fragment, $[\text{Ge}(\text{C}_2\text{O}_4)_2]$, shares structural similarities with the $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ complex discussed above and present in structures **1–4**. However, in **5** and **6** the Ge^{4+} center is only coordinated to

Figure 7. Close packing of cationic $[\text{Cu}(\text{phen})_3]^{2+}$ fragments in **2b** along the $[100]$ crystallographic direction, emphasizing the $\text{C}-\text{H}\cdots\pi$ interactions between neighboring residues. For clarity, only the hydrogen atoms involved in the represented interactions are shown. Geometrical details (approximate $\text{C}\cdots\pi$ distances) on structurally relevant $\text{C}-\text{H}\cdots\pi$ interactions (π represents the centroid of the aromatic ring): $\text{C}(38)-\text{H}(38)\cdots\pi$ 3.39 Å; $\text{C}(40)-\text{H}(40)\cdots\pi$ 3.66 Å.

two *O,O*-chelate oxalate anions, with the two remaining vacant positions in the coordination sphere being occupied by two μ_2 -bridging hydroxyl groups (Figure 9). The coordination environment of Ge^{4+} centers can thus be envisaged as distorted octahedra, $\{\text{GeO}_6\}$, with the $\text{Ge}-\text{O}$ bonds being found (for the two complexes) between 1.8166(10) and 1.951(8) Å while the *cis* and *trans* $\text{O}-\text{Ge}-\text{O}$ angles are in the $83.8(4)-97.12(5)^\circ$ and $167.40(6)-175.7(4)^\circ$ ranges, respectively (Table 9). The presence of μ_2 -bridging hydroxyl groups induces in the Ge^{4+} centers octahedral distortions greater than those observed for the $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ anions (Table 3) with this being essentially attributed to the stronger bonding nature of these chemical moieties. Consequently, the registered $\text{Ge}-\text{OH}$ bond distances are statistically smaller (below ca. 1.82 Å) than those with oxalate anions (always greater than ca. 1.90 Å; Table 9), even though they compare well with the only report in the literature containing a $\text{Ge}(\text{OH})-\text{M}$ bridge ($d(\text{Ge}-\text{OH})$ of about 1.78 Å) and present in an open-framework containing germanium clusters.⁷⁶ Moreover, the *trans* effect of these μ_2 -OH groups in the $\{\text{GeO}_6\}$ octahedra is also markedly present with the opposite $\text{Ge}-\text{O}_{\text{oxalate}}$ bonds [1.9413(10) and 1.951(8) Å for **5** and **6**, respectively] being the longest among all the structures reported here.

The M centers exhibit distorted octahedral coordination geometries composed by two symmetry-related *N,N*-chelating phen ligands plus two symmetry-related μ_2 -bridging hydroxyl groups, $\{\text{MN}_4\text{O}_2\}$ (Figure 9): the $\text{M}-(\text{N},\text{O})$ bond lengths are found in the 2.2967(10)–2.3385(12) and 1.989(10)–2.206(9) Å ranges for **5** and **6**, respectively; *cis* and *trans* internal octahedral angles can be found in the $65.81(5)-100.39(6)$ and $157.40(6)-162.11(4)^\circ$ (for **5**) and in the $68.8(4)-112.7(5)^\circ$ and $158.0(3)-170.2(6)^\circ$ ranges, respectively (see Table 9 for details). Noteworthy is the fact that for **6** the $\{\text{CuN}_4\text{O}_2\}$ coordination environment is not as significantly distorted as those registered for **1a** and **1b**, and consequently the Jahn–Teller distortion is not so markedly visible. It is feasible to assume that this smaller tetragonal distortion for **6** seems to arise mainly due to the presence of three crystallographically independent $\text{Cu}-(\text{N},\text{O})$ bond lengths, which are all statistically distinct as summarized in Table 9. The intermetallic $\text{Ge}(1)\cdots\text{M}(1)$ separations across the hydroxyl μ_2 bridge are 3.2487(3) and 3.1510(27) Å for **5** (Cd) and **6** (Cu), respectively.

Figure 8. Ball-and-stick packing arrangement of **2b** viewed along the crystallographic $[010]$ direction. Hydrogen atoms have been omitted for clarity.

The close packing in the solid state of individual $[\text{MGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$ complexes is mediated by a number of intermolecular interactions, in particular strong and highly directional $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonds involving anionic $[\text{Ge}(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]^{2-}$ fragments belonging to neighboring complexes: μ_2 -bridging hydroxyl groups donate their hydrogen atoms to neighboring oxalate anions [$\text{O}(5)-\text{H}(5\text{A})\cdots\text{O}(2)$]; for **5**, $d(\text{O}\cdots\text{O}) = 2.7699(15)$ Å with $\angle(\text{OHO}) = 170.3(2)^\circ$; for **6**, $d(\text{O}\cdots\text{O}) = 2.7791(13)$ Å with $\angle(\text{OHO}) = 168.0(1)^\circ$; symmetry operation (i) $-x, -y, 1-z$, leading to formation of a $R^2_2(12)$ graph set motif.⁶² The reciprocity of these hydrogen-bonding interactions leads to formation of 1D supramolecular tapes, $\infty^2[\text{MGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$, as depicted in Figure 10a. Interactions between adjacent tapes are assured by cooperative $\pi-\pi$ stacking involving the phen residues coordinated to the M centers (Figure 11).

Thermal Analysis. The thermal stability (under a continuous air flow) of $[\text{M}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]\cdot x\text{H}_2\text{O}$ [with $\text{M}^{2+} = \text{Cu}^{2+}$ (**1a** and **1b**), Fe^{2+} (**2a** and **2b**), Ni^{2+} (**3**), and Co^{2+} (**4**)] and $[\text{MGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$ [where $\text{M}^{2+} = \text{Cd}^{2+}$ (**5**) and Cu^{2+} (**6**)] was investigated between ambient temperature and ca. 600 °C with the registered thermograms (see Figure S2) clearly evidencing a similar behavior for all compounds belonging to a given family.

This study was particularly informative regarding the subtle composition difference between pseudo-polymorphs $[\text{Fe}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]$ (**2a**) and $[\text{Fe}(\text{phen})_3][\text{Ge}(\text{C}_2\text{O}_4)_3]\cdot 0.2\text{H}_2\text{O}$ (**2b**). Indeed, for the latter compound between

Figure 9. Schematic representation of the binuclear $[\text{CdGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$ (**5**) complex, showing the atom labeling for selected atoms and emphasizing the distorted octahedral coordination environments for the Cd^{2+} and Ge^{4+} metal centers. Non-hydrogen atoms composing the asymmetric unit are represented with thermal ellipsoids drawn at the 50% probability level. Hydrogen atoms were omitted for clarity. For selected bond lengths and angles for compounds **5** and **6** see Table 9. Symmetry transformation used to generate equivalent atoms: (i) $-x, y, 1.5 - z$.

ambient temperature and ca. 268 °C a small continuous weight loss of about 0.8% confirms the presence of a small amount of water present in the structure (calculated 0.4 per formula unit), which agrees with the structural assumptions deduced during the single-crystal X-ray diffraction studies.

Neglecting the initial weight loss of compound **2b** the thermal decomposition of all compounds can be roughly divided in two major stages: the first corresponds to release of a variable amount of phen ligands, and the second is attributed to decomposition of the $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ anions. It is noteworthy to mention that the first thermal decomposition starts to settle in for compounds **1a** and **1b** at a lower temperature (around 205 and 201 °C, respectively) than for the remaining materials (between 268 and 280 °C) with this phenomenon being ascribed to the stronger oxidizing properties of Cu^{2+} when compared with the remaining transition-metal centers. Nevertheless, in the 200–280 °C temperature range all materials release some phen ligands, usually between 2 and 3 molecules (**1a** ca. 2.1; **1b** ca. 2.5; **3** ca. 2.3; **4** ca. 2.4). In the case of the Fe^{2+} compounds all phen molecules are thermally removed. Upon thermal decomposition of the $[\text{Ge}(\text{C}_2\text{O}_4)_3]^{2-}$ anions, which usually starts to settle in around 300 °C, the obtained residues are composed of a mixture of metallic oxides which, except for **1a** (due to the presence of a small impurity in the as-synthesized material), are in good agreement with the expected stoichiometric quantities: for **1b**, $\text{CuO} + \text{GeO}_2$ (calculated 19.6%, observed 20.1%); for **2a** and **2b**, $\text{Fe}_2\text{O}_3 + \text{GeO}_2$ (calculated 19.8% and 19.7%, observed 20.0% and 20.6%, respectively); for

Figure 10. (a) Schematic representation of the parallel packing of individual $[\text{MGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$ complexes mediated by $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonds (dashed blue lines) and leading to formation of a one-dimensional supramolecular tape: $\infty^2[\text{MGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$. (b) Magnification of a portion of the supramolecular tape emphasizing the $R^2_2(12)$ graph set motif formed between two neighboring complexes and involving the μ_2 -bridging hydroxyl groups and coordinated oxalate anions. Geometrical details on $\text{O}(5)-\text{H}(5\text{A})\cdots\text{O}(2)$: for **5**, $d(\text{O}\cdots\text{O}) = 2.7699(15)$ Å with $\angle(\text{OHO}) = 170.3(2)^\circ$; for **6**, $d(\text{O}\cdots\text{O}) = 2.7791(13)$ Å with $\angle(\text{OHO}) = 168.0(1)^\circ$. Symmetry transformation used to generate equivalent atoms: (i) $-x, -y, 1 - z$. For clarity, only hydrogen atoms involved in hydrogen-bonding interactions are represented.

Figure 11. π - π Interactions (dashed green lines) interconnecting neighboring $\infty^2[\text{MGe}(\text{phen})_2(\mu_2\text{-OH})_2(\text{C}_2\text{O}_4)_2]$ supramolecular tapes. Hydrogen-bonding interactions are represented as dashed blue lines, and hydrogen atoms belonging to the phen residues have been omitted for clarity.

3, $\text{NiO} + \text{GeO}_2$ (calculated 19.2%, observed 19.6%); for **4**, $\text{CoO} + \text{GeO}_2$ (calculated 19.2%, observed 20.0%).

The thermal decomposition of compounds **5** and **6** starts with initial residual weight losses of about 0.6% and 0.5%, respectively, which agrees well with the release of two water molecules per formula unit (calculated values of ca. 0.5%). This can be attributed to destruction of the μ_2 bridges which interconnecting the metals within the complex which, as clearly observed in the thermograms, occurs at a significantly higher temperature for **5** than for **6**. Interestingly, the same is observed for the decomposition of the organic components of these compounds: while for **6**, at 600 °C, all the material was entirely converted into the expected stoichiometric

amount of CuO + GeO₂ (observed residual of 25.5%, calculated of about 26.06%), for **5** the decomposition is still occurring. The different kinetics associated with the thermal decomposition of **5** and **6** can be ascribed to the distinct physical-chemical properties of the M metals composing the bimetallic complexes with Cu²⁺ clearly promoting the decomposition.

Vibrational Spectroscopy. FT-IR and Raman spectra are particularly informative regarding the presence of the primary building blocks of the complexes, showing the characteristic bands of phen and oxalate organic ligands, hence fully supporting the chemical composition and structural details determined from the single-crystal X-ray diffraction studies.⁷⁷ Specific band assignments for the most intense and diagnostic bands are collected in the Experimental Section, while the FT-IR spectra are provided as Supporting Information (Figure S3).

A number of bands located between 810 and 900 cm⁻¹ are diagnostic of the presence of coordinated oxalate anions to Ge⁴⁺ and attributed to the $\nu(\text{C}-\text{C})$ and $\nu(\text{Ge}-\text{O}_{\text{oxalate}})$ stretching vibrational modes. Several intense bands found in the ca. 1100–1520 cm⁻¹ spectral region are characteristic of a number of vibrational modes of phen. A strong band centered at ca. 1735 cm⁻¹, particularly evident in all spectra, strongly supports the existence of uncoordinated (and terminal) C=O groups arising from the coordinated oxalate anions. Moreover, the $\nu_{\text{asym}}(-\text{CO}_2^-)$ and $\nu_{\text{sym}}(-\text{CO}_2^-)$ stretching vibrational bands of oxalate groups appear in the 1676–1580 and 1430–1310 cm⁻¹ spectral regions, respectively, which correspond to Δ values between 246 and 270 cm⁻¹, in good agreement with the observed *anti,anti*-chelate bidentate coordination fashion for these anionic moieties (see crystallographic description of the structures).^{78,79}

In the case of **5** and **6**, a broad band is markedly visible

above 3300 cm⁻¹ (centered at ca. 3321 cm⁻¹ for **5** and ca. 3396 cm⁻¹ for **6**) and attributed to the characteristic $\nu(\text{O}-\text{H})$ stretching vibrational band associated with the μ_2 -bridging hydroxyl groups involved in hydrogen bonds, in accord with the crystal structure.⁷⁷

Concluding Remarks

The preparation, via typical hydrothermal approaches, of the first bimetallic complexes containing either [Ge(C₂O₄)₃]²⁻ or [Ge(C₂O₄)₂] with M cationic complexes of 1,10'-phenanthroline (phen) and their full structural description based on single-crystal X-ray diffraction investigations has been described. It was shown that the large chemical species composing each complex structure close pack in the solid state mediated by extensive subnetworks of intermolecular interactions which include, among others, strong O–H···O and weak C–H···O hydrogen-bonding interactions, C–H··· π and π – π contacts.

Acknowledgment. We are grateful to FEDER, POCI 2010, and Fundação para a Ciência e Tecnologia (FCT, Portugal) for their generous financial support, funding toward the purchase of the single-crystal diffractometer, and also postdoctoral research grants (no. SFRH/BPD/9309/2002 (to F.-N.S.) and SFRH/BPD/14410/2003 (to L.C.-S.)). We also thank the EPSRC (U.K.) and the University of Leeds for equipment funding.

Supporting Information Available: Crystallographic information as CIF files; Le Bail whole-powder-diffraction-pattern profile fitting of [Co(phen)₃][Ge(C₂O₄)₃]; thermograms and FT-IR spectra for all compounds. This material is available free of charge via the Internet at <http://pubs.acs.org>.
