Received March 28, 2008

Metal selenites and tellurites are a class of very important compounds. In this paper, the structures and properties of metal selenites or tellurites combining with transition-metal (TM) ions with the  $d^0$  electronic configuration or tetrahedral  $MO_4$  building blocks of post-transition main-group elements were reviewed. Most compounds in the alkali or alkaline-earth- $d^0$  TM–Se<sup>IV</sup> (or Te<sup>IV</sup>)–O systems exhibit extended anionic architectures composed of distorted octahedra of ( $d^0$ ) TM cations and tellurite or selenite groups. The distortion of the octahedron is always away from the lone-pair cation, and some of them exhibit excellent second-order nonlinear optical properties due to the adductive effects of two types of bond polarizations. Because of the high coordination number of Ln<sup>III</sup> ions, most of compounds in the Ln- $d^0$  TM–Se<sup>IV</sup> (or Te<sup>IV</sup>)–O systems are not second-harmonic-generation active; however, they are able to emit strong luminescence in the visible or near-IR region; also in most cases, the  $d^0$  TM cations are in tetrahedral geometry and are well separated from selenite or tellurite groups. It is also interesting to note that the selenite group is normally “isolated”, whereas the TeO<sub>x</sub> ( $x = 3–5$ ) can be polymerized into a variety of discrete polynuclear anionic clusters or extended architectures via Te–O–Te bridges.

## Introduction

Noncentrosymmetric (NCS) compounds exhibit many interesting and useful properties such as ferroelectricity, piezoelectricity, and second-order nonlinear optical (NLO) behavior.<sup>1</sup> With inorganic materials, the macroscopic acentricity is often a manifestation of the asymmetric coordination environments of the cations. One of the important classes of NCS compounds is based on cations susceptible to second-order Jahn–Teller (SOJT) distortion.<sup>2</sup> Such a type of distortion can occur in two different types of cations,  $d^0$  transition metals (TMs; Ti<sup>4+</sup>, V<sup>5+</sup>, Nb<sup>5+</sup>, Mo<sup>6+</sup>, W<sup>6+</sup>, etc.) and cations with stereoactive lone pairs (Se<sup>4+</sup>, Te<sup>4+</sup>, Sb<sup>3+</sup>, etc.), both in asymmetric coordination environments. With the octahedrally coordinated  $d^0$  TMs, SOJT effects occur when the empty d orbitals of the metal mix with the filled p orbitals of the ligands. In extended structures, this mixing results in a host of nearly degenerate electronic configurations that can be removed through the spontaneous distortion of

the  $d^0$  TM.<sup>2</sup> The  $d^0$  TM cation can be distorted toward either a face (local  $C_3$  direction), an edge (local  $C_2$  direction), or a corner (local  $C_4$  direction) of the  $MO_6$  octahedron. The situation with the lone-pair cations is more complex. The structural distortion and polarization was thought to be through the mixing of the metal cation s and p orbitals. Recently, it is believed that the oxide anion also plays an important role in the lone-pair formation. The interaction of the s and p orbitals of the metal cation with the oxide anion p states is critical for lone-pair formation. No matter how the lone pair is created, its structural consequences are profound because the lone pair “pushes” the oxide ligands toward one side of the cation, resulting in a highly asymmetric coordination environment.<sup>3</sup> Studies have shown that compounds containing both types of cations may have a large second-harmonic-generation (SHG) efficiency due to the “constructive” addition of these polarizations, which will be discussed in more detail later.

Tetrahedral groups such as silicates, phosphates, and germanates are very important building units in zeolites and other porous materials that have been widely used as

(3) (a) Porter, Y.; Bhuvanesh, N. S. P.; Halasyamani, P. S. *Inorg. Chem.* **2001**, *40*, 1172. (b) Porter, Y.; Ok, K. M.; Bhuvanesh, N. S. P.; Halasyamani, P. S. *Chem. Mater.* **2001**, *13*, 1910. (c) Ok, K. M.; Bhuvanesh, N. S. P.; Halasyamani, P. S. *Inorg. Chem.* **2001**, *40*, 1978.

catalysts.<sup>4</sup> Some of phosphates such as KDP ( $\text{KH}_2\text{PO}_4$ ) and KTP ( $\text{KTiOPO}_4$ ) are also very important second-order NLO materials.<sup>5</sup> Therefore, the combination of these tetrahedral groups with the lone pair containing a  $\text{Te}^{\text{IV}}$  or  $\text{Se}^{\text{IV}}$  cation may also result in new inorganic compounds with novel structural topologies and SHG properties.

It should also pointed out that the transition-metal oxyhalides of  $\text{Se}^{\text{IV}}$  or  $\text{Te}^{\text{IV}}$  display many types of novel structures and interesting magnetic properties such as low-dimensional magnets, etc. Transition-metal tellurium(IV) or selenium(IV) oxyhalides can be regarded as “chemical scissors”. The later TM cations form bonds to both oxygen and halide, while lone-pair cations tend to form bonds only to oxygen anions. This chemical difference can be utilized to reduce the dimensionality of the TM arrangements with interesting magnetic properties.<sup>6</sup> It is amazing that many compounds in above systems can be generally formulated as  $\text{M}_{n+1}(\text{QO}_3)_n\text{X}_2$ , where M, Q, and X represent the TM, Se (or Te), and the halide anion, respectively. Our exploration of the missing members in the nickel system afforded four new compounds, namely,  $\text{Ni}_{n+1}(\text{QO}_3)_n\text{X}_2$  (Q = Se, X = Cl, Br,  $n = 4$ ; Q = Te, X = Cl,  $n = 6$  and 10).<sup>7</sup> We also prepared two new cadmium(II) tellurium(IV) oxychlorides, namely,  $\{\text{Cd}_2(\text{Te}_6\text{O}_{13})\}\{\text{Cd}_2\text{Cl}_6\}$  and  $\text{Cd}_7\text{Cl}_8(\text{Te}_7\text{O}_{17})$ , which display several unusual structural building units: two new types of 1D tellurium(IV) oxide anions ( $\text{Te}_6\text{O}_{13}^{2-}$  and  $\text{Te}_7\text{O}_{17}^{6-}$ ) (Scheme 1), 1D  $\text{Cd}_2\text{Cl}_6$  double chains, and 2D  $\text{Cd}_7\text{Cl}_8$  sheets.<sup>8</sup> We also obtained a series of lanthanide transition-metal tellurium(IV) oxyhalides with three different types of structures, namely,  $\text{DyCuTe}_2\text{O}_6\text{Cl}$ ,  $\text{ErCuTe}_2\text{O}_6\text{Cl}$ ,  $\text{ErCuTe}_2\text{O}_6\text{Br}$ ,  $\text{Sm}_2\text{Mn}(\text{Te}_5\text{O}_{13})\text{Cl}_2$ ,  $\text{Dy}_2\text{Cu}(\text{Te}_5\text{O}_{13})\text{Br}_2$ , and  $\text{Nd}_4\text{Cu}(\text{TeO}_3)_5\text{Cl}_3$ .<sup>9</sup> The halide anion may be involved in metal coordination or remain isolated.

In this paper, our discussion will be focused on only two important systems: combination of  $\text{Te}^{\text{IV}}$  or  $\text{Se}^{\text{IV}}$  with  $d^0$  TMs or with the tetrahedral groups of main-group elements such as  $\text{SiO}_4$ ,  $\text{GeO}_4$ ,  $\text{BO}_4$ ,  $\text{PO}_4$ , etc. Our group and many other groups have been exploring new NCS compounds in these two systems during the past few years (Table 1). Of course, other  $\text{Te}^{\text{IV}}$  or  $\text{Se}^{\text{IV}}$  compounds are also very important; for

**Scheme 1.** Selected Examples of Tellurium(IV) Oxide Anions with Polynuclear Cluster Units or Extended Structures

example, several good SHG materials have been discovered in compounds with two types of lone-pair cations.<sup>3</sup>

## Part I. Combination of $d^0$ TM Ions with $\text{Se}^{\text{IV}}$ or $\text{Te}^{\text{IV}}$

**1. Alkali (or Alkaline Earth)– $d^0$  TM– $\text{Se}^{\text{IV}}$  (or  $\text{Te}^{\text{IV}}$ )–O System.** This system contains a large number of compounds, some of which possess good SHG properties (Table 1). The TM ions with the  $d^0$  electronic configuration are mostly  $\text{Mo}^{6+}$  and  $\text{W}^{6+}$ , but there are also some examples involving  $\text{V}^{5+}$ ,  $\text{Nb}^{5+}$ , and  $\text{Ta}^{5+}$ .

Five compounds with four different structural types were reported in alkali-metal–molybdenum(VI) selenium(IV) oxide systems  $\text{A}_2\text{MoSeO}_6$  (A =  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Rb}^+$ ) and  $\text{A}_2(\text{MoO}_3)_3(\text{SeO}_3)$  (A =  $\text{NH}_4^+$ ,  $\text{Cs}^+$ ).<sup>10</sup> The first three compounds feature a 3D anionic network, a 0D anionic dimer, and a 1D anionic chain, respectively. The 3D anionic structure of  $\text{Na}_2\text{MoSeO}_6$  (NCS space group  $P2_13$ ) is based on alternative linkages of  $\text{MoO}_6$  octahedra (distorted toward a face) and  $\text{SeO}_3$  groups, forming tunnels of  $\text{Mo}_2\text{Se}_2$  four-membered rings and  $\text{Mo}_4\text{Se}_4$  eight-membered rings; the sodium cations occupy the larger tunnels.  $\text{Na}_2\text{MoSeO}_6$  revealed a weak SHG intensity of about  $10 \times \text{SiO}_2$ . The structure of  $\text{K}_2\text{MoSeO}_6$  contains two edge-sharing  $\text{MoO}_6$  octahedra, each of which is further chelated by a  $\text{SeO}_3$  group, forming  $[\text{Mo}_2\text{Se}_2\text{O}_{12}]^{4-}$  clusters that are separated by  $\text{K}^+$  ions.

In Rb<sub>2</sub>MoSeO<sub>6</sub>, the MoO<sub>6</sub> octahedra are interconnected into a 1D chain via corner-sharing, the SeO<sub>3</sub> groups are hanging on both sides of the chain, and each of them shares an edge with a MoO<sub>6</sub> octahedron.<sup>10a</sup> The last two compounds (space group *P6<sub>3</sub>*) are isostructural and feature a 2D hexagonal tungsten bronzelike anionic layer of MoO<sub>6</sub> octahedra capped on one side by pyramidally coordinated Se<sup>IV</sup>;<sup>10b</sup> such a layer was also reported in Cs<sub>2</sub>(MoO<sub>3</sub>)<sub>3</sub>(TeO<sub>3</sub>) and A<sub>2</sub>(WO<sub>3</sub>)<sub>3</sub>(TeO<sub>3</sub>) (A = Rb, Cs).<sup>11b,12c</sup>

Compounds with three different structural types have been reported in alkali–Mo<sup>6+</sup>–Te<sup>4+</sup>–O systems.<sup>11</sup> Na<sub>2</sub>Mo<sub>3</sub>Te<sub>3</sub>O<sub>16</sub> in NCS space group *I2* exhibits a quasi-1D crystal structure, with each chain consisting of Mo<sub>3</sub>O<sub>14</sub> trimers (composed of three edge-shared MoO<sub>6</sub> octahedra) that are connected to Te<sub>3</sub>O<sub>8</sub><sup>4-</sup> anions (formed by one TeO<sub>4</sub> group corner-sharing with two TeO<sub>3</sub> groups). Both of the Mo<sup>6+</sup> and Te<sup>4+</sup> cations are in the asymmetric coordination environments attributable to SOJT effects. The Mo<sup>6+</sup> cations are distorted toward an edge of the MoO<sub>6</sub> octahedron (local *C*<sub>2</sub> direction). The SHG efficiency of Na<sub>2</sub>Mo<sub>3</sub>Te<sub>3</sub>O<sub>16</sub> is approximately 500 × α-SiO<sub>2</sub> and is phase-matchable. The strong SHG efficiency is maintained up to the melting temperature (around 450 °C).<sup>11a</sup> The use of other alkali-metal ions led to two other structural types.<sup>11b</sup> A<sub>2</sub>Mo<sub>3</sub>TeO<sub>12</sub> (A = NH<sub>4</sub>, Cs) with noncentrosymmetric space group *P6<sub>3</sub>* contain 2D hexagonal tungsten oxide related (Mo<sub>3</sub>TeO<sub>12</sub>)<sup>2-</sup> anionic layers interleaved with NH<sub>4</sub><sup>+</sup>/Cs<sup>+</sup> ions. The TeO<sub>3</sub> groups cap on the same side of the anionic layer. A<sub>4</sub>Mo<sub>6</sub>Te<sub>2</sub>O<sub>24</sub>·6H<sub>2</sub>O (A = Rb, K) is composed of discrete centrosymmetric (Mo<sub>6</sub>Te<sub>2</sub>O<sub>24</sub>)<sup>4-</sup> anionic aggregates and alkali-metal ions. In this hexamolybdoditellurite anion, the Mo<sub>6</sub>O<sub>24</sub> flat hexagonal ring, formed by edge-

sharing of six MoO<sub>6</sub> octahedra, is capped by tellurium on both sides. Isolated Mo<sub>6</sub>O<sub>18</sub> and Mo<sub>5</sub>O<sub>15</sub> cyclic clusters capped by SeO<sub>3</sub> groups were also reported with amines as template cations.<sup>13</sup> The Mo<sup>6+</sup> ions are distorted toward a face of the MoO<sub>6</sub> octahedron in A<sub>2</sub>Mo<sub>3</sub>TeO<sub>12</sub> (A = NH<sub>4</sub><sup>+</sup>, Cs<sup>+</sup>), whereas they are distorted toward an edge in A<sub>4</sub>Mo<sub>6</sub>Te<sub>2</sub>O<sub>24</sub>·6H<sub>2</sub>O (A = Rb<sup>+</sup>, K<sup>+</sup>). The Te<sup>4+</sup> cations in both types of compounds adopt the same asymmetric coordination environments and are bonded to three O atoms.

Three types of compounds were found in the alkali–Te<sup>IV</sup>–W<sup>VI</sup>–O systems, namely, (NH<sub>4</sub>)<sub>2</sub>WTe<sub>2</sub>O<sub>8</sub>, Na<sub>2</sub>W<sub>2</sub>TeO<sub>9</sub>, and A<sub>2</sub>W<sub>3</sub>TeO<sub>12</sub> (A = K<sup>+</sup>, Rb<sup>+</sup>, Cs<sup>+</sup>).<sup>12</sup> (NH<sub>4</sub>)<sub>2</sub>WTe<sub>2</sub>O<sub>8</sub> crystallizes in the noncentrosymmetric (NCS) polar space group *P2<sub>1</sub>* (No. 4). It exhibits a 2D structure consisting of WO<sub>6</sub> octahedra connected to TeO<sub>4</sub> polyhedra; the ammonium cations are located at the interlayer region. Both W<sup>6+</sup> and Te<sup>4+</sup> cations are in asymmetric coordination environments attributable to SOJT effects. The WO<sub>6</sub> octahedron exhibits three short and three long W–O bonds. (NH<sub>4</sub>)<sub>2</sub>WTe<sub>2</sub>O<sub>8</sub> revealed a moderate SHG efficiency of approximately 250 × α-SiO<sub>2</sub>.<sup>12a</sup> The noncentrosymmetric Na<sub>2</sub>W<sub>2</sub>TeO<sub>9</sub> (space group *Ia*) exhibits a 3D structure comprising distorted WO<sub>6</sub> octahedra linked to asymmetric TeO<sub>3</sub> groups. The WO<sub>6</sub> octahedra form a corrugated 2D tungsten oxide layer through corner-sharing; these layers are further interconnected by TeO<sub>3</sub> groups. Both Te<sup>IV</sup> and W<sup>VI</sup> cations are in local acentric environments attributable to SOJT effects. Powder SHG measurements on polycrystalline Na<sub>2</sub>W<sub>2</sub>TeO<sub>9</sub> indicated a strong SHG intensity of approximately 500 × SiO<sub>2</sub>, and the material is phase-matchable (type I).<sup>12b</sup> Cs<sub>2</sub>W<sub>3</sub>TeO<sub>12</sub> is isostructural with Cs<sub>2</sub>Mo<sub>3</sub>TeO<sub>12</sub>.<sup>11b</sup> Although K<sub>2</sub>W<sub>3</sub>TeO<sub>12</sub> and Rb<sub>2</sub>W<sub>3</sub>TeO<sub>12</sub> have chemical formulas similar to that of Cs<sub>2</sub>W<sub>3</sub>TeO<sub>12</sub>, their structures are somehow different. All three compounds contain the same

2D tungsten oxide layer of corner-sharing  $\text{WO}_6$  octahedra with  $\text{W}_3$  and  $\text{W}_6$  rings. The  $\text{TeO}_3$  groups in  $\text{K}_2\text{W}_3\text{TeO}_{12}$  act as interlayer linkers to form a 3D structure. In Rb and Cs compounds, the  $\text{TeO}_3$  groups only cap on the same side of the  $\text{W}_3$  rings; therefore, the compounds are 2D. The K compound is centrosymmetric, whereas the Rb and Cs compounds are acentric and revealed strong SHG efficiencies of 200 and  $400 \times \text{SiO}_2$ , respectively. These can be explained by the different radii of the alkali-metal ions; the larger one will have larger interlayer  $\text{O}\cdots\text{O}$  separations, which allows a similar capping of  $\text{TeO}_3$  groups and the formation of noncentrosymmetric structures.<sup>12c</sup>

The  $\text{AE}^{2+}\text{—Mo}^{6+}(\text{W}^{6+})\text{—Se}^{4+}(\text{Te}^{4+})\text{—O}$  systems are still less explored.<sup>14</sup> Two compounds in the Ba—Mo—Se—O system were reported,  $\text{BaMoO}_3(\text{SeO}_3)$  and  $\text{BaMo}_2\text{O}_5(\text{SeO}_3)_2$ .  $\text{BaMoO}_3(\text{SeO}_3)$  exhibits a layered structure in which  $\text{MoO}_6$  octahedra (distorted toward a face) are bridged by  $\text{SeO}_3$  groups, forming  $\text{Mo}_2\text{Se}_2$  four-membered rings and  $\text{Mo}_3\text{Se}_3$  six-membered rings.  $\text{BaMo}_2\text{O}_5(\text{SeO}_3)_2$  is acentric ( $Cmc2_1$ ) and features a 3D network composed of pairs of corner-sharing  $\text{MoO}_6$  octahedra bridged by  $\text{SeO}_3$  groups. The  $\text{MoO}_6$  octahedron is distorted toward an edge (the local  $C_2$  direction).<sup>14a</sup>  $\text{BaMo}_2\text{TeO}_9$  and  $\text{BaW}_2\text{TeO}_9$  are isostructural and crystallized in the polar space group  $P2_1$ ; their structures feature an anionic layer composed of  $\text{MO}_6$  octahedra linked to the asymmetric  $\text{TeO}_3$  polyhedra. The  $\text{MoO}_6$  octahedra in  $\text{BaMo}_2\text{TeO}_9$  are distorted toward a face (along the local  $C_3$  [111] direction) with three short and three long Mo—O distances. The  $\text{WO}_6$  octahedra in  $\text{BaW}_2\text{TeO}_9$  exhibit two types of distortion: toward a face as discussed above and toward an edge with two short, two normal, and two long W—O bonds. Two  $\text{MO}_6$  octahedra form a dimer via a M—O—M bridge and such dimeric units are further interconnected by  $\text{TeO}_3$  groups via M—O—Te bridges.  $\text{BaMo}_2\text{TeO}_9$  and  $\text{BaW}_2\text{TeO}_9$  revealed extremely strong SHG responses of 600 and  $500 \times \text{SiO}_2$ , respectively.<sup>14b</sup>

Several phases were reported in  $\text{A—V}^{5+}\text{—Se}^{4+}\text{—O}$  systems:  $\text{AVSeO}_5$  ( $\text{A} = \text{Rb}, \text{Cs}$ ),  $\text{A}(\text{VO}_2)_3(\text{SeO}_3)_2$  ( $\text{A} = \text{K}^+, \text{Rb}^+, \text{Cs}^+, \text{NH}_4^+$ ), and the  $\text{V}^{5+}/\text{V}^{4+}$  mixed-valent  $\text{KV}_2\text{SeO}_7$ .<sup>15</sup>  $\text{A}(\text{VO}_2)_3(\text{SeO}_3)_2$  ( $\text{A} = \text{K}^+, \text{Rb}^+, \text{Cs}^+, \text{NH}_4^+$ ) are isostructural with  $\text{A}_2(\text{MoO}_3)_3(\text{SeO}_3)_2$  ( $\text{A} = \text{NH}_4^+, \text{Cs}^+$ ),<sup>10b</sup> featuring hexagonal layers of corner-sharing  $\text{VO}_6$  octahedra, with the  $\text{SeO}_3$  groups capping on one side of the vanadium(V) oxide layer; the interlayer distances are much shorter than those of the corresponding Mo compounds because of the much fewer cations needed to balance the charge.<sup>15a,b</sup> The structure of the polar  $\text{AVSeO}_5$  ( $\text{A} = \text{Rb}, \text{Cs}$ ; space group  $P2_1$ ) is a 3D anionic network formed by alternative linkages of  $\text{VO}_5$  square pyramids and  $\text{SeO}_3$  groups via corner-sharing, creating two types of helical tunnels along the  $b$  axis composed of four- and eight-membered rings. The alkali-metal ions occupy the large tunnels.<sup>15b</sup>  $\text{KV}_2\text{SeO}_7$  contains both  $\text{V}^{5+}$  and

$\text{V}^{4+}$  ions, in octahedral and tetrahedral coordination environments, respectively. Its structure features a double layer of  $\{\text{V}_2\text{SeO}_7\}^-$  composed of corner-sharing  $\text{VO}_6$  octahedra,  $\text{VO}_4$  tetrahedra, and  $\text{SeO}_3$  groups.<sup>15c</sup>

Only one compound was reported for the alkaline earth— $\text{V}^{\text{V}}\text{—Se}^{\text{IV}}\text{—O}$  family.  $\text{Ba}_{2.5}(\text{VO}_2)_3(\text{SeO}_3)_4 \cdot \text{H}_2\text{O}$  exhibits a 2D-layered structure consisting of layers of  $\text{VO}_5$  square pyramids linked to  $\text{SeO}_3$  polyhedra, with the  $\text{Ba}^{2+}$  cations and water molecules occupying the interlayer region.<sup>16</sup> Each layer consists of eclipsed 12-membered  $\text{V}_6\text{Se}_6$  rings and smaller eight-membered  $\text{V}_4\text{Se}_4$  rings. Each  $\text{V}^{5+}$  is bonded to five O atoms in a distorted square-pyramidal environment with two “short” [1.642(9) and 1.647(9) Å] and three “normal” bonds [1.952(8)—2.006(9) Å]. Three of the five O atoms are further bonded to  $\text{Se}^{4+}$  cations, whereas the two “short” V—O bonds remain terminal. The selenite groups adopt two types of binding modes: tridentate bridging with three Se—O—V bridges and bidentate with only two Se—O—V bridges.

Reports on  $\text{A}(\text{Ae})\text{—Nb}^{5+}$  (or  $\text{Ta}^{5+})\text{—Se}^{4+}$  (or  $\text{Te}^{4+})\text{—O}$  systems are still rare.<sup>17</sup> The structural backbone of  $\text{Na}_{1.4}\text{Nb}_3\text{Te}_{4.9}\text{O}_{18}$  may be considered as two sets of corner-shared  $\text{NbO}_6$  octahedral chains. The “first” chain consists of one row of corner-shared  $\text{NbO}_6$  octahedra that are linked by  $\text{TeO}_3$  and  $\text{TeO}_4$  polyhedra, whereas the “second” chain consists of two rows of corner-shared  $\text{NbO}_6$  octahedra that are linked by  $\text{TeO}_3$  groups. Each of these chains of octahedra runs parallel to the [010] direction. The “first” and “second” chains are linked by the  $\text{TeO}_3$  and  $\text{TeO}_4$  groups, along the [100] and [010] directions, resulting in the 3D topology. The  $\text{Te}^{4+}$  cation that connects the two chains is partially occupied. The  $\text{Na}^+$  cations reside in the spaces between the two chains. The second compound,  $\text{NaNb}_3\text{Te}_4\text{O}_{16}$ , also exhibits a 3D structure consisting of corner-linked  $\text{NbO}_6$  octahedra that are connected to asymmetric  $\text{TeO}_3$  and  $\text{TeO}_4$  groups. Similar to  $\text{Na}_{1.4}\text{Nb}_3\text{Te}_{4.9}\text{O}_{18}$ , the structural backbone of  $\text{NaNb}_3\text{Te}_4\text{O}_{16}$  may also be considered as an infinite chain of corner-shared  $\text{NbO}_6$  octahedra. The chain consists of three corner-shared  $\text{NbO}_6$  octahedra running along the [001] direction. These octahedra are infinite, through additional corner-sharing, in the [010] direction. The  $\text{TeO}_3$  and  $\text{TeO}_4$  groups serve to link these  $\text{NbO}_6$  octahedra. The  $\text{Na}^+$  cations reside in the spaces between the  $\text{NbO}_6$  octahedra. In both compounds, the distortion of the  $\text{NbO}_6$  octahedron is along the local  $C_4$  direction.<sup>17a</sup> The crystal structures of  $\text{Ba}_2\text{M}_6\text{Te}_2\text{O}_{21}$  ( $\text{M} = \text{Nb}, \text{Ta}$ ) are dominated by the  $[\text{M}_6\text{O}_{21}]^{12-}$  anionic network with incorporated  $\text{Ba}^{2+}$  and  $\text{Te}^{4+}$  ions. Tunnels based on  $\text{M}_4$ ,  $\text{M}_3\text{Te}$  and  $\text{M}_6\text{Te}_2$  rings are formed along the [010] direction; the  $\text{Ba}^{2+}$  ions occupy the tunnels of eight-membered rings.<sup>17b</sup>

**2. Ln— $d^0$  TM— $\text{Te}^{\text{IV}}$  or  $\text{Se}^{\text{IV}}\text{—O}$  Systems.** Only three compounds, namely,  $\text{LaNbTeO}_6$  and  $\text{La}_4\text{M}_2\text{Te}_6\text{O}_{23}$  ( $\text{M} = \text{Nb}, \text{Ta}$ ), were reported by the Halasyamani group before our group’s work on this research field.<sup>18</sup>  $\text{LaNbTeO}_6$  consists of 1D corner-linked chains of  $\text{NbO}_6$  octahedra that are

connected by  $\text{TeO}_3$  polyhedra.  $\text{La}_4\text{M}_2\text{Te}_6\text{O}_{23}$  ( $\text{M} = \text{Nb}, \text{Ta}$ ) also has a 1D crystal structure, consisting of different types of chains that run parallel to the  $c$  axis. One chain consists of corner-linked  $\text{MO}_6$  octahedra. Each  $\text{MO}_6$  octahedron shares additional corners with  $\text{TeO}_3$  and  $\text{TeO}_4$  groups. The  $\text{TeO}_3$  polyhedra are separated from each other, but the  $\text{TeO}_4$  groups are connected through an O atom into the  $\text{TeO}_4$  “chain”, which is broken at random intervals because of the defects on the bridging O atoms. The other chain is the isolated  $\text{TeO}_4$  chain that is also broken at random intervals because of the defects. In all three compounds, the  $\text{Nb}^{5+}$  or  $\text{Ta}^{5+}$  cation is distorted toward an edge with two “short”, two “normal”, and two long  $\text{M}^{5+}-\text{O}$  bonds; the short ones are terminal and the long ones are connected to a  $\text{Te}^{4+}$  cation, whereas the remaining two bonds are involved in the  $\text{M}^{5+}-\text{O}-\text{M}^{5+}$  bridges. In all three compounds,  $\text{Te}^{4+}$  cation is in an asymmetric coordination environment attributable to its stereoactive lone pair.

We think that a slight change of the radius of the  $\text{Ln}^{\text{III}}$  ion may induce a completely different structure; in other words, the “lanthanide contraction” may play an important role in the structures formed. Furthermore, lanthanide compounds are capable of emitting strong luminescence in the visible and near-IR regions; both oxyanions of  $d^0$  TM and  $\text{Te}^{\text{IV}}$  (or  $\text{Se}^{\text{IV}}$ ) are good activators for luminescence of the  $\text{Ln}^{\text{III}}$  ions. Like corresponding alkali or alkaline-earth compounds,  $\text{Ln}^{\text{III}}$  compounds with NCS structures may also be formed. Therefore, systematic investigation of the lanthanide selenium(IV) or tellurium(IV) oxides with additional TM ions with a  $d^0$  electronic configuration may give rise to new lanthanide NLO materials or luminescent materials. Solid-state reactions of lanthanide(III) oxide (and/or lanthanide(III) oxychloride),  $\text{MoO}_3$  (or  $\text{WO}_3$ ) and  $\text{TeO}_2$  at high temperature led to 12 new compounds with 8 different types of structures, namely,  $\text{Nd}_2\text{MoSe}_2\text{O}_{10}$ ,  $\text{Gd}_2\text{MoSe}_3\text{O}_{12}$ ,  $\text{La}_2\text{MoTe}_3\text{O}_{12}$ ,  $\text{Nd}_2\text{MoTe}_3\text{O}_{12}$ ,  $\text{Ln}_2\text{MoTe}_4\text{O}_{14}$  ( $\text{Ln} = \text{Pr}, \text{Nd}$ ),  $\text{La}_2\text{WTe}_6\text{O}_{18}$ ,  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$ , and  $\text{Ln}_5\text{MTe}_7\text{O}_{23}\text{Cl}_3$  ( $\text{Ln} = \text{Pr}, \text{Nd}$ ;  $\text{M} = \text{Mo}, \text{W}$ ).<sup>19</sup>

$\text{Nd}_2\text{MoSe}_2\text{O}_{10}$  can also be formulated as  $\text{Nd}_2(\text{MoO}_4)(\text{SeO}_3)_2$ . Its structure features a 3D network in which the  $\text{Nd}^{\text{III}}$  ions are interconnected by  $\text{SeO}_3^{2-}$  anions and  $\text{MoO}_4$  tetrahedra (Figure 1). Both Nd1 and Nd2 are eight-coordinated by eight O atoms with Nd–O distances in the range of 2.407(7)–2.540(7) Å. The  $\text{Mo}^{\text{VI}}$  atom is in a slightly distorted tetrahedral coordination environment with Mo–O distances in the range of 1.740(7)–1.816(6) Å. The interconnection of Nd1 atoms via bridging selenite groups leads to a  $\langle 001 \rangle$  layer, whereas Nd2 atoms are bridged by  $\text{MoO}_4$  tetrahedra to form a  $\langle 002 \rangle$  layer. The above two types of layers are further interconnected via Nd–O–Se bridges into a 3D network (Figure 1). The lone pairs of the  $\text{Se}^{\text{IV}}$  cations are oriented toward the cavities of the structure.

When the molar ratio of Se/Ln was increased to 3:2,  $\text{Gd}_2\text{MoSe}_3\text{O}_{12}$  with a different structure was obtained.

**Figure 1.** View of the structure of  $\text{Nd}_2\text{MoSe}_2\text{O}_{10}$  down the  $a$  axis. The  $\text{MoO}_4$  tetrahedra are shaded in cyan. Nd, Se, and O atoms are drawn as green, yellow, and red circles, respectively.

**Figure 2.** View of the structure of  $\text{Gd}_2\text{MoSe}_3\text{O}_{12}$  down the  $b$  axis. The  $\text{MoO}_6$  tetrahedra are shaded in cyan. Gd, Se, and O atoms are drawn as green, yellow, and red circles, respectively.

$\text{Gd}_2\text{MoSe}_3\text{O}_{12}$  can also be formulated as  $\text{Gd}_2(\text{MoO}_3)(\text{SeO}_3)_3$ , which can be considered as one  $\text{O}^{2-}$  anion of  $\text{Nd}_2\text{MoSe}_2\text{O}_{10}$  being replaced by the third selenite group. The structure of  $\text{Gd}_2\text{MoSe}_3\text{O}_{12}$  features a 3D network of gadolinium(III) selenite, with the  $\text{MoO}_6$  octahedra occupying the cavities of the network. Both Gd atoms in the asymmetric unit are eight-coordinated, with Gd–O distances ranging from 2.337(5) to 2.485(5) Å. Unlike that in  $\text{Nd}_2\text{MoSe}_2\text{O}_{10}$ , the  $\text{Mo}^{\text{VI}}$  atom in  $\text{Gd}_2\text{MoSe}_3\text{O}_{12}$  is octahedrally coordinated by three O atoms from three selenite groups and three  $\text{O}^{2-}$  anions (Figure 2). The  $\text{MoO}_6$  octahedron is distorted toward a face (local  $C_3$  direction), exhibiting three “long” and three “short” Mo–O bonds. The magnitude of the distortion ( $\Delta_d$ ) is 1.492. The interconnection of the  $\text{Gd}^{\text{III}}$  ions by selenite groups results in a 3D network with tunnels running along the  $b$  axis. The  $\text{MoO}_6$  octahedra are located at the tunnels formed by gadolinium(III) selenite (Figure 2).

The structure of  $\text{La}_2\text{MoTe}_3\text{O}_{12}$  is composed of two  $\text{La}^{3+}$  ions, one  $\text{MoO}_4^{2-}$  anion, and one  $\text{Te}_3\text{O}_8^{4-}$  anion. It can be considered as two selenite groups in  $\text{Nd}_2\text{MoSe}_2\text{O}_{10}$  being replaced by a  $\text{Te}_3\text{O}_8^{4-}$  anion. The  $\text{La}^{3+}$  ion is nine-coordinated by seven O atoms from four  $\text{Te}_3\text{O}_8^{4-}$  anions and

(18) Ok, K. M.; Zhang, L.; Halasyamani, P. S. *J. Solid State Chem.* **2003**, *175*, 264.

(19) (a) Shen, Y. L.; Jiang, H. L.; Xu, J.; Mao, J. G.; Cheah, K. W. *Inorg. Chem.* **2005**, *44*, 9314. (b) Jiang, H. L.; Ma, E.; Mao, J. G. *Inorg. Chem.* **2007**, *46*, 7012.

**Figure 3.** View of the structure of  $\text{La}_2\text{MoO}_4(\text{Te}_3\text{O}_8)$  down the  $a$  axis. The  $\text{MoO}_4$  tetrahedra are shaded in cyan. La, Te, and O atoms are drawn as green, yellow, and red circles, respectively.

two O atoms from two  $\text{MoO}_4^{2-}$  anions. The La–O distances range from 2.451(8) to 2.821(8) Å. The trinuclear  $\text{Te}_3\text{O}_8^{4-}$  anion is formed by one  $\text{TeO}_4$  group corner-sharing with two  $\text{TeO}_3$  groups. The  $\text{Mo}^{\text{VI}}$  cation is in a slightly distorted tetrahedral coordination geometry, with the Mo–O distances ranging from 1.754(8) to 1.793(11) Å. The interconnection of the  $\text{La}^{3+}$  by chelating and bridging  $\text{Te}_3\text{O}_8^{4-}$  anions led to a 3D network with tunnels along the  $a$  axis. These tunnels are formed by 10-membered rings (six La and four Te). The  $\text{MoO}_4$  polyhedra are located at the above tunnels and connected with the  $\text{La}^{3+}$  ions via corner-sharing (Figure 3).

$\text{Nd}_2\text{MoTe}_3\text{O}_{12}$  can be formulated as  $\text{Nd}_2(\text{MoO}_4)(\text{TeO}_3)(\text{Te}_2\text{O}_5)$ ; it can also be considered as the  $\text{Te}_3\text{O}_8^{4-}$  anion in  $\text{La}_2\text{MoTe}_3\text{O}_{12}$  being replaced by a tellurite and a ditellurite group. Different from the  $\text{La}^{3+}$  ion in  $\text{La}_2\text{MoO}_4(\text{Te}_3\text{O}_8)$ , the  $\text{Nd}^{\text{III}}$  ion in  $\text{Nd}_2(\text{MoO}_4)(\text{TeO}_3)(\text{Te}_2\text{O}_5)$  is eight-coordinated by eight O atoms, with the Nd–O distances in the range of 2.324(4)–2.603(4) Å. The  $\text{Te}^{\text{IV}}$  cations of the tellurite and ditellurite groups are coordinated by three O atoms in an asymmetric environment. The Te–O distances are in the range of 1.838(4)–1.987(2) Å. The interconnection of  $\text{Nd}^{\text{III}}$  ions by bridging tellurite and ditellurite groups afforded a layered architecture (Figure 4). The  $\text{MoO}_4$  tetrahedron was capped on four  $\text{Nd}^{\text{III}}$  ions of the 2D layer with the terminal O1 atom toward the interlayer space (Figure 4). The interlayer distance is about 8.85 Å.<sup>19a</sup>

The use of more  $\text{TeO}_2$  in the syntheses led to  $\text{Ln}_2\text{MoTe}_4\text{O}_{14}$  (Ln = Pr, Nd). Both compounds are isostructural and feature a 3D network in which the  $\text{Ln}^{\text{III}}$  ions are interconnected by 1D  $\text{Te}_4\text{O}_{10}^{4-}$  chains and  $\text{MoO}_4$  tetrahedra (Figure 5). Therefore,  $\text{Ln}_2\text{MoTe}_4\text{O}_{14}$  (Ln = Pr, Nd) can also be formulated as  $\text{Ln}_2(\text{MoO}_4)(\text{Te}_4\text{O}_{10})$  (Ln = Pr, Nd). Among two unique  $\text{Ln}^{\text{III}}$  atoms in the asymmetric unit, one is eight-coordinated by eight tellurite O atoms whereas the other is eight-coordinated by six tellurite O atoms and two O atoms from two molybdate anions. The  $\text{Mo}^{\text{VI}}$  atom is in a slightly distorted tetrahedral coordination environment with Mo–O

**Figure 4.** View of the structure of  $\text{Nd}_2(\text{MoO}_4)(\text{TeO}_3)(\text{Te}_2\text{O}_5)$  down the  $c$  axis. The  $\text{MoO}_4$  tetrahedra are shaded in cyan. Nd, Te, and O atoms are drawn as green, yellow, and red circles, respectively.

**Figure 5.** View of the structure of  $\text{Ln}_2\text{MoTe}_4\text{O}_{14}$  down  $a$ -axis. The  $\text{MoO}_4$  tetrahedra are shaded in cyan. Ln, Te, and O atoms are drawn as green, yellow, and red circles, respectively.

distances in the range of 1.733(4)–1.779(4) Å. The  $\text{Te}^{\text{IV}}$  atoms are three- or four-coordinated by O atoms in an asymmetric environment. The Te–O distances are in the range of 1.826(3)–2.457(3) Å. The  $\text{TeO}_3$  and  $\text{TeO}_4$  groups are interconnected via corner-sharing into a novel 1D  $\text{Te}_4\text{O}_{10}^{4-}$  anionic chain (Scheme 1). The interconnection of Nd1 and Nd2 atoms via bridging  $\text{Te}_4\text{O}_{10}^{4-}$  anionic chains led to neodymium(III) tellurium(IV) oxide layers, which are further interconnected by  $\text{MoO}_4$  tetrahedra into a 3D network with apertures along the  $a$  axis. The aperture is formed by 10-membered rings containing six  $\text{Ln}^{\text{III}}$  ions, two  $\text{MoO}_4^{2-}$  anions, and two  $\text{TeO}_4$  groups. The lone pairs of the  $\text{Te}^{\text{IV}}$  atoms are oriented toward the apertures of the structure (Figure 5). It is worth comparing the structures of  $\text{Ln}_2\text{MoTe}_4\text{O}_{14}$  (Ln = Pr, Nd) with those of  $\text{La}_2\text{MoTe}_3\text{O}_{12}$  and  $\text{Nd}_2\text{MoTe}_3\text{O}_{12}$ . All four compounds contain  $\text{MoO}_4$  tetrahedra; however, their Te–O architectures are completely different:  $\text{La}_2\text{MoTe}_3\text{O}_{12}$  features discrete  $\text{Te}_3\text{O}_8^{4-}$  anions, whereas  $\text{Nd}_2\text{MoTe}_3\text{O}_{12}$  contains both  $\text{TeO}_3^{2-}$  and dimeric  $\text{Te}_2\text{O}_5^{2-}$  anions, and 1D  $\text{Te}_4\text{O}_{10}^{4-}$  anions are formed in  $\text{Ln}_2\text{MoTe}_4\text{O}_{14}$  (Ln = Pr, Nd).  $\text{Nd}_2\text{MoTe}_3\text{O}_{12}$  features a layered structure with  $\text{MoO}_4$  tetrahedra hanging between two

**Figure 6.** View of the structure of  $\text{La}_2\text{WTe}_6\text{O}_{18}$  down the  $a$  axis. The  $\text{WO}_4$  tetrahedra are shaded in cyan. La, Te, and O atoms are drawn as green, yellow, and red circles, respectively.

neighboring layers, whereas the  $\text{MoO}_4$  tetrahedra in  $\text{La}_2\text{MoTe}_3\text{O}_{12}$  are located at the tunnels of lanthanum(III) tellurium(IV) oxide. In  $\text{Ln}_2\text{MoTe}_4\text{O}_{14}$  ( $\text{Ln} = \text{Pr}, \text{Nd}$ ), the  $\text{MoO}_4$  tetrahedron serves as a bridge between two lanthanide(III) tellurium(IV) oxide layers.

The above synthetic methods were also applied to the  $\text{Ln}^{\text{III}}-\text{W}^{\text{VI}}-\text{Te}^{\text{IV}}-\text{O}$  systems.  $\text{La}_2\text{WTe}_6\text{O}_{18}$  was obtained when we attempted to prepare the  $\text{W}^{\text{VI}}$  analogue of  $\text{La}_2\text{MoTe}_3\text{O}_{12}$ .  $\text{La}_2\text{WTe}_6\text{O}_{18}$  can also be formulated as  $\text{La}_2(\text{WO}_4)(\text{Te}_3\text{O}_7)_2$ . The La atom is 10-coordinated by seven O atoms from two  $\text{Te}_3\text{O}_7^{2-}$  anions and three O atoms from three  $\text{WO}_4$  tetrahedra. The La–O distances range from 2.487(4) to 2.884(8) Å. The  $\text{W}^{\text{VI}}$  atom is tetrahedrally coordinated by four O atoms, with the W–O distances ranging from 1.724(6) to 1.786(1) Å. The  $\text{Te}^{\text{IV}}$  atom is coordinated by four O atoms with Te–O distances in the range of 1.850(4)–2.193(1) Å. The  $\text{TeO}_4$  groups are interconnected into a  $\text{Te}_3\text{O}_7^{2-}$  layer via corner-sharing (Scheme 1). Within the layer, three-membered rings and “pear-shaped” six-membered rings are found. Similar  $\text{Te}_3$  and “pear-shaped”  $\text{Te}_6$  rings have been reported in  $\text{Cd}_7\text{Cl}_8(\text{Te}_7\text{O}_{17})$ .<sup>8</sup> The interconnection of  $\text{La}^{3+}$  ions by bridging  $\text{WO}_4^{2-}$  anions led to a 2D  $[\text{La}_2\text{WO}_4]^{4+}$  layer along the  $ab$  plane. One  $[\text{La}_2\text{WO}_4]^{4+}$  layer and two  $\text{Te}_3\text{O}_7^{2-}$  layers are further interconnected into a thick layer in the  $ab$  plane via La–O–Te bridges (Figure 6). The thickness of the layer is about 7.65 Å, and the interlayer opening width is about 3.0 Å. This type of layer can also be viewed as the  $[\text{La}_2\text{WO}_4]^{4+}$  layer being sandwiched between two  $\text{Te}_3\text{O}_7^{2-}$  anionic layers. The lone-pair electrons of  $\text{Te}^{\text{IV}}$  atoms are oriented toward the interlayer space (Figure 6).

$\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$  with a different structure was obtained in our attempts to prepare the  $\text{Nd}^{\text{III}}$  analogue of  $\text{La}_2\text{WTe}_6\text{O}_{18}$ .  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$  features a 3D network structure in which the  $\text{W}_2\text{O}_{10}$  dimers occupy the large apertures formed by neodymium tellurite (Figure 7). Among two unique  $\text{Nd}^{3+}$  ions in the asymmetric unit, one is eight-coordinated whereas the other one is nine-coordinated. The Nd–O distances range from 2.333(5) to 2.681(5) Å. Unlike that in  $\text{La}_2\text{WTe}_6\text{O}_{18}$ , both of the  $\text{W}^{\text{VI}}$  cations in  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$  are octahedrally coordinated. W1 is coordinated by two O atoms from two tellurite groups and four terminal O atoms, whereas W2 is coordinated by one O atom from a tellurite group and five

**Figure 7.** View of the structure of  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$  down the  $a$  axis. The  $\text{WO}_4$  tetrahedra are shaded in cyan. Nd, Te, and O atoms are drawn as green, yellow, and red circles, respectively.

terminal O atoms. A pair of  $\text{WO}_6$  octahedra is interconnected via edge-sharing into a  $\text{W}_2\text{O}_{10}^{8-}$  dimer. Both of the  $\text{WO}_6$  octahedra are severely distorted. The W1 atom is distorted toward a face (local  $C_3$  direction) with three “short” [1.743(6)–1.834(5) Å] and three “long” [2.033(5)–2.300(5) Å] W–O bonds, whereas the W2 atom is distorted toward an edge ( $C_2$ ) with two “short” [1.747(5) and 1.767(5) Å], two “normal” [1.900(5) and 1.930(5) Å], and two “long” [2.172(5) and 2.232(5) Å] W–O bonds. Again both  $\text{W}^{\text{VI}}$  cations are distorted away from the O atoms that bonded to the  $\text{Te}^{4+}$  cations. The magnitudes of the distortion ( $\Delta_d$ ) are 1.118 and 0.945 Å respectively for  $\text{W}1\text{O}_6$  and  $\text{W}2\text{O}_6$ . The interconnection of the  $\text{Nd}^{\text{III}}$  ions by the tellurite groups resulted in a 3D network with two types of apertures along the  $a$  axis (Figure 7). The large apertures with a narrow-long shape are formed by 10-membered rings composed by four  $\text{TeO}_3$  groups and six  $\text{Nd}^{\text{III}}$  ions, and the small ones are formed by four-membered rings composed of two Nd1 and two  $\text{Te}1\text{O}_3$  groups. The  $\text{W}_2\text{O}_{10}$  dimers are located at the large apertures (Figure 7). In  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$ , each  $\text{W}_2\text{O}_{10}$  dimer connects with two  $\text{TeO}_3$  groups (one in a unidentate fashion, and the other in a bidentate bridging fashion) to form a  $[\text{W}_2\text{Te}_2\text{O}_{13}]^{6-}$  anion. Therefore, the structure of  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$  also can be viewed as the  $\text{Nd}^{3+}$  ions being interconnected by  $[\text{W}_2\text{Te}_2\text{O}_{13}]^{6-}$  anions via Nd–O–Te and Nd–O–W bridges (Figure 7).

When chloride anion was introduced into the Ln–Mo (W)–Te–O system, isostructural  $\text{Ln}_5\text{MTe}_7\text{O}_{23}\text{Cl}_3$  ( $\text{Ln} = \text{Pr}, \text{Nd}; \text{M} = \text{Mo}, \text{W}$ ) were obtained. These compounds feature a 3D network of a lanthanide(III) molybdenum(VI) tellurium(IV) oxychloride with large apertures occupied by isolated Cl anions and the lone-pair electrons of  $\text{Te}^{\text{IV}}$  (Figure 8).  $\text{Ln}_5\text{MTe}_7\text{O}_{23}\text{Cl}_3$  can also be formulated as  $\text{Ln}_5(\text{MO}_4)-(\text{Te}_5\text{O}_{13})(\text{TeO}_3)_2\text{Cl}_3$ . The asymmetric unit of  $\text{Ln}_5\text{MoTe}_7\text{O}_{23}\text{Cl}_3$  contains three unique Ln<sup>III</sup> ions, one M<sup>VI</sup> cation, and four Te atoms. Two Ln<sup>III</sup> ions are 8-coordinated, whereas the third one is 10-coordinated. The Ln–Cl distances are significantly longer than those of the Ln–O bonds. The M<sup>VI</sup> cation is in

**Figure 8.** View of the structure of  $\text{Nd}_5\text{MoTe}_7\text{O}_{23}\text{Cl}_3$  down the  $a$  axis. The  $\text{MoO}_4$  tetrahedra are shaded in cyan. Nd, Te, Cl, and O atoms are drawn as green, yellow, pink, and red circles, respectively.

a distorted tetrahedral coordination environment with Mo–O distances in the range of 1.714(10)–1.845(9) Å. Te1, Te3, and Te4 are three-coordinated by three O atoms, whereas Te2 is four-coordinated. Two  $\text{TeIO}_3$  groups, two  $\text{Te}_2\text{O}_4$  groups, and a  $\text{Te}_3\text{O}_3$  group are corner-sharing to form a novel  $\text{Te}_5\text{O}_{13}^{6-}$  pentamer in a “semicycle” shape. The Te–O distances fall in the range of 1.845(8)–2.162(6) Å. The interconnection of  $\text{Nd}^{\text{III}}$  ions via  $\text{Te}_5\text{O}_{13}^{6-}$  and  $\text{TeO}_3^{2-}$  anions resulted in a thick layer parallel to the  $ab$  plane. Neighboring lanthanide tellurium(IV) oxide layers are bridged by Cl2 atoms into a complicated 3D network, forming two different types of apertures (Figure 8). The  $\text{MO}_4$  polyhedra are capped on both sides of the  $\text{Ln}_4\text{O}_2\text{Cl}_2$  rings. The isolated Cl anions and the lone-pair electrons of  $\text{Te}^{\text{IV}}$  atoms of the  $\text{Te}_5\text{O}_{13}^{6-}$  groups occupy the large apertures formed by eight-membered rings (Figure 8).

The solid-state luminescent properties of  $\text{Nd}_2\text{MoSe}_2\text{O}_{10}$ ,  $\text{Nd}_2\text{MoTe}_3\text{O}_{12}$ ,  $\text{Nd}_2\text{MoTe}_4\text{O}_{14}$ , and  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$  were investigated at both room temperature and 10 K, and the solid-state luminescent properties of  $\text{Nd}_5\text{MoTe}_7\text{O}_{23}\text{Cl}_3$  and  $\text{Nd}_5\text{WTe}_7\text{O}_{23}\text{Cl}_3$  were studied at room temperature. Under excitation at 514 nm, the room temperature emission spectra for all six  $\text{Nd}^{\text{III}}$  compounds display three sets of characteristic emission bands for the  $\text{Nd}^{\text{III}}$  ion in the near-IR region:  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{9/2}$ ,  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{11/2}$ , and  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{13/2}$ .  $\text{Nd}_2\text{MoTe}_3\text{O}_{12}$  contains only one independent  $\text{Nd}^{\text{III}}$  site, whereas  $\text{Nd}_2\text{MoSe}_2\text{O}_{10}$ ,  $\text{Nd}_2\text{MoTe}_4\text{O}_{14}$ , and  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$  each contain two unique  $\text{Nd}^{\text{III}}$  sites with  $C_1$  symmetry. Because of the crystal-field effect, each transition band is expected to be split into several subbands. The  ${}^4\text{F}_{3/2}$  is expected to split into two sublevels, whereas the complete degeneracy of  ${}^4\text{I}_{9/2}$ ,  ${}^4\text{I}_{11/2}$ , and  ${}^4\text{I}_{13/2}$  leads to five, six, and seven sublevels, respectively. Therefore,  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{9/2}$ ,  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{11/2}$ , and  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{13/2}$  transitions will have a maximum of 10, 12, and 14 subbands if both the lower and upper levels of  ${}^4\text{F}_{3/2}$  are populated as in the case of room temperature. When two

and more unique  $\text{Nd}^{\text{III}}$  sites are present such as  $\text{Nd}_2\text{MoSe}_2\text{O}_{10}$ ,  $\text{Nd}_2\text{MoTe}_4\text{O}_{14}$ , and  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$ , the spectrum will be even more complicated. Because of the overlapping of some emission bands and resolution limit of the instruments, the observed emission peaks are usually fewer than that expected. At very low temperature such as 10 K, only the lower level of  ${}^4\text{F}_{3/2}$  is populated; hence, the corresponding emission spectra are much simpler. Also the  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{11/2}$  transition, subbands are difficult to be resolved even at 10 K. The low-temperature emission spectrum for  $\text{Nd}_2\text{MoTe}_3\text{O}_{12}$  displays five and six subbands for the  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{9/2}$  and  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{11/2}$  transitions, respectively, which is in good agreement with the theoretical expectation. Assuming the energy of the lowest sublevel of  ${}^4\text{I}_{9/2}$  is  $0\text{ cm}^{-1}$ , the energies of the lower level of  ${}^4\text{F}_{3/2}$  and the other four sublevels for  ${}^4\text{I}_{9/2}$  are calculated. Likewise, we can calculate the energies for the six sublevels of  ${}^4\text{I}_{11/2}$ . Upon excitation at 580 nm, both  $\text{Nd}_2\text{MoSe}_2\text{O}_{10}$  and  $\text{Nd}_2\text{MoTe}_4\text{O}_{14}$  display 8 and 10 subbands for the  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{9/2}$  and  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{11/2}$  transitions at 10 K, whereas  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$  displays eight and nine subbands at 10 K upon excitation at 288 nm. The lifetimes for the  ${}^4\text{F}_{3/2} \rightarrow {}^4\text{I}_{11/2}$  transition were measured to be 0.21 and 0.20 ms and 3.2 and 3.6  $\mu\text{s}$  respectively for  $\text{Nd}_2\text{MoSe}_2\text{O}_{10}$  and  $\text{Nd}_2\text{MoTe}_3\text{O}_{12}$  and for  $\text{Nd}_2\text{MoTe}_4\text{O}_{14}$  and  $\text{Nd}_2\text{W}_2\text{Te}_2\text{O}_{13}$ . The three  $\text{Pr}^{\text{III}}$  compounds are capable of emitting luminescent light in the blue, green, and red regions.  $\text{Pr}_5\text{MoTe}_7\text{O}_{23}\text{Cl}_3$  and  $\text{Pr}_5\text{WTe}_7\text{O}_{23}\text{Cl}_3$  display four sets of emission bands at 491 nm (very strong,  ${}^3\text{P}_0 \rightarrow {}^3\text{H}_4$ ), 534 nm (moderate,  ${}^3\text{P}_0 \rightarrow {}^3\text{H}_5$ ), 619 nm (moderate,  ${}^3\text{P}_0 \rightarrow {}^3\text{H}_6$ ), 649 nm (strong,  ${}^3\text{P}_0 \rightarrow {}^3\text{F}_2$ ), and 735 nm (weak,  ${}^3\text{P}_0 \rightarrow {}^3\text{F}_4$ ) under  $\lambda_{\text{ex}} = 448\text{ nm}$ . Under the same experimental conditions, the corresponding emission bands for  $\text{Pr}_2\text{MoTe}_4\text{O}_{14}$  are much weaker. Because of the so-called “crystal-field effect” as well as multiple  $\text{Pr}^{3+}$  sites, a few transition bands were split into several subbands.<sup>19</sup>

**3. TM–d<sup>0</sup> TM–Te<sup>IV</sup> or Se<sup>IV</sup>–O Systems.** Reports on compounds in the TM– $\text{Mo}^{\text{V}}$ – $\text{Te}^{\text{IV}}$ / $\text{Se}^{\text{IV}}$ –O systems are much fewer than those of the alkali and alkaline-earth ones.<sup>20</sup> The structure of  $\text{Cd}(\text{VO}_2)_4(\text{SeO}_3)_3 \cdot \text{H}_2\text{O}$  can be described as a pillared layered architecture. The layer is composed of dimers of  $\text{VO}_5$  square pyramids and dimers of  $\text{CdO}_7$  decahedra connected to one another by sharing corner and/or edge O atoms, whereas the pillars are composed of distorted  $\text{VO}_6$  octahedra connected to one another via corner- and edge-sharing with capping selenite groups; the lone-pair electrons of the  $\text{Se}^{\text{IV}}$  atoms are oriented toward the long-narrow-shaped tunnels along the  $b$  axis.

We deem that the combination of the lone-pair electrons of  $\text{Se}^{\text{IV}}$  or  $\text{Te}^{\text{IV}}$  with the distorted  $\text{MO}_6$  octahedron may lead to new compounds in TM– $\text{Mo}^{\text{VI}}$  or  $\text{V}^{\text{V}}$ – $\text{Se}^{\text{IV}}$ / $\text{Te}^{\text{IV}}$ –O systems with novel structures and unusual physical properties, such as magnetic or optical properties. So far, no nickel molybdenum(VI) selenite or tellurite has been structurally characterized. Our exploration of new phases in nickel

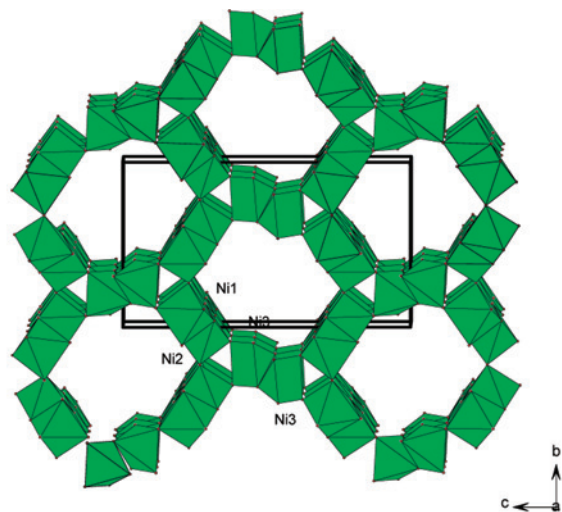

**Figure 9.**  $[\text{Mo}_4\text{O}_{16}]^{8-}$  tetranuclear cluster unit (a) and  $[\text{Ni}_6\text{O}_{22}]^{32-}$  hexanuclear cluster unit in  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{SeO}_3)$  (b), and 1D  $[\text{Ni}_3\text{O}_{11}]^{16-}$  corrugated chain along the  $b$  axis in  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{TeO}_3)$  (c).

molybdenum(VI) selenite or tellurite systems led to three new compounds, namely,  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{XO}_3)$  ( $X = \text{Se}, \text{Te}$ )<sup>21</sup> and  $\text{Ni}_3(\text{MoO}_4)(\text{TeO}_3)_2$ .<sup>22</sup>

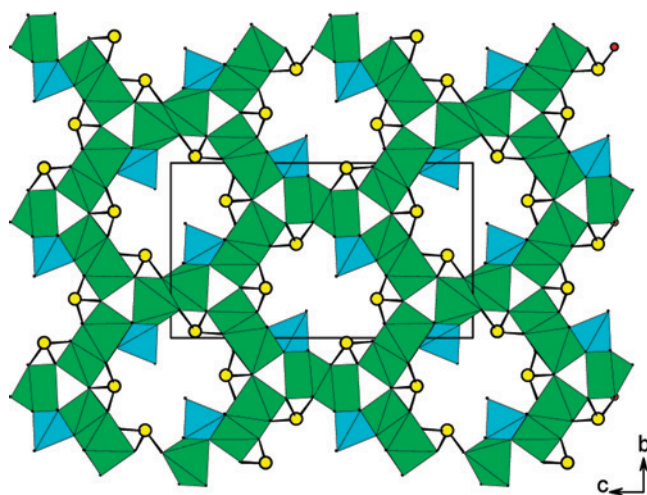

$\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{XO}_3)$  ( $X = \text{Se}, \text{Te}$ ) display two different types of 3D structures containing  $[\text{Mo}_4\text{O}_{16}]^{8-}$  and  $[\text{Ni}_6\text{O}_{22}]^{32-}$  clusters or 1D nickel oxide chains (Figure 9). The structure of  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{SeO}_3)$  features a 3D network in which  $[\text{Ni}_6\text{O}_{22}]^{32-}$  cluster units are interconnected by  $[\text{Mo}_4\text{O}_{16}]^{8-}$  clusters and  $\text{SeO}_3^{2-}$  anions. All three  $\text{Ni}^{\text{II}}$  ions in the asymmetric unit are octahedrally coordinated by six O atoms, with Ni–O distances ranging from 1.983(4) to 2.160(4) Å. Both  $\text{Mo}^{\text{VI}}$  cations are octahedrally coordinated by six O atoms. The Mo–O bond distances are in the range of 1.719(4)–2.304(4) Å. The  $\text{Mo}^{\text{VI}}$  cations are distorted toward an edge (local  $C_2$  direction) with two “short”, two “normal”, and two “long”  $\text{Mo}^{6+}$ –O bonds. The magnitudes of the distortions ( $\Delta_d$ ) were calculated to be 1.18 and 1.29 Å respectively for Mo1 and Mo2. The four  $\text{Mo}^{\text{VI}}\text{O}_6$  octahedra are interconnected by edge-sharing to form a cyclic  $[\text{Mo}_4\text{O}_{16}]^{8-}$  tetranuclear cluster unit (Figure 9a). Six  $\text{NiO}_6$  octahedra are interconnected into a hexanuclear  $[\text{Ni}_6\text{O}_{22}]^{32-}$  cluster unit through edge-sharing (Figure 9b). The intracuster  $\text{Ni}\cdots\text{Ni}$  separations between a pair of edge-sharing  $\text{NiO}_6$  octahedra are in the range of 3.034(1)–3.245(1) Å (Figure 9b). The  $[\text{Ni}_6\text{O}_{22}]^{32-}$  cluster units are bridged by  $\text{SeO}_3^{2-}$  groups to form a 2D nickel selenite layer parallel to the  $ab$  plane. Neighboring nickel selenite layers are further interconnected by the  $[\text{Mo}_4\text{O}_{16}]^{8-}$  clusters via Mo–O–Ni bridges into a 3D network structure. The lone-pair electrons of the

$\text{Se}^{\text{IV}}$  atoms are oriented toward the cavities of the structure. The structure of  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{TeO}_3)$  is different from that of  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{SeO}_3)$ , although their chemical formulas are comparable. It features a 3D structure in which the corrugated nickel oxide anionic chains are bridged by  $[\text{Mo}_4\text{O}_{16}]^{8-}$  cluster units and  $\text{TeO}_3^{2-}$  anions. As in  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{SeO}_3)$ , the  $\text{Ni}^{\text{II}}$  and  $\text{Mo}^{\text{VI}}$  cations are octahedrally coordinated by six O atoms. Similar to that in  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{SeO}_3)$ , the four  $\text{Mo}^{\text{VI}}\text{O}_6$  octahedra in  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{TeO}_3)$  are interconnected via edge-sharing to form a  $[\text{Mo}_4\text{O}_{16}]^{8-}$  tetranuclear cluster unit. Two  $\text{Ni}_1\text{O}_6$  and one  $\text{Ni}_2\text{O}_6$  octahedra are interconnected via edge-sharing into a  $[\text{Ni}_3\text{O}_{13}]^{20-}$  trinuclear unit. Such neighboring trinuclear units are further interconnected through edge-sharing into a corrugated  $[\text{Ni}_3\text{O}_{11}]^{16-}$  anionic chain along the  $b$  axis with a Ni1–O2–Ni1 bond angle of 84.65(9)° (Figure 9c). This nickel oxide chain can also be viewed as  $\text{Ni}_2\text{O}_6$  octahedra being grafted onto the corrugated chain of  $\text{Ni}_1\text{O}_6$  through edge-sharing. It is interesting to note that  $[\text{Ni}_6\text{O}_{22}]^{32-}$  clusters are formed in  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{SeO}_3)$ , whereas corrugated  $[\text{Ni}_3\text{O}_{11}]^{16-}$  anionic chains are observed in  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{TeO}_3)$ . Both nickel oxide building units are based on  $\text{Ni}_3\text{O}$  triangles. The  $\text{Ni}_3\text{O}$  triangles in  $[\text{Ni}_6\text{O}_{22}]^{32-}$  clusters are condensed via sharing Ni–Ni edges, whereas those in  $[\text{Ni}_3\text{O}_{11}]^{16-}$  anionic chains are interconnected through pairs of Ni–O–Ni bridges. These different nickel(II) oxide architectures may result from the different coordination modes of the selenite and tellurite groups as well as the different ionic radii of  $\text{Se}^{\text{IV}}$  and  $\text{Te}^{\text{IV}}$ . Neighboring corrugated nickel(II) oxide chains are bridged by  $\text{TeO}_3^{2-}$  anions to form a thick nickel(II) tellurite layer parallel to the  $ab$  plane. The

**Figure 10.** 3D network of nickel(II) oxide in  $\text{Ni}_3(\text{MoO}_4)(\text{TeO}_3)_2$  (a) and view of the structure of  $\text{Ni}_3(\text{MoO}_4)(\text{TeO}_3)_2$  along the  $a$  axis. The  $\text{NiO}_6$  and  $\text{NiO}_5$  polyhedra are shaded in green, and  $\text{MoO}_4$  tetrahedra are shaded in cyan. Te atoms are drawn as yellow circles.

thickness of the layer is about 12.1 Å. Such layers are further interconnected by the  $[\text{Mo}_4\text{O}_{16}]^{8-}$  clusters via Mo–O–Ni bridges into a 3D network structure. The lone-pair electrons of the  $\text{Te}^{\text{IV}}$  atoms are oriented toward the tunnels of the structure.

When we increased the molar ratio of  $\text{TeO}_2/\text{MoO}_3$  to 2:1, a new Ni–Mo–Te–O phase with NCS structure (space group  $P2_12_12_1$ ),  $\text{Ni}_3(\text{MoO}_4)(\text{TeO}_3)_2$ , was obtained recently.<sup>22</sup> Its structure features a novel 3D network of nickel(II) oxide with larger 1D tunnels along the  $a$  axis. The  $\text{MoO}_4$  tetrahedra and  $\text{TeO}_3$  groups cap the walls of the tunnels (Figure 10). Among three unique  $\text{Ni}^{\text{II}}$  ions in the asymmetric unit, two are octahedrally coordinated, whereas the third one is in a square-pyramidal geometry.  $\text{NiO}_6$  octahedra are intercon-

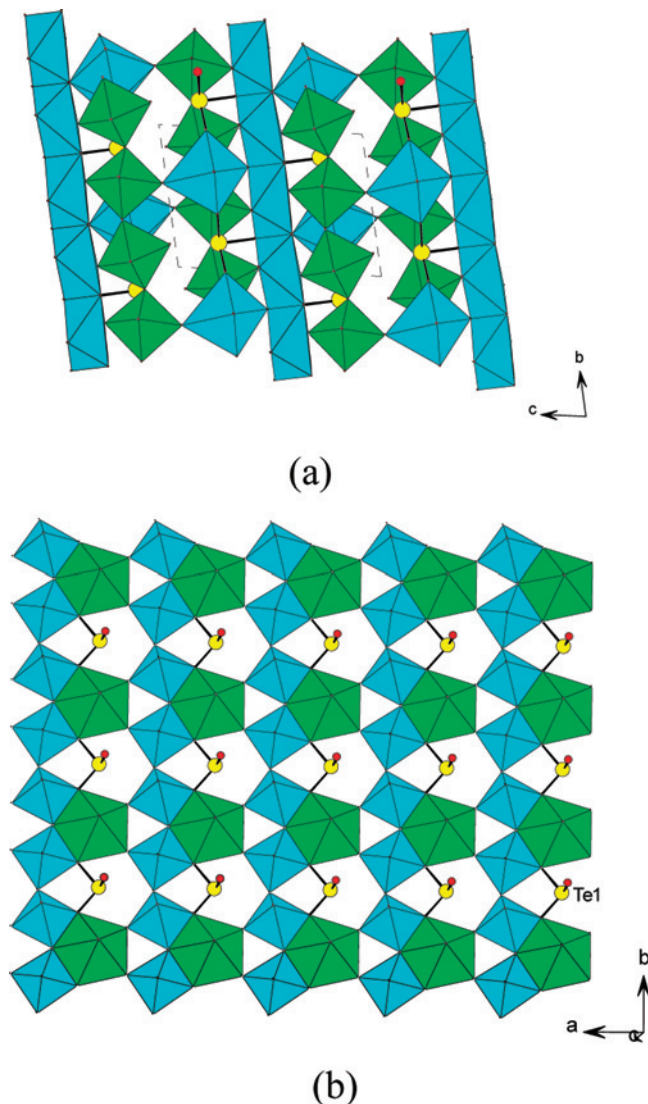

**Figure 11.** View of the structure of  $\text{Cd}_4\text{V}_2\text{Te}_3\text{O}_{15}$  down the  $a$  axis. The  $\text{CdO}_6$  and  $\text{VO}_4$  polyhedra are shaded in blue and green, respectively. Te and O atoms are drawn as yellow and red circles, respectively.

**Figure 12.** View of the structure of  $\text{Cd}_6\text{V}_2\text{Se}_5\text{O}_{21}$  down the  $b$  axis. The  $\text{CdO}_6$ ,  $\text{CdO}_7$  and  $\text{CdO}_8$  polyhedra are shaded in cyan and  $\text{VO}_4$  tetrahedra in green. Se and O atoms are drawn as pink and red circles, respectively.

nected by edge-sharing along the  $a$  axis into a 1D chain, whereas  $\text{NiO}_5$  polyhedra are corner-sharing along the  $a$  axis into a 1D chain. These two types of chains are further interconnected via corner-sharing into a 3D open framework of nickel oxide, forming 1D helical tunnels along the  $a$  axis, which are based on  $\text{Ni}_{12}$  rings (Figure 10a). Unlike those in  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{SeO}_3)$  and  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{TeO}_3)$ , the  $\text{Mo}^{\text{VI}}$  cation is in a tetrahedral environment and there are no Mo–O–Mo or Mo–O–Te bridges. The  $\text{MoO}_4$  tetrahedra and  $\text{TeO}_3$  groups cap walls of the tunnels; the lone-pair electrons of  $\text{Te}^{\text{IV}}$  cations and terminal O atoms of the  $\text{MoO}_4$  tetrahedra are pointing toward the center of the tunnel (Figure 10b). SHG measurements indicate that its SHG signal is very weak.

Both  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{SeO}_3)$  and  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{TeO}_3)$  obey the Curie–Weiss law above 60 K with Weiss constants ( $\theta$ ) of 15.4(2) and 5.5(1) K respectively for Se and Te compounds, indicating significant ferromagnetic interactions between

**Figure 13.** View of the structure of CdWTeO<sub>6</sub> down the *a* axis (a) and a 2D layer composed of CdO<sub>6</sub>, WO<sub>6</sub>, and TeO<sub>3</sub> groups (b). The CdO<sub>6</sub> and CdO<sub>7</sub> polyhedra are shaded in green and the WO<sub>6</sub> octahedra in green. Te and O atoms are drawn as yellow and red circles, respectively.

magnetic centers. It is expected that the magnetic interactions should be dominated by the magnetic interactions between Ni<sup>II</sup> ions within the hexanuclear [Ni<sub>6</sub>O<sub>22</sub>]<sup>32-</sup> cluster in Ni<sub>3</sub>(Mo<sub>2</sub>O<sub>8</sub>)(SeO<sub>3</sub>) and the 1D [Ni<sub>3</sub>O<sub>11</sub>]<sup>16-</sup> anionic chain in Ni<sub>3</sub>(Mo<sub>2</sub>O<sub>8</sub>)(TeO<sub>3</sub>). Long-range magnetic ordering is observed below 28 and 56 K.

We also extended our studies to TM ions with a d<sup>10</sup> electronic configuration such as Zn<sup>II</sup> and Cd<sup>II</sup> ions.<sup>23</sup> Zn<sup>II</sup> or Cd<sup>II</sup> compounds may display semiconducting properties, and they are also able to emit blue light. Solid-state reactions of zinc(II) or cadmium(II) oxide, V<sub>2</sub>O<sub>5</sub> and TeO<sub>2</sub>, at high temperature lead to two novel quaternary compounds, namely, Zn<sub>3</sub>V<sub>2</sub>TeO<sub>10</sub> and Cd<sub>4</sub>V<sub>2</sub>Te<sub>3</sub>O<sub>15</sub>.<sup>23</sup> Very recently Cd<sub>6</sub>(V<sub>2</sub>O<sub>6</sub>)(SeO<sub>3</sub>)<sub>5</sub> and CdWTeO<sub>6</sub> were also isolated.<sup>24</sup>

The structure of Zn<sub>3</sub>V<sub>2</sub>TeO<sub>10</sub> is a complicated 3D network constructed by the interconnection of ZnO<sub>5</sub>, ZnO<sub>6</sub>, VO<sub>4</sub>, and

**Figure 14.** View of the structure of Se<sub>2</sub>B<sub>2</sub>O<sub>7</sub> down the *b* axis. BO<sub>4</sub> tetrahedra are shaded in cyan. Se, B, and O atoms are drawn as yellow, cyan, and red circles, respectively.

TeO<sub>4</sub> polyhedra via corner- and edge-sharing. Cd<sub>4</sub>V<sub>2</sub>Te<sub>3</sub>O<sub>15</sub> with an acentric structure features a 3D network in which the cadmium tellurite layers are further interconnected by both “isolated” VO<sub>4</sub> tetrahedra and 1D vanadium oxide helical chains (Figure 11). Cd<sub>4</sub>V<sub>2</sub>Te<sub>3</sub>O<sub>15</sub> displays a SHG efficiency of about 1.4 times that of KDP. It is stable up to 840 °C and shows little absorption in 0.6–10.0 μm. Luminescent measurements indicate that both compounds exhibit broad emission bands in the blue-light region.<sup>23</sup>

Cd<sub>6</sub>V<sub>2</sub>Se<sub>5</sub>O<sub>21</sub> was obtained by solid-state reactions of cadmium(II) oxide, V<sub>2</sub>O<sub>5</sub> and SeO<sub>2</sub>. Its structure is composed of a 3D open framework of cadmium(II) selenite and 1D vanadium(V) oxide chains of corner-sharing VO<sub>4</sub> tetrahedra. The vanadium(V) oxide chains are inserted at the large tunnels of cadmium(II) selenite via V–O–Cd bridges. The Cd<sup>II</sup> ions are coordinated by six, seven, or eight O atoms (Figure 12).<sup>24a</sup> CdWTeO<sub>6</sub> crystallized in triclinic *P* $\bar{1}$ ; its structure features a complicated 3D network of corner/edge-sharing CdO<sub>6</sub> octahedra, CdO<sub>7</sub> pentagonal bipyramids, WO<sub>6</sub> octahedra, and TeO<sub>3</sub> groups (Figure 13). There are three Cd<sup>II</sup>, two W<sup>VI</sup>, and two Te<sup>IV</sup> sites in its asymmetric unit. Two Cd<sup>II</sup> sites lying on the center of symmetry are octahedrally coordinated, and the third Cd<sup>II</sup> ion in a general position is seven-coordinated in a pentagonal-bipyramidal geometry. The CdO<sub>6</sub> octahedra form 1D chains along the *b* axis via edge-sharing; these 1D chains are capped by TeO<sub>3</sub> groups. The WO<sub>6</sub> octahedra are distorted toward a face (local C<sub>3</sub> direction). Neighboring WO<sub>6</sub> octahedra are interconnected via corner-sharing into 1D chains also along the *b* axis. These tungsten oxide chains are further capped by TeO<sub>3</sub> groups on one side, and they are further bridged by CdO<sub>7</sub> polyhedra via edge- and corner-sharing into a 2D layer parallel to the *ab* plane (Figure 13b). Two such layers are interconnected into a double layer via Cd–O–W bridges. The above two types of building units are alternating and interconnected along the *c* axis via corner-sharing (Te–O–Cd, Cd–O–W, and Cd–O–Cd bridges) into a 3D architecture (Figure 13a).<sup>24b</sup>

## Part II. Metal Tellurites and Selenites Containing Tetrahedral Groups of Main-Group Elements

So far such compounds are still rare. With respect to tellurite phosphate oxides, a few materials have been reported, namely,  $\text{Te}_2\text{O}_3(\text{HPO}_4)$ ,  $\text{Te}_8\text{O}_{10}(\text{PO}_4)_4$ ,  $\text{Ba}_2\text{TeO}(\text{PO}_4)_2$ ,  $\text{BaTeMo}_4(\text{PO}_4)$  ( $M = \text{Nb}^{5+}$  or  $\text{Ta}^{5+}$ ), and  $\text{A}_2\text{TeMo}_2\text{O}_6(\text{PO}_4)_2$  ( $A = \text{K}, \text{Rb}, \text{Cs}, \text{Tl}$ ).<sup>25</sup> Structurally these materials are different;  $\text{BaNbTeO}_4(\text{PO}_4)$  contains 2D layers, whereas  $\text{Te}_2\text{O}_3(\text{HPO}_4)$  and  $\text{Te}_8\text{O}_{10}(\text{PO}_4)_4$  exhibit 3D structures consisting of asymmetric  $\text{TeO}_4$  and  $\text{TeO}_5$  polyhedra that are linked through corner-sharing.<sup>25a-c</sup>  $\text{Ba}_2\text{TeO}(\text{PO}_4)_2$  displays a novel 1D chain structure that is composed of  $\text{PO}_4$  tetrahedra and  $\text{TeO}_5$  polyhedra.  $\text{Te}^{4+}$  cations are in asymmetric coordination environments attributable to their lone pairs. Two  $\text{TeO}_5$  polyhedra form a dimeric unit via edge-sharing; two neighboring  $\text{Te}_2\text{O}_8$  units are further interconnected via a pair of phosphate groups into a 1D chain along the  $b$  axis, and each  $\text{Te}^{\text{IV}}$  atom is also bonded to the third phosphate group through one  $\text{Te}-\text{O}-\text{P}$  bridge.<sup>25d</sup> The isostructural mixed-metal phosphates,  $\text{BaMTeO}_4(\text{PO}_4)$  ( $M = \text{Nb}^{5+}, \text{Ta}^{5+}$ ), have novel layered crystal structures consisting of  $\text{M}^{\text{V}}\text{O}_6$  corner-sharing octahedral chains that are connected to  $\text{Te}^{\text{IV}}\text{O}_4$  polyhedra and phosphate tetrahedra. The phosphate groups act as pendent groups between two neighboring layers. The  $\text{Nb}^{5+}$  cation distorts along the local  $C_4$  direction of its octahedron with a “short–long–short–long”  $\text{Nb}-\text{O}-\text{Nb}$  bond motif. Furthermore, the  $\text{Nb}^{5+}$  cation displaces away from the oxide ligands that are bonded to  $\text{Te}^{4+}$  or  $\text{P}^{5+}$  cations, attributable to the structural rigidity of the  $\text{TeO}_4$  and  $\text{PO}_4$  polyhedra.<sup>25e</sup>  $\text{A}_2\text{Mo}_2\text{TeO}_6(\text{PO}_4)_2$  displays a pillared layered architecture composed of  $\text{Mo}_2\text{P}_2\text{O}_{14}$  layers and  $\text{TeO}_4$  groups as the pillars. Within the  $\text{Mo}_2\text{P}_2\text{O}_{14}$  layer, the  $\text{MoO}_6$  octahedra (distorted toward an edge) and  $\text{PO}_4$  tetrahedra are interconnected via corner-sharing, forming  $\text{Mo}_2\text{P}_2$  four-membered rings and  $\text{Mo}_4\text{P}_4$  eight-membered rings.<sup>25f</sup>

So far, there is no reports on metal selenites or tellurites containing additional  $\text{SiO}_4$  or  $\text{GeO}_4$  tetrahedra. Our exploration into the unexplored  $\text{RE}-\text{Ge}/\text{Si}-\text{Te}^{\text{IV}}-\text{O}$  systems afforded two novel lanthanum(III) tellurites with additional  $\text{SiO}_4$  or  $\text{GeO}_4$  tetrahedra, namely,  $\text{La}_4(\text{Si}_{5.2}\text{Ge}_{2.8}\text{O}_{18})(\text{TeO}_3)_4$  and  $\text{La}_2(\text{Si}_6\text{O}_{13})(\text{TeO}_3)_2$ .<sup>26</sup>

The structure of  $\text{La}_4(\text{Si}_{5.2}\text{Ge}_{2.8}\text{O}_{18})(\text{TeO}_3)_4$  features a 3D network composed of the  $[(\text{Si}_{5.2}\text{Ge}_{2.8}\text{O}_{18})]^{4-}$  tetrahedral layers and the  $[\text{La}_4(\text{TeO}_3)_4]^{4+}$  layers that alternate along the  $b$  axis. The germanate–silicate layer consists of corner-sharing  $\text{XO}_4$  ( $X = \text{Si}, \text{Ge}$ ) tetrahedra, forming four- and six-membered rings. The structure of  $\text{La}_2(\text{Si}_6\text{O}_{13})(\text{TeO}_3)_2$  is a 3D network composed of the  $[\text{Si}_6\text{O}_{13}]^{2-}$  double layers and the  $[\text{La}_2(\text{TeO}_3)_2]^{2+}$  layers that alternating along the  $a$  axis. The  $[\text{Si}_6\text{O}_{13}]^{2-}$  double layer is built by corner-sharing silicate tetrahedra, forming four-, five-, and eight-membered rings.

(d) Ok, K.-M.; Halasyamani, P. S. *J. Solid State Chem.* **2006**, *179*, 1345. (e) Ok, K.-M.; Orzechowski, J.; Halasyamani, P. S. *Inorg. Chem.* **2004**, *43*, 964. (f) Guesdon, A.; Raveau, B. *Chem. Mater.* **2000**, *12*, 2239.

(26) Kong, F.; Jiang, H.-L.; Mao, J.-G. *J. Solid State Chem.* **2008**, *181*, 263.

The  $\text{TeO}_3^{2-}$  anions in both compounds are only involved in the coordination with the  $\text{La}^{3+}$  ions to form a lanthanum(III) tellurite layer.<sup>26</sup>

We also developed a new SHG material,  $\text{Se}_2\text{B}_2\text{O}_7$ , by the combination of  $\text{BO}_4$  tetrahedra with  $\text{SeO}_3^{2-}$  groups.<sup>27</sup> The structure of  $\text{Se}_2\text{B}_2\text{O}_7$  features a 3D network composed of dimers of corner-sharing  $\text{BO}_4$  tetrahedra and  $\text{SeO}_3$  groups (Figure 14). The open framework of  $\text{Se}_2\text{B}_2\text{O}_7$  can also be described as an interesting mixed (3,4)-connected net of the B and Se atoms (linked by  $-\text{O}-$  bridges). Right-handed helical tunnels along the  $c$  axis are formed. These tunnels are based on  $\text{B}_6\text{Se}_4$  10-membered rings. The lone pairs of the  $\text{Se}^{\text{IV}}$  cations are oriented toward the above tunnels.  $\text{Se}_2\text{B}_2\text{O}_7$  is stable up to 300 °C. It exhibits a SHG efficiency of about 2.2 times that of KDP ( $\text{KH}_2\text{PO}_4$ ).  $\text{Se}_2\text{B}_2\text{O}_7$  is transparent in the range of 300–2000 nm, and it exhibits an optical band gap of 4.64 eV.<sup>27</sup>

## Conclusions and Outlook

Several factors have strong effects on the structural topologies of the resulting compounds. The slight change of the ionic radius of the cation such as the  $A^{\text{I}}$  or  $\text{Ln}^{\text{III}}$  ion could lead to a completely different structure such as, for example,  $\text{A}_2\text{W}_3\text{TeO}_{12}$  ( $A = \text{K}^+, \text{Rb}^+, \text{Cs}^+$ )<sup>12c</sup> and  $\text{Ln}_2\text{MoTe}_3\text{O}_{12}$  ( $\text{Ln} = \text{La}, \text{Nd}$ ).<sup>19a</sup> Also metal tellurites usually show structures different from the corresponding selenites because of the larger ionic radius of  $\text{Te}^{\text{IV}}$  than  $\text{Se}^{\text{IV}}$ , such as, for example,  $\text{Ni}_3(\text{Mo}_2\text{O}_8)(\text{QO}_3)$  ( $Q = \text{Se}, \text{Te}$ ).<sup>21</sup> In some cases, isomerism exists for some metal tellurites. Recently, we obtained a cubic phase of  $\text{Ga}_2\text{Te}_3\text{O}_9$  ( $I\bar{4}3d$ ) and a hexagonal phase of  $\text{Ga}_2\text{Te}_3\text{O}_9$  ( $P6_3/m$ ) in the same hydrothermal reaction; the cubic phase is SHG active ( $1 \times \text{KDP}$ ) and is densely packed, whereas the centrosymmetric hexagonal phase has a much lower density and features a 3D network with large tunnels along the  $c$  axis.<sup>28</sup> Molar ratios of the starting materials, synthetic methods, and reaction temperatures are also very important factors.

Several trends are obvious. The combination of the two types of cations susceptible to SOJT distortion,  $d^0$  TM and lone-pair cation ( $\text{Te}^{\text{IV}}$  or  $\text{Se}^{\text{IV}}$ ), not only gives rise to a rich structural chemistry but also affords many NCS compounds with good SHG properties. As for the direction of the out-of-center distortion, it was found that  $\text{V}^{5+}$  and  $\text{Nb}^{5+}$  usually displace toward an edge or corner, whereas  $\text{Mo}^{6+}$  and  $\text{W}^{6+}$  ions are more likely distorted toward an edge or face. The  $\text{V}^{5+}$  cation may adopt the square-pyramidal geometry besides a tetrahedron and an octahedron. Also it is not as stable as other  $d^0$  TM cations, and sometimes it is reduced to  $\text{V}^{4+}$  during the reaction. The bond polarization follows the following order:  $\text{Te}^{\text{IV}} > \text{Se}^{\text{IV}}$  and  $\text{Mo}^{6+} > \text{V}^{5+} > \text{W}^{6+} > \text{Nb}^{5+} > \text{Ta}^{5+}$ .<sup>2</sup> It is observed that  $\text{Ln}^{\text{III}}$  compounds are seldom acentric and the  $d^0$  TM cations are more likely tetrahedrally coordinated; this may be due to the higher coordination number for the  $\text{Ln}^{\text{III}}$  ions than the  $A^{\text{I}}$  and  $\text{AE}^{\text{II}}$  cations. It is

(28) Kong, F.; Mao, J. G. Unpublished results.

worth mentioning that the  $\text{Se}^{\text{IV}}$  cation exists mostly as a  $\text{SeO}_3$  group (in some cases as the diselenite group), whereas  $\text{Te}^{\text{IV}}$  can be three-, four-, or five-coordinated, and the most amazing aspect is that these  $\text{TeO}_x$  ( $x = 3-5$ ) polyhedra can be polymerized into many types of polynuclear clusters or extended skeletons (Scheme 1) besides a ditellurite anion; such a polymerization is hardly observed in the organically templated or organically covalently bonded metal tellurites. Inorganic solids with various polymeric tellurium(IV) oxide anions include a  $\text{Te}_3\text{O}_8^{4-}$  trimer in  $\text{La}_2\text{MoTe}_3\text{O}_{12}$ , a  $\text{Te}_4\text{O}_{11}^{6-}$  tetramer in  $\text{Er}_2\text{Te}_4\text{O}_{11}$ ,<sup>29</sup> a  $\text{Te}_5\text{O}_{13}^{6-}$  pentamer in  $\text{Ln}_5\text{MTe}_7\text{O}_{23}\text{Cl}_3$  ( $\text{Ln} = \text{Pr}, \text{Nd}$ ;  $\text{M} = \text{Mo}, \text{W}$ ), a 1D  $\text{Te}_4\text{O}_{10}^{4-}$  in  $\text{Ln}_2\text{MoTe}_4\text{O}_{14}$  ( $\text{Ln} = \text{Pr}, \text{Nd}$ ), a 1D  $\text{Te}_6\text{O}_{13}^{2-}$  in  $\{\text{Cd}_2(\text{Te}_6\text{O}_{13})\}\cdot\{\text{Cd}_2\text{Cl}_6\}$ , a 1D  $\text{Te}_7\text{O}_{17}^{6-}$  in  $\text{Cd}_7\text{Cl}_8(\text{Te}_7\text{O}_{17})$ , layered  $\text{Te}_3\text{O}_7^{2-}$  in  $\text{La}_2\text{WTe}_6\text{O}_{18}$ , a 2D  $\text{Te}_4\text{O}_9^{2-}$  in  $\text{K}_2\text{Te}_4\text{O}_9\cdot 3.2\text{H}_2\text{O}$ ,<sup>30a</sup> and a 2D  $\text{Te}_2\text{O}_5^{2-}$  in  $\text{Ln}(\text{Te}_2\text{O}_5)\text{X}$  ( $\text{Ln} = \text{Nd}$ ,  $\text{X} = \text{Cl}, \text{Br}$ ;  $\text{Ln} = \text{Gd}$ ,  $\text{X} = \text{Cl}$ ).<sup>30b,c</sup> Certainly more examples will be discovered in the future, and extensive theoretical studies are needed to understand its origin.

(30) (a) Ok, K. M.; Halasyamani, P. S. *Chem. Mater.* **2001**, 13, 4278. (b) Nikiforov, G. B.; Kusainova, A. M.; Berdonosov, P. S.; Dolgikh, V. A.; Lightfoot, P. J. *Solid State Chem.* **1999**, 146, 473. (c) Meier, S. F.; Schleid, T. *Z. Anorg. Allg. Chem.* **2003**, 629, 1575.

There are also many fertile lands for our exploration in the field of metal selenites and tellurites. Systematic investigation on the  $\text{Ln}^{\text{III}}-\text{V}^{5+}$  ( $\text{Nb}^{5+}$ ,  $\text{Ta}^{5+}$ ,  $\text{Ti}^{4+}$ )- $\text{Te}^{\text{IV}}$  (or  $\text{Se}^{\text{VI}}$ )-O systems is expected to afford many compounds with new structural types as well as excellent luminescent materials. The mixing of two types of charge-balancing cations such as  $\text{Ln}-\text{AE}$ ,  $\text{AE}-\text{A}$ , and  $\text{Ln}-\text{A}$  could change the overall charges of the anionic networks in addition to breaking the packing limitation for the single-type cation; thus, a variety of new structures can be obtained. The combination of lone-pair  $\text{Te}^{\text{IV}}$  or  $\text{Se}^{\text{IV}}$  with borate is also quite promising in the search for new SHG materials. In order to exhibit good second-order NLO properties, the above two types of bond polarizations should be "adductive", which is still a great challenge for a synthetic chemist. To fully address these problems, strong interactions between synthetic and theoretical chemists are necessary.
