

“Click” Synthesis of Heteroleptic Tris-Cyclometalated Iridium(III) Complexes: Cu(I) Triazolide Intermediates as Transmetalating Reagents

Shuang Liu, Peter Müller, Michael K. Takase, and Timothy M. Swager*

S Supporting Information

ABSTRACT: Efficient synthesis of heteroleptic tris-cyclometalated Ir(III) complexes $mer\text{-Ir}(\text{C}^{\wedge}\text{N})_2(\text{trpy})$ ($\text{trpy} = 2\text{-}(1H\text{-}[1,2,3]\text{triazol-4-yl})\text{pyridine}$) is achieved by using the Cu(I)-triazolide intermediates formed in “click” reactions as transmetalating reagents. Ligand preparation and cyclometalation of Ir(III) is accomplished in one pot. The robust nature of click chemistry provides opportunities to introduce different functional groups to the cyclometalated system, for example, alkyl, perfluoroalkyl, and aryl moieties. All of the meridional isomers show short-lived phosphorescence at room temperature, both in solution and in the solid state. DFT calculations indicate that the phosphorescence of $mer\text{-Ir}(\text{C}^{\wedge}\text{N})_2(\text{trpy})$ is attributed to the ${}^3\text{MLCT}$ and ${}^3\text{LC}$ mixed excited states, also supported by the broad spectral shape and hypsochromic shift upon media rigidification. The luminescence efficiency and excited state lifetimes of the cyclometalated complexes can be tuned by varying the substituents on the triazole ring, while the emission color is mainly determined by the phenylpyridine-based ligands. Moreover, the trpy ligand can acquire the $\text{N}^{\wedge}\text{N}$ chelating mode under selective reaction conditions. $mer\text{-Ir}(\text{C}^{\wedge}\text{N})_2(\text{trpy})$ complexes isomerize into cationic $[\text{Ir}(\text{C}^{\wedge}\text{N})_2(\text{N}^{\wedge}\text{N}\text{-trpy})]^+$ species instead of their fac isomers upon heating or UV radiation. This can be explained by the strong $trans$ influence exerted by the phenyl groups. The weakened Ir–C(trpy) bonds are likely to be activated and protonated, leading to the switch of the trpy ligand to a thermodynamically more stable $\text{N}^{\wedge}\text{N}$ chelating mode.

INTRODUCTION

Phosphorescence-based organic light emitting diodes (OLEDs) have drawn significant attention due to their ability to harvest both singlet and triplet excitons for electroluminescence.¹ Cyclometalated iridium(III) complexes stand out as the most promising high performance emitters due to their strong Ir–C bonds, which ensure good photo and thermal stability and destabilize the thermally accessible, nonemissive metal centered (MC) states.² This family of complexes exhibits favorable photophysical properties, such as high quantum efficiency, short excited state lifetimes, and, most importantly, tunable emission colors. The triplet emission originates from a mixture of metal-to-ligand charge transfer (${}^3\text{MLCT}$) and ligand-centered (${}^3\text{LC}$) excited states. This strong coupling between the d orbitals of iridium and the π orbitals of the ligands allows facile color tuning through the cyclometalating and ancillary ligands.^{3,4} Aside from their appealing applications as OLEDs, cyclometalated compounds can also be used in light-emitting electrochemical cells (LECs)^{5,6} and as chemical sensors^{7–11} and bioimaging labels.^{12–16} Therefore, efficient and versatile synthetic methods that allow access to a library of cyclometalated compounds will greatly facilitate the screening process for various applications.

Bis- and tris-cyclometalated Ir(III) complexes are commonly synthesized from chloro-bridged Ir(III) dimers $[\text{Ir}(\text{C}^{\wedge}\text{N})_2\text{Cl}]_2$, which can be readily prepared from $\text{IrCl}_3 \cdot n\text{H}_2\text{O}$ and cyclometalating ligands. Thompson et al. reported the first selective synthesis of mer and fac isomers by controlling the reaction temperatures,¹⁷ which stimulated studies on differentiating the photophysical properties of the two isomers. More recently,

μ -hydroxy-bridged Ir(III) dimers and solvated monomeric Ir(III) precursors have also been used to achieve fac/mer selectivity under mild reaction conditions.¹⁸

Transmetalation of metal–halide bonds with organometallic reagents has also been studied as an alternative approach. For example, $\text{Hg}(\text{ppy})\text{Cl}$ ($\text{ppy} = 2\text{-phenylpyridine}$) has been used to prepare monocyclometalated Ir(III) compounds.¹⁹ However, this method has not been extensively applied due to reluctance to work with Hg compounds. Recently, organozinc reagents were used to selectively generate meridional tris-cyclometalated Ir(III) complexes.²⁰ The organozinc reagents were prepared *in situ* via metal exchange reactions after the ligands were treated with $n\text{-BuLi}$. In all instances, the ligands were prefunctionalized to facilitate the lithiation. Unfortunately, the need for highly reactive $n\text{-BuLi}$ and additional synthetic procedures limited the scope of this method. Organolithiums have proven to be inferior to organozincs due to the low stability,²⁰ despite their applications in the synthesis of bis-cyclometalated Pd(II)/Pt(II) complexes.^{21–23} Therefore, it is highly desirable to explore new organometallic reagents that show high functional group tolerance and ease of preparation.

One of the most popular protocols of copper-mediated reactions is the Huisgen 1,3-dipolar cycloaddition reaction of organic azides and alkynes. This well-known “click” reaction provides high yields and regioselectivities under mild reaction

conditions and has found numerous applications in organic synthesis, material science, and biological chemistry.²⁴ The catalytic cycle has been widely accepted to proceed via a Cu(I)–acetylide intermediate and a weakly coordinating azide, followed by cyclization and then hydrolysis of the Cu–C bond.^{24–26} Similar mechanistic steps have been convincingly characterized in a series of studies on Au(I) triazolides wherein the stable Au–C bond allows for the isolation of an intermediate similar to the postulated Cu(I) intermediate in “click” chemistry.^{27,28} Moreover, Wu et al. reported that the Cu(I)–triazolide intermediate can be trapped with electrophiles, such as ICl, to give 1,4,5-trisubstituted triazoles.²⁹ These encouraging results indicate that organocopper intermediates can act as potential transmetalating reagents to “click” the *in situ* generated triazole ligands onto metal centers, which is the critical step in the synthesis of cyclometalated iridium compounds.

1,4-Disubstituted 1,2,3-triazole derivatives prepared by “click” chemistry have been recently investigated as ligands for a variety of transition metals. This family of so-called “click ligands” shows versatile coordination modes when combined with other functional groups. For example, they can act as N[^]N and N[^]N[^]N multidentate donors for Ru(III),^{30–32} Pt(II),^{33,34} and Ir(III) (Figure 1A)^{30,35,36} and other transition metals³⁷ as bipyridine and terpyridine equivalents. The resulting coordination complexes have potential applications as light-emitting materials³⁵ and in LECs.³⁸ Gandelman et al. developed a family of 1,2,3-triazole-based pincer ligands that react with Na₂PdCl₄ or

(COD)PtCl₂ (COD = cyclooctadiene) to give cyclometalated Pd(II) and Pt(II) complexes, compound B in Figure 1.^{39–41} Schubert et al. reported a series of bis-cyclometalated Ir(III) complexes using 4-phenyl-1*H*-[1,2,3]triazoles as cyclometalating ligands (Figure 1C).³⁶ It is important to note that all of these 1,2,3-triazole-type ligands were synthesized, isolated, and purified separately before the cyclometalation was performed.

Herein, we present a highly efficient one-pot procedure to synthesize heteroleptic tris-cyclometalated Ir(III) complexes, ligated by derivatives of 2-phenylpyridine (ppy) and 2-(1*H*-[1,2,3]triazol-4-yl)pyridine (trpy) ligands. The Cu(I)–triazolide intermediates formed in the reaction of organoazides and commercially available 2-ethynylpyridine were used to transmetalate trpy as the third cyclometalating ligand on to the Ir(III) center.

RESULTS AND DISCUSSION

Synthesis and Structural Characterization. Scheme 1 represents the general route to prepare tris-cyclometalated Ir(III) complexes using the *in situ* generated Cu(I)–triazolides (**1**) as transmetalating reagents. 2-Ethynylpyridine was treated with stoichiometric Cu(MeCN)₄PF₆ in THF in the presence of NaH and Et₃N, before the addition of 1-azido-hexane. ¹H NMR spectra of the reaction mixture showed that the cyclization was very efficient and usually proceeded to completion within 1 h at room temperature. To the organocopper-compound-containing mixture was added [Ir(ppy)₂Cl]₂ or [Ir(FFppy)₂Cl]₂ (FFppy = 2-(2,4-difluorophenyl)pyridine) at room temperature and then heated to 65 °C for 4 h. Crystalline Ir(ppy)₂(trpy) (**2a**) and Ir(FFppy)₂(trpy) (**2b**) were isolated in moderate to high yields, after purification by column chromatography. In order to maximize the yield of either **2a** or **2b**, it was essential to prevent intermediate **1** from being quenched by other electrophiles before the transmetalation reaction could occur. Therefore, a strong base, such as sodium hydride, was used as an efficient proton scavenger.

The tolerant and robust nature of the click reaction provides an ideal route to introduce different functional groups to the

cyclometalated system. Alkyl, perfluoroalkyl, and aryl azides, readily prepared from the respective halides in one step, were

tested in this case. The 1,3-dipolar cycloaddition and subsequent transmetalation proceeded smoothly to give compounds **3a–5a** in high yields (>80%). We attribute the slightly lower isolated yield of compound **5a** to repeated purification procedures. All of the isolated compounds exhibit good solubility in common organic solvents, such as tetrahydrofuran, dichloromethane, and toluene.

The tris-cyclometalated compounds obtained by this approach are expected to be meridional isomers. The pyridyl nitrogen atoms adopt a *trans* configuration in the dimeric Ir(III) precursors as confirmed by X-ray crystallography.¹⁸ This coordination geometry has been proven to be stable and able to survive relatively harsh reaction conditions. Therefore, we hypothesized that the tris-cyclometalated Ir(III) complexes obtained would be meridional.²⁰ This hypothesis is supported by comparing the NMR spectra of **2a** and **2b** to literature compounds containing [Ir(ppy)₂]/[Ir(FFppy)₂] fragments.¹⁷

Two representative compounds, **2a** and **2b**, were characterized by X-ray crystallography, using single crystals obtained from the slow evaporation of respective dichloromethane/hexane solutions. Both compounds crystallize in the monoclinic space group *P*2₁/*c*, as racemates of the Δ and Λ enantiomers/helimers. Only the thermal ellipsoid plots of the Δ isomers are depicted in Figure 2 for simplicity. Details of the data quality and a summary of the residual values of the refinements are listed in Table 1, and selected bond lengths and angles are listed in Table 2. Full tables of bond lengths, bond angles, and atomic coordinates are provided in the Supporting Information.

Both tris-cyclometalated compounds adopt the meridional configuration, with the phenyl groups of the two ppy ligands mutually *cis* to each other. The *in situ* generated trpy ligand

completes the octahedral coordination sphere through the pyridyl nitrogen and triazolyl carbon at the 5 position. Compounds 2a and 2b are rare examples of crystallographically characterized complexes with the trpy ligands acting as C[^]N chelates, even though other binding modes have been reported before.^{30,38}

The bond lengths and bond angles of 2a are consistent with values reported for other meridional Ir(III) complexes in the literature. As the X-ray structure of *mer*-Ir(ppy)₃ is not available in the Cambridge Structural Database (CSD), the averaged bond lengths of the Δ and Λ isomers of *mer*-Ir(ppy)₂(trpy) (trpy = 2-(*p*-tolyl)pyridine)⁴² are used as references. The length of the Ir–C(ppy) bond *trans* to Ir–N(trpy) in 2a is 2.016(3) Å, which is comparable to its equivalent in *mer*-Ir(ppy)₂(trpy) (2.010 Å). However, the Ir–C(ppy) bond *trans* to Ir–C(trpy) (2.053(4) Å) is shorter than that of the Ir–C(ppy) *trans* to Ir–C(trpy) (2.074 Å). Meanwhile, the Ir–C(trpy) bond (2.088(4) Å) is longer than the Ir–C(ppy) bond (2.074 Å). Such variation in bond lengths suggests that the Ir–C(ppy) and Ir–C(ppy) bonds have a stronger *trans* influence relative to Ir–C(trpy). In other words, trpy appears to be a weaker cyclometalating ligand than the ppy derivatives based on the bond length analysis. This is probably due to the strongly σ electron-withdrawing nature of the triazolyl group.

The structure of 2b resembles that of 2a, except that the asymmetric unit of 2b consists of two crystallographically independent molecules with little variation in individual bond lengths and bond angles (Table 2). The average bond lengths of the mutually *trans* Ir–C(FFppy) (2.051 Å) and Ir–C(trpy) (2.086 Å) bonds are the same as those observed in 2a, indicating little perturbation upon fluorination of the ppy ligand. The two Ir–N(FFppy) bonds *trans* to each other have slightly longer bond lengths than those of *mer*-Ir(FFppy)₃.⁴³ The Ir–N(trpy) bond is elongated by roughly 0.13 Å in comparison with the *trans* Ir–N(FFppy) bonds.

It is worth noting that a minor Ir(III)-containing product, 6a, was also isolated from the reaction mixture of 2a. High resolution mass spectra (HRMS) of the minor product revealed a parent ion of $m/z = 731.2446$ m/e , which is the same as that of 2a ($m/z = 731.2498$ m/e). The ¹H NMR spectrum of 6a appeared to be similar to that of 2a, with one additional peak as a sharp singlet at 8.75 ppm. Careful examination of the gCOSY NMR spectrum revealed that the ppy ligands and the pyridyl group of the trpy were intact and the extra proton giving rise to the new singlet was completely isolated. The addition of base to a solution of 6a had no effect on its ¹H NMR spectrum, excluding the possibility of 6a

Figure 3. Ortep diagram of 6b (a) and 7b (b). Thermal ellipsoids are drawn at the 50% probability level. Hydrogen atoms and counterions are omitted for clarity.

being a protonated version of 2a. The ¹⁹F NMR spectrum had a doublet signal at –72.99 ppm ($J = 711.0$ Hz), suggesting the presence of fluorophosphate anions (PF₆[–]). On the basis of these characterizations, this minor product was tentatively assigned as a cationic [Ir(ppy)₂(N[^]N[^]trpy)]⁺ complex similar to those reported in the literature.^{30,38} The counterion PF₆[–] was obtained from the reagent Cu(MeCN)₄PF₆. The formation of a similar minor product 6b (22%) was also observed during the synthesis of 2b. The ¹H NMR spectrum of 6b also showed a sharp singlet at 8.78 ppm, in addition to the characteristic ¹⁹F NMR signal for PF₆[–]. Extensive heating or prolonged

reaction time were found to increase the yields of **6a** and **6b**. However, no isolable amount of side products was obtained in other cases.

The single crystal structure of **6b** confirmed the formation of positively charged $[\text{Ir}(\text{FFppy})_2(\text{N}^{\wedge}\text{N_trpy})]^+$. As shown in Figure 3a, the two Ir–N(FFppy) bonds remain *trans* to each other. The pseudo-octahedral geometry of the $[\text{Ir}(\text{FFppy})_2]$ fragment is completed by the pyridyl group and N at the 3 position of the triazole. The Ir–C(trpy) bond in **2b** is cleaved, and the triazolyl group flips to offer a $\text{N}^{\wedge}\text{N}$ binding mode. The hydrogen atom of the newly formed triazolyl C–H bond is located on the residual electron density map and gives rise to the sharp singlet ¹H NMR signal. One hexafluorophosphate anion is also found in the asymmetric unit, in agreement with the ¹⁹F NMR spectrum. The two Ir–N(FFppy) bonds *trans* to each other (2.048(2) and 2.047(3) Å) are the same as those previously reported for $[\text{Ir}(\text{FFppy})_2(\text{N}^{\wedge}\text{N_trpy})]\text{BF}_4$ (2.056 and 2.048 Å), where $\text{N}^{\wedge}\text{N_trpy}$ refers to pyridine-*N*-biphenyl-1,2,3-triazole.³⁸ The two trpy-based Ir–N bonds are elongated due to the strong *trans* influence of the Ir–C(FFppy) bonds. It is interesting to note that the Ir–N(triazolyl_trpy) bond (2.118(2) Å) is shorter than the N(pyridyl_trpy) bond (2.151(2) Å).

Isomerization. In an attempt to obtain *fac*-Ir($\text{C}^{\wedge}\text{N}$)₂(trpy), **2a** and **2b** were heated in glycerol at 200 °C for 20 h before being treated with a saturated NaCl solution (Scheme 2). Unlike previous cases reported in the literature, ligand scrambling products were not observed, on the basis of ¹H NMR and HRMS characterization of the crude reaction mixture. Nevertheless, ¹H NMR spectra indicated that compounds **7a** and **7b** had similar structures to **6a** and **6b**. The characteristic singlet peak from the triazolyl C–H bond was shifted downfield to 9.07 ppm and 10.95 ppm for **7a** and **7b**, respectively. Additionally, a PF_6^- signal was not observed in the ¹⁹F NMR spectrum.

Single crystals of compound **7b** were obtained by the slow diffusion of hexane into a dichloromethane solution. It is worth noting that **7b** crystallizes in the *P*2₁ space group (*Z* = 2) with only the Δ helimer (Figure 3b). Such enrichment of one optical isomer from a racemic mixture is very rare for transition metal complexes with bidentate ligands. Limited literature reports on the separation of Δ and Λ isomers of cyclometalated compounds indicate the need for either rigid chiral ligands⁴⁴ or chiral chromatography techniques.⁴⁵ The coordination around the Ir(III) center in **7b** greatly resembles that of **6b**, with the trpy ligand acting as a neutral $\text{N}^{\wedge}\text{N}$ chelate. However, the counteranion is a chloride ion in this case, which likely arises from the saturated brine solution used during the workup procedure. Indeed, **6b** and **7b** are interchangeable through simple ion exchange reactions. Treatment with one equivalent of AgPF_6

Figure 4. Photoisomerization of **2a** in DMSO-*d*₆, monitored by ¹H NMR.

in dichloromethane affords **6b** from **7b**, quantitatively. Conversely, **6b** can be converted back to **7b** using excess NaCl.

Such switching of the binding mode of trpy ligands, from $\text{C}^{\wedge}\text{N}$ to $\text{N}^{\wedge}\text{N}$, could also be achieved photochemically. Broadband UV radiation of DMSO-*d*₆ solutions of **2a** and **2b** afforded the respective cationic Ir(III) species. The conversion was monitored by ¹H NMR spectroscopy, and only a single product was observed (Figure 4). After the isomerization was completed, the reaction mixtures were treated with excess saturated NaCl solution. The isolated products showed identical NMR and HRMS spectra to those of **7a** and **7b**, respectively. Evidence of the formation of *fac*-Ir($\text{C}^{\wedge}\text{N}$)₂(trpy) under either the thermal or the photochemical conditions was not obtained. Moreover, treatment of **2a** with acetic acid and silica gel in dichloromethane also failed to produce the *fac* isomer.⁴⁶

The mechanism of the *mer*-to-*fac* isomerization of tris-cyclometalated Ir(III) compounds is believed to involve the dissociation of one of the mutually *transoid* nitrogen atoms and protonation of at least one of the Ir–C bonds, as indicated by the unavoidable ligand scrambling.^{17,42} The proton source is either the alcoholic solvent or the activated C–H bond of an incoming ligand. The energy needed for the C–H activation is compensated by the rearrangement of the coordination geometry and the chelation effect. However, the trpy ligand used in this study can offer both $\text{C}^{\wedge}\text{N}$ and $\text{N}^{\wedge}\text{N}$ coordination modes, the latter being an analogue of the commonly used bipyridine ligand. As discussed in the previous section, the Ir–C(trpy) bond is considerably longer than the Ir–C(pppy) bonds in **2a** and **2b**. Therefore, it is most likely to be activated prior to either the Ir–C(pppy) or Ir–C(FFppy) fragments upon heating or UV radiation. Once the triazole C-5 is protonated, the $\text{N}^{\wedge}\text{N}$ chelating mode of the trpy offers a thermodynamically stable product, which prevents isomerization of the ppy ligands. It should be pointed out that the proton source is the glycerol solvent during

Scheme 3. Failed Attempts to Synthesize Tris-Cyclometalated Iridium(III) Complexes by Literature Methods^a

^a (a) (1) AgPF₆, MeCN; (2) *o*-dichlorobenzene, 100 °C, 48 h; (b) AgPF₆, 2-ethoxyethanol, 140 °C, 24 h.

the thermal isomerization, as previously reported for the *mer*-to-*fac* isomerization.^{17,42} The counterion during the thermal isomerization is likely to be glycerolate ions before the addition of NaCl. In the case of photochemical isomerization, the integration of the singlet corresponding to the triazolyl C–H increased proportionally with other aromatic protons from the ppy and trpy ligands, which precluded the formation of the C–D bond (Figure S5, Supporting Information). A slight increase of the pH values of the reaction mixture was also observed, in agreement with the formation of hydroxide counterions. Therefore, it is likely that the residual water acted as the proton source instead of DMSO-*d*₆.

This speculation is further supported by control reactions attempted in order to prepare heteroleptic cyclometalated Ir(III) compounds following the established procedures (Scheme 3).^{18,47} However, only the N[^]N chelating complexes could be isolated, even in refluxing ethoxyethanol. Therefore, the transmetalation approach described in this work is most likely the only way to use the trpy ligand as a C[^]N chelator.

Electronic Spectroscopy. The absorption spectra of all of the meridional tris-cyclometalated Ir(III) complexes are given in Figure 5a. Compounds 2a–5a show intense absorption between 235 and 350 nm, which can be assigned to ligand-centered transitions.³ These spin-allowed π – π^* bands are accompanied by weaker spin-allowed and spin-forbidden charge transfer transitions in the visible region up to 480 nm. The band shapes and extinction coefficients are comparable to other ppy-based cyclometalated complexes, such as *mer*-Ir(ppy)₃.¹⁷

All of the ppy-based meridional isomers show green phosphorescence at room temperature. Normalized photoluminescence (PL) spectra recorded in deoxygenated THF solutions and poly(methyl methacrylate) (PMMA) thin films are provided in Figure 5. Broad and structureless PL emission bands are observed across the series of *mer*-Ir(ppy)₂(trpy) in solution. In contrast, blue-shifted and relatively structured emission spectra and higher quantum yields are observed in the solid state. These observations suggest that the phosphorescence is based on excited states with strong ³MLCT character. The low quantum efficiency and short triplet state lifetime in solutions likely arise from the distortion or even cleavage of Ir–N and Ir–C bonds upon excitation, which may be responsible for the photoisomerization processes described in the previous section.

The absorption spectrum of FFppy-based 2b exhibits similar spectral features to 2a, except for a hypsochromic shift, consistent with the absorption spectra of the free ppy and FFppy ligands. Unlike its ppy-based analogues, 2b exhibits a more structured and narrower PL spectrum in solution, with an emission maximum at 464 nm. Similar trends have also been observed with

other Ir and Pt compounds bearing FFppy ligands.^{17,48} It has been recognized that the difluoro substitution stabilizes the HOMO more than the LUMO level, resulting in an increase in the band gap.^{4,49}

Although there is little change in terms of the band shape or emission color of compounds with different substituents on the trpy ligands (2a–5a), greater differences are observed in the luminescence efficiency. The perfluorooctyl pedant chain rigidifies the molecule and provides efficient insulation between individual molecules.⁵⁰ As a result, aggregation induced quenching processes are minimized. Consistent with these arguments, 3a exhibits the highest quantum yield (17%) in the solid state across the series. On the other hand, the pentafluorophenyl group introduces strong intermolecular interactions. Accordingly, aggregation induced bathochromic shift in the PL spectrum of 5a is observed even when the concentration is as low as 4×10^{-6} M. Moreover, crystals of 5a exhibit yellow phosphorescence under UV radiation instead of the green emission observed for all the other *mer*-Ir(ppy)₂(trpy) complexes. Differences are also evident in terms of lifetimes. Compounds 2a and 4a show comparable lifetimes to those of previously reported meridional tris-cyclometalated Ir(III) complexes, such as *mer*-Ir(ppy)₃ (0.15 μ s),¹⁷ while highly fluorinated 3a and 5a both show longer lifetimes. Hence, it can be established that certain photophysical properties can be tuned by varying the substituents on the triazole ring (see Table 3 for selected photophysical data of complexes 2–5). Many potential applications can be envisioned considering the huge library of organo azides established in the literature.

The positively charged [Ir(C[^]N)₂(N[^]N_trpy)]⁺ complexes exhibit photophysical properties distinct from those of their tris-cyclometalated counterparts (Figure 6). The absorption spectra show well-defined absorption bands at around 385 nm for 6a/7a and 363 nm for 6b/7b. The room temperature solution PL spectra show well resolved vibronic structures typical of this type of complex.^{30,38} These highly structured emission spectra indicate that the excited state is primarily ligand based. The emission maximum is also slightly blue-shifted relative to the corresponding meridional compounds. For complexes with PF₆[–] and Cl[–] anions, the excited state lifetimes and PL quantum efficiencies show counterion dependency, despite their nearly identical absorption and PL spectra. The excited states of the chlorides 7a and 7b display longer lifetimes and higher quantum yields than 6a and 6b, respectively. This difference has been observed previously between [Ir(FFppy)₂(N[^]N_trpy)]PF₆ and [Ir(FFppy)₂(N[^]N_trpy)]BF₄, and it is attributed to varying packing interactions when the cations are not fully solvated.³⁸ Indeed, an examination of the packing diagrams of 6b and 7b

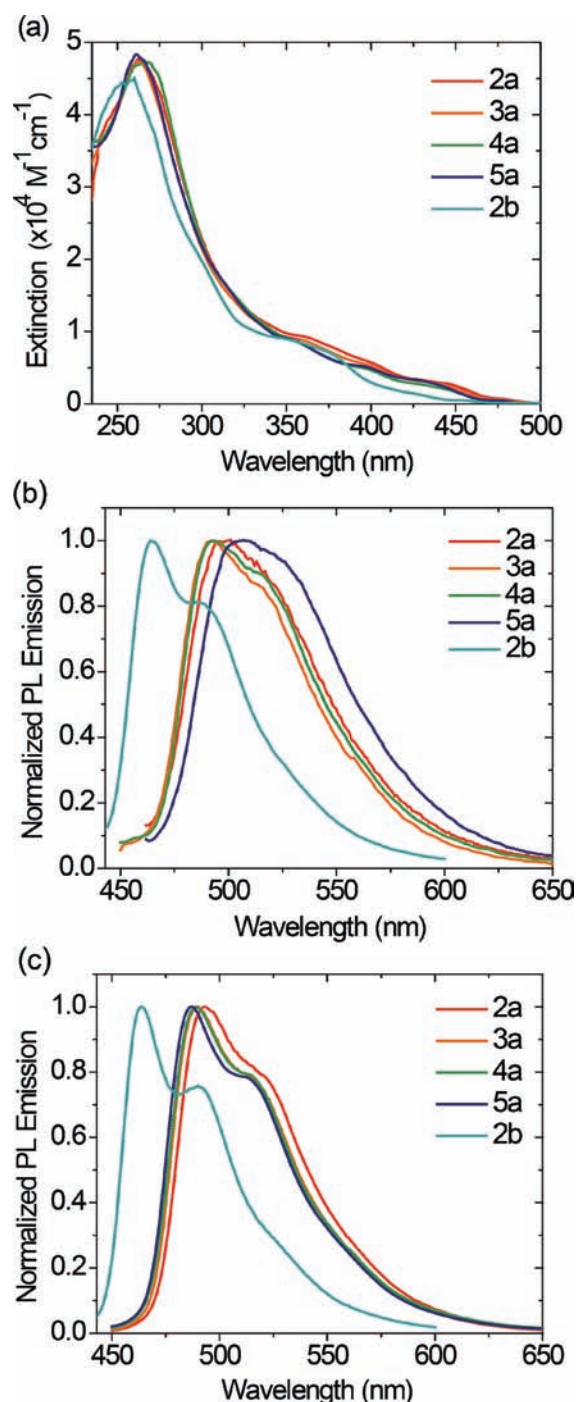

Figure 5. UV-vis absorption (a) and emission (b) spectra of all the *mer*-Ir(C^{^N})₂(trpy) compounds in THF (10⁻⁶ M, under Ar), as well as the photoluminescence spectra in PMMA thin films (c).

reveals that PF₆⁻ and Cl⁻ ions show different H-bonding interactions with the FFppy and trpy ligands in the solid state (Figures S1 and S2, Supporting Information).

In order to gain insights into the different electronic structures and photophysical properties of the neutral and cationic Ir(III) complexes, density functional theory (DFT) calculations were performed on two simplified structures *mer*-Ir(ppy)₂(trpy) and [Ir(ppy)₂(N^{^N}_trpy)]⁺. The optimized ground-state geometries closely resemble the solid state structures determined by

X-ray diffraction. The most important frontier orbitals of the two model compounds are shown in Figure 7. The highest occupied molecular orbitals (HOMOs) of the two model compounds are both composed of a mixture of the d orbitals of iridium and the π orbitals of the two ppy-based phenyl groups, typical for bis- or tris-cyclometalated Ir(III).^{3,4} However, the lowest unoccupied molecular orbitals (LUMOs) appear to be remarkably different. As for *mer*-Ir(ppy)₂(trpy), the LUMO is localized primarily on the ppy ligand that has a transoid Ir–C bond with the trpy. Such atomic orbital composition of the frontier molecular orbitals is very typical for meridional bis-cyclometalated Ir(III) complexes.¹⁷ The absence of a significant contribution from the substituted triazolyl group to the frontier orbitals explains the almost identical absorption and emission spectra observed for 2a–5a. The LUMO for [Ir(ppy)₂(N^{^N}_trpy)]⁺, on the other hand, is dominated by the π* orbital of the N^{^N}_trpy ligand with little overlap with the HOMO. The orbital diagram of the Ir(III) cation greatly resembles that of bis-cyclometalated complexes with neutral diimine ligands, such as 2,2'-bipyridine (bpy) and 1,10-phenanthroline. The HOMO of [Ir(ppy)₂(bpy)]⁺ is also a mixture of iridium d and phenyl π orbitals, while the LUMO is primarily on the bpy ligand.^{51,52} Studies on the excited states have confirmed the mixed ³MLCT and ligand-to-ligand charge transfer (³LLCT) character of the low-lying triplet states. Therefore, the low energy absorption of *mer*-Ir(ppy)₂(trpy) can be attributed to excitation to mixed ³MLCT and ³LC excited states of ppy, while the low-lying excited states of [Ir(ppy)₂(N^{^N}_trpy)]⁺ have an important ³LLCT character between the ppy and trpy ligands. This is in good agreement with the highly structured emission spectra and longer phosphorescence lifetimes observed for 6 and 7 relative to their C^{^N}_trpy counterparts. Since the neutral N^{^N}_trpy ligands are better π acceptors than the anionic C^{^N}_trpy, stronger back bonding from the metal center to N^{^N}_trpy would further stabilize the Ir d orbitals while destabilizing the ligand π* orbitals. This stabilization of the HOMO and destabilization of the LUMO led to the hypsochromic shift observed upon switching from the C^{^N} chelating mode to N^{^N}.

CONCLUSION

In summary, we demonstrated that Cu(I)-triazolides generated by click chemistry can be used to facilitate the synthesis of tris-cyclometalated Ir(III) complexes. This route represents an efficient one-pot procedure for both ligand preparation and cyclometalation. *mer*-Ir(C^{^N})₂(trpy) with various substituents of the triazole groups are isolated in moderate to high yields and fully characterized. These meridional Ir(III) compounds show short-lived phosphorescence at room temperature, and their quantum efficiencies can be perturbed by varying the cyclometalating ligands. The robust nature of the click chemistry affords the possibility of introducing different lateral functional groups to the ligand that can act as sensing receptors or anchor groups. Many potential applications can be envisioned considering the diversity of organoazides established in the literature. The isomerization of neutral *mer*-Ir(C^{^N})₂(trpy) to positively charged [Ir(C^{^N})₂(N^{^N}_trpy)]⁺ is also discussed in detail. The neutral N^{^N} chelating mode is thermodynamically favored compared to the anionic C^{^N} mode. Therefore, the transmetalation approach described in this work is required to utilize trpy as a cyclometalating ligand.

^aMeasured in deoxygenated THF solution ($\sim 10^{-5} \text{ M}$) at room temperature. ^bDetermined by comparison with Coumarin-343 (ethanol, $\Phi = 0.63$).⁵³ ^cMeasured in PMMA films doped with 2–5 wt % of the Ir(III) compounds. ^dDetermined by comparison with perylene (PMMA film, QY = 0.98)⁵⁴ and 9,10-diphenylanthracene (PMMA film, QY = 0.83).⁵⁵ ^eMeasured in THF with 5% v/v of CH_2Cl_2 due to the low solubility of 7a in THF.

Figure 6. UV–vis absorption (a) and emission (b) spectra of the $[\text{Ir}(\text{C}^{\wedge}\text{N})_2(\text{N}^{\wedge}\text{N}_2\text{trpy})]^+$ compounds in THF (10^{-6} M , under Ar).

EXPERIMENTAL SECTION

General Methods and Instrumentation. All reactions were performed under an argon atmosphere, using oven-dried glassware and standard Schlenk techniques. ^1H and $^{13}\text{C}\{^1\text{H}\}$ NMR spectra were recorded on either a Bruker 400 MHz or Varian 500 MHz spectrometer

Figure 7. Contour plots of frontier orbitals of *mer*-Ir(ppy)₂(trpy) (a) and $[\text{Ir}(\text{ppy})_2(\text{N}^{\wedge}\text{N}_2\text{trpy})]^+$ (b).

and referenced to the residual proton or carbon resonance of the deuterated solvent. ^{19}F NMR spectra were recorded on a Varian 300 MHz spectrometer and referenced to an external standard CFCl_3 (0 ppm). Electrospray ionization (ESI) high resolution mass spectrometry (HRMS) was measured on a Bruker Daltonics APEXIV 4.7 T Fourier Transform Ion Cyclotron Resonance Mass Spectrometer, and the most abundant masses are reported.

UV/vis spectra were recorded on an Agilent 8453 diode-array spectrophotometer. Emission spectra were acquired on a SPEX Fluorolog fluorometer (model FL-321, 450 W xenon lamp) using either right-angle detection (solution measurements) or front-face detection (thin film measurements). All room temperature solution samples for emission spectra were degassed by at least three freeze–pump–thaw cycles in an anaerobic cuvette. Solution photoluminescence quantum yields were

determined against Coumarin-343 (ethanol, QY = 0.63)⁵³ and corrected for solvent refractive index and absorption differences at the excitation wavelength. Thin films were prepared by spin-coating a chloroform solution of poly(methyl methacrylate) (PMMA) and the target compound (5–10% w/w relative to PMMA). Perylene (PMMA film, QY = 0.98)⁵⁴ or 9,10-diphenylanthracene (PMMA film, QY = 0.83)⁵⁵ were used as the reference materials. Phosphorescence lifetimes were determined by time-resolved phosphorescence spectroscopy. The radiation source was an Oriol nitrogen laser (Model 79111) with a 5 ns pulse width operating at approximately 25 Hz. The emitted light was dispersed in an Oriol MS-260i spectrograph with a 600 lines/mm grating. The detector was an Andor Technologies Intensified CCD camera (1024 × 128 pixels) with an onboard delay generator and a minimum gate width of 5 ns operating in full vertical binning mode and triggered by a TTL prepulse from the nitrogen laser. The detector was calibrated with a Hg(Ar) pencil-style calibration lamp. Solution data were acquired with a horizontal binning of 2 or 3. Fifteen spectra at different delay times after the laser pulse were taken per lifetime measurement, the integrated intensities of which were fit to a single-exponential function.

Materials and Synthesis. Iridium(III) chloride hydrate (IrCl₃·nH₂O) and tetrakis(acetonitrile)copper(I) hexafluorophosphate (Cu(MeCN)₄PF₆) were purchased from Strem Chemicals. 2-Ethynylpyridine, 2-(2,4-difluorophenyl)pyridine, NaH (60% dispersion in mineral oil), and all other reagents were obtained from Aldrich Chemicals and used as received. Anhydrous tetrahydrofuran was obtained from a solvent purification system (Innovative Technologies). Triethylamine (Et₃N) was distilled over sodium hydroxide pellets and stored under argon. *μ*-Chloro-bridged Ir(III) dimers,¹⁷ 1-azidohexane,⁵⁶ 1-azido-2-(perfluorooctyl)ethane,⁵⁷ 1-azido-3-(trifluoromethyl)benzene,⁵⁶ and 1-azidopentafluorobenzene⁵⁸ were prepared according to the literature methods.

Caution! There have been safety concerns about handling organoazides, especially the ones with short alkyl groups. Therefore, all the organoazides used in this report were synthesized on small scales and handled with great care.

Preparation of mer-Ir(ppy)₂(trpy-C₆H₁₃) (2a). 2-Ethynylpyridine (41 mg, 0.4 mmol) in THF (8 mL)/Et₃N (0.1 mL) was added to a mixture of Cu(MeCN)₄PF₆ (149 mg, 0.4 mmol) and NaH (19 mg, 0.8 mmol), and the resulting suspension was stirred for 0.5 h at room temperature before 1-azidohexane (51 mg, 0.4 mmol) in THF (2 mL) was added. After stirring at room temperature for another 1–1.5 h, [Ir(ppy)₂Cl]₂ (107 mg, 0.1 mmol) was added to the mixture as a solid and heated to 65 °C for 4 h. After cooling, the solvent was removed under reduced pressure, and the residue was purified by chromatography on silica gel, using CH₂Cl₂/ethyl acetate (15:1) as the eluent to remove a small amount of side product 6a and then CH₂Cl₂/ethyl acetate (6:1) to collect the desired product 2a. After recrystallization from CH₂Cl₂/hexane, 2a was isolated as bright yellow crystals (127 mg, 87%). HRMS (ESI): 731.2498 [calcd for (M + H)⁺: 731.2415]. ¹H NMR (400 MHz, DMSO-*d*₆, ppm): 0.76 (t, J = 7.2 Hz, 3 H), 0.87–1.00 (m, 4 H), 1.06 (m, 2 H), 1.21 (m, 2 H), 3.4 (m, 2H), 6.27 (d, J = 7.2 Hz, 1 H), 6.31 (d, J = 7.6 Hz, 1 H), 6.72 (t, J = 7.4 Hz, 1 H), 6.83 (t, J = 7.4 Hz, 1 H), 6.88 (t, J = 7.4 Hz, 1 H), 6.95 (t, J = 7.6 Hz, 1 H), 6.99 (t, J = 6.3 Hz, 1 H), 7.07 (m, 2 H), 7.52 (d, J = 5.4 Hz, 1 H), 7.56 (d, J = 5.7 Hz, 1 H), 7.75–7.84 (m, 5 H), 7.87 (d, J = 5.7 Hz, 1 H), 7.91 (d, J = 7.9 Hz, 1 H), 8.12 (d, J = 7.9 Hz, 1 H), 8.13 (d, J = 7.9 Hz, 1 H). ¹³C NMR (126 MHz, CD₂Cl₂, ppm): 14.4, 23.1, 26.7, 32.7, 51.1, 118.1, 119.0, 119.5, 120.4, 121.5, 122.1, 122.5, 123.2, 124.6, 124.9, 130.0, 130.6, 131.6, 132.3, 136.0, 137.0, 138.2, 143.5, 145.5, 149.4, 151.1, 152.5, 154.1, 158.8, 162.8, 168.1, 169.4, 170.1.

Compound 6a was isolated as a bright yellow solid (20 mg, 11%). HRMS (ESI): 731.2446 [calcd for (M-PF₆)⁺: 731.2415]. ¹H NMR (400 MHz, DMSO-*d*₆, ppm): 0.84 (t, J = 6.82 Hz, 3 H), 1.12–1.38 (m, 6 H), 1.83–1.98 (m, 2 H), 4.45 (t, J = 7.4 Hz, 2 H), 6.30 (d, J = 5.3 Hz, 1 H), 6.32 (d, J = 5.3 Hz, 1 H), 6.87 (t, J = 7.5 Hz, 1 H), 6.93 (t, J = 7.5 Hz, 1 H), 6.97–7.11 (m, 4 H), 7.30 (t, J = 6.3 Hz, 1 H), 7.51 (d, J = 5.8 Hz, 1 H), 7.66–7.71 (m, 2 H), 7.73 (d, J = 7.3 Hz, 1 H), 7.75–7.82 (m, 2 H), 7.84

(d, J = 5.3 Hz, 1 H), 7.95 (d, 2 H), 8.02 (t, J = 7.6 Hz, 1 H), 8.22 (d, J = 7.8 Hz, 1 H), 8.75 (s, 1 H). ¹³C NMR (126 MHz, CD₂Cl₂, ppm): 14.2, 22.9, 26.3, 30.2, 31.4, 53.1, 120.1, 120.2, 122.7, 123.3, 123.5, 123.6, 123.9, 124.9, 125.3, 126.2, 127.0, 130.4, 131.1, 132.1, 132.4, 138.6, 138.7, 140.2, 144.5, 146.8, 149.0, 149.8, 149.9, 150.0, 150.8, 167.9, 168.5. ¹⁹F NMR (282 MHz, CD₂Cl₂, δ ppm): –72.99 (d, J = 711.0 Hz).

Preparation of mer-Ir(FFppy)₂(trpy-C₆H₁₃) (2b). 2-Ethynylpyridine (21 mg, 0.2 mmol), Cu(MeCN)₄PF₆ (75 mg, 0.2 mmol), NaH (10 mg, 0.4 mmol), and 1-azidohexane (25 mg, 0.2 mmol) were reacted with [Ir(FFppy)₂Cl]₂ (61 mg, 0.05 mmol) following the procedure detailed for the synthesis of 2a. The reaction mixture was purified by chromatography on silica gel, using CH₂Cl₂/ethyl acetate (10:1 to 8:1) as the eluent to remove a small amount of side product 6b and then CH₂Cl₂/ethyl acetate (4:1) to collect the desired product 2b. Compound 2b was isolated as light yellow crystals (91 mg, 57%). HRMS (ESI): 803.2108 [calcd for (M+H)⁺: 803.2101]. ¹H NMR (400 MHz, CD₂Cl₂, δ ppm): 0.82 (t, J = 7.3 Hz, 3 H), 1.04 (quin, J = 7.4 Hz, 2 H), 1.09–1.22 (m, 4 H), 1.33–1.45 (m, 2 H), 3.57–3.74 (m, 2 H), 5.87 (m, 2 H), 6.48 (m, 2 H), 6.83–6.93 (m, 3 H), 7.59–7.65 (m, 2 H), 7.66–7.75 (m, 3 H), 7.97 (d, J = 5.3 Hz, 1 H), 8.02 (br. d, J = 5.3 Hz, 1 H), 8.25 (d, J = 8.3 Hz, 2 H). ¹³C NMR (126 MHz, CD₂Cl₂, δ ppm): 14.3, 23.1, 26.9, 32.0, 32.8, 51.2, 96.7 (t, J = 27.6 Hz), 98.5 (t, J = 27.6 Hz), 113.4 (dd, J = 16.7, 2.9 Hz), 113.8 (dd, J = 15.3, 2.6 Hz), 118.5, 121.9, 122.9, 123.1 (d, J = 19.6 Hz), 123.5, 123.7 (d, J = 19.0 Hz), 127.8, 128.8, 137.1, 138.1, 138.9, 149.5, 150.9, 154.0, 156.7 (d, J = 6.9 Hz), 158.4, 160.91 (d, J = 13.2 Hz), 161.5 (d, J = 11.5 Hz), 162.8 (d, J = 12.1 Hz), 163.0 (d, J = 13.2 Hz), 163.6 (d, J = 11.5 Hz), 163.8 (d, J = 10.9 Hz), 164.7, 164.8, 165.9 (d, J = 10.9 Hz), 166.5 (d, J = 8.1 Hz), 174.3. ¹⁹F NMR (282 MHz, CD₂Cl₂, δ ppm): –111.24 (t, J = 9.2 Hz), –110.16 (t, J = 12.2 Hz), –109.46 (d, J = 9.2 Hz), –108.83 (d, J = 9.2 Hz).

Compound 6b was isolated as light yellow solids (43 mg, 22%). HRMS (ESI): 803.2056 [calcd for (M – PF₆)⁺: 803.2101]. ¹H NMR (400 MHz, CD₂Cl₂, δ ppm): 0.84 (t, J = 6.8, 3 H), 1.15–1.30 (m, 6 H), 1.86–1.97 (m, 2 H), 4.46 (t, J = 7.3 Hz, 2 H), 5.73 (dd, J = 8.6, 2.1 Hz, 1 H), 5.79 (dd, J = 8.4, 2.1 Hz, 1 H), 6.55 (ddd, J = 12.2, 9.5, 2.1 Hz, 1 H), 6.61 (ddd, J = 12.1, 9.5, 2.2 Hz, 1 H), 7.04 (t, J = 6.4 Hz, 1 H), 7.10 (t, J = 6.3 Hz, 1 H), 7.37 (t, J = 6.4 Hz, 1 H), 7.50 (d, J = 5.7 Hz, 1 H), 7.64 (d, J = 5.7 Hz, 1 H), 7.80–7.89 (m, 3 H), 8.08 (td, J = 7.8, 1.0 Hz, 13 H), 8.26 (d, J = 8.1 Hz, 1 H), 8.31 (d, 2 H), 8.78 (s, 1 H). ¹³C NMR (126 MHz, CD₂Cl₂, δ ppm): 14.2, 22.9, 29.3, 30.1, 31.3, 53.3, 99.2 (t, J = 27.1 Hz), 99.7 (t, J = 27.1 Hz), 114.5, 1114.6 (d, J = 12.1 Hz), 114.7 (d, J = 12.1 Hz), 114.8, 123.9, 124.0, 124.2–124.3 (m), 126.7, 127.3, 128.5, 139.6, 139.7, 140.9, 148.8, 149.1, 149.9, 150.0, 150.4 (d, J = 6.9 Hz), 150.7, 153.8 (d, J = 6.3 Hz), 160.5 (d, J = 12.7 Hz), 160.9 (d, J = 12.7 Hz), 162.5 (d, J = 8.6 Hz), 162.6 (d, J = 9.2 Hz), 163.0 (d, J = 12.7 Hz), 163.1 (d, J = 12.7 Hz), 164.5–164.6 (m), 165.1–165.2 (m). ¹⁹F NMR (282 MHz, CD₂Cl₂, δ ppm): –111.09 (1 F), –109.23 (1 F), –107.75 (1 F), –106.85 (1 F), –72.86 (d, J = 717.2 Hz, 6 F).

Preparation of mer-Ir(ppy)₂(trpy-C₂H₄CF₁₇) (3a). 2-Ethynylpyridine (41 mg, 0.4 mmol), Cu(MeCN)₄PF₆ (149 mg, 0.4 mmol), NaH (19 mg, 0.8 mmol), and 1-azido-2-(perfluorooctyl)ethane (196 mg, 0.4 mmol) were reacted with [Ir(ppy)₂Cl]₂ (107 mg, 0.1 mmol) following the procedure detailed for the synthesis of 2a. The reaction mixture was purified by chromatography on silica gel, using CH₂Cl₂/ethyl acetate (8:1) as the eluent. Compound 3a was isolated as bright yellow crystals (133 mg, 61%). HRMS (ESI): 1093.1473 [calcd for (M + H)⁺: 1091.1503]. ¹H NMR (500 MHz, CD₂Cl₂, ppm): 1.85–2.05 (m, 1 H), 2.10–2.27 (m, 1 H), 3.99–4.12 (m, 2 H), 6.44 (d, J = 7.2 Hz, 1 H), 6.46 (d, J = 7.7 Hz, 1 H), 6.78–6.89 (m, 4 H), 6.92 (t, J = 7.6 Hz, 1 H), 6.96 (t, J = 7.4 Hz, 1 H), 7.03 (t, J = 7.2 Hz, 1 H), 7.59–7.76 (m, 7 H), 7.87 (d, 2 H), 7.98 (d, J = 5.4 Hz, 1 H), 8.06 (d, J = 7.7 Hz, 1 H). ¹³C NMR (126 MHz, CD₂Cl₂, ppm): 32.9 (t, J = 21.3 Hz), 42.8 (t, J = 4.0 Hz), 108.9–120.12 (m, CF₂ and CF₃), 118.4, 119.1, 119.7, 120.9, 121.9, 122.4, 122.7, 123.3, 124.9, 125.0, 130.3, 130.8, 131.4, 132.2, 136.2, 137.2,

138.4, 143.3, 145.4, 149.6, 151.2, 151.6, 153.9, 158.5, 163.6, 168.0, 168.7, 170.1. ^{19}F NMR (282 MHz, CD_2Cl_2 , ppm): -126.63 , -124.31 , -123.21 , -122.41 , -122.23 , -115.20 , -81.40 .

Preparation of *mer*-Ir(ppy) $_2$ (trpy-C $_6$ H $_4$ CF $_3$) (4a). 2-Ethynylpyridine (21 mg, 0.2 mmol), $\text{Cu}(\text{MeCN})_4\text{PF}_6$ (75 mg, 0.2 mmol), NaH (10 mg, 0.4 mmol), and 1-azido-3-(trifluoromethyl)benzene (37 mg, 0.2 mmol) were reacted with $[\text{Ir}(\text{ppy})_2\text{Cl}]_2$ (54 mg, 0.05 mmol) following the procedure detailed for the synthesis of **2a**. The reaction mixture was purified by chromatography on silica gel, using CH_2Cl_2 /ethyl acetate (15:1) as the eluent. Compound **4a** was isolated as bright yellow crystals (72 mg, 91%). HRMS (ESI): 791.1709 [calcd for $(\text{M} + \text{H})^+$: 791.1726]. ^1H NMR (400 MHz, CD_2Cl_2 , ppm): 6.08 (d, $J = 7.6$ Hz, 1 H), 6.33 (d, $J = 7.3$ Hz, 1 H), 6.53 (t, $J = 8.1$ Hz, 1 H), 6.75 (t, $J = 7.3$ Hz, 1 H), 6.81–6.89 (m, 4 H), 6.92 (t, $J = 7.3$ Hz, 1 H), 7.00 (t, $J = 7.6$ Hz, 1 H), 7.04 (d, $J = 8.1$ Hz, 1 H), 7.28 (d, $J = 7.8$ Hz, 1 H), 7.48 (d, $J = 7.6$ Hz, 1 H), 7.59–7.69 (m, 6 H), 7.72 (t, $J = 7.8$ Hz, 1 H), 7.81 (d, $J = 8.1$ Hz, 1 H), 7.84 (d, $J = 8.1$ Hz, 1 H), 8.06 (d, $J = 5.6$ Hz, 1 H), 8.13 (d, $J = 7.8$ Hz, 1 H). ^{13}C NMR (126 MHz, CD_2Cl_2 , ppm): 118.7, 119.1, 119.7, 120.5, 120.9, 122.1, 122.4, 122.5, 123.5, 123.8, 124.6, 124.9, 125.9, 127.6, 129.1, 129.8, 130.8, 131.6, 132.0, 136.2, 137.2, 138.4, 141.1, 143.2, 145.3, 149.5, 150.9, 153.0, 154.1, 158.3, 159.1, 163.8, 167.1, 168.0, 169.8. ^{19}F NMR (282 MHz, CD_2Cl_2 , ppm): -62.82 .

Preparation of *mer*-Ir(ppy) $_2$ (trpy-C $_6$ F $_5$) (5a). 2-Ethynylpyridine (41 mg, 0.4 mmol), $\text{Cu}(\text{MeCN})_4\text{PF}_6$ (149 mg, 0.4 mmol), NaH (19 mg, 0.8 mmol), and 1-azidopentafluorobenzene (84 mg, 0.4 mmol) were reacted with $[\text{Ir}(\text{ppy})_2\text{Cl}]_2$ (107 mg, 0.1 mmol) following the procedure detailed for the synthesis of **2a**. The reaction mixture was purified by chromatography on silica gel, using CH_2Cl_2 /ethyl acetate (15:1) as the eluent. Compound **5a** was isolated as bright yellow crystals (77 mg, 48%). Samples for photophysical study were purified by preparative thin layer chromatography (PTLC) to remove trace amounts of contaminants using CH_2Cl_2 /ethyl acetate (30:1) as the eluent. HRMS (ESI): 813.1367 [calcd for $(\text{M} + \text{H})^+$: 813.1381]. ^1H NMR (400 MHz, CD_2Cl_2 , ppm): 6.15 (d, $J = 7.6$ Hz, 1 H), 6.40 (d, $J = 7.1$ Hz, 1 H), 6.54 (t, $J = 7.4$ Hz, 1 H), 6.72 (t, $J = 7.4$ Hz, 1 H), 6.85–6.95 (m, 4 H), 7.00 (t, $J = 7.6$ Hz, 1 H), 7.45 (d, $J = 7.6$ Hz, 1 H), 7.62–7.78 (m, 6 H), 7.81 (d, $J = 8.3$ Hz, 1 H), 7.85 (d, $J = 8.1$ Hz, 1 H), 8.10 (d, 2 H). ^{13}C NMR (126 MHz, CD_2Cl_2 , ppm): 118.8, 118.9, 119.6, 120.2, 122.4, 122.7, 123.4, 123.9, 124.9, 129.3, 130.7, 131.3, 132.3, 136.5, 137.3, 138.6, 143.4, 145.4, 149.5, 151.1, 151.3, 154.1, 157.8, 158.0, 168.0, 168.2, 168.4, 169.8. ^{19}F NMR (282 MHz, CD_2Cl_2 , ppm): -163.24 (d, $J = 24.4$ Hz), -163.27 (d, $J = 24.4$ Hz), -154.92 (t, $J = 21.4$ Hz), $-146.87 \sim -146.80$ (m).

Thermal Isomerization from **2a to **7a**.** Twenty mg of **2a** was suspended in 5 mL glycerol under Ar. The mixture was heated to 200 °C for 20 h. After cooling to room temperature, the slurry was added with saturated NaCl aqueous solution and extracted with CH_2Cl_2 . The crude mixture was subjected to HRMS (ESI), which showed that there is only trace amount of $\text{Ir}(\text{ppy})(\text{trpy})_2$ (<1%). Compound **7a** was purified by flash chromatography on partially deactivated neutral aluminum oxide (5% H_2O), using CH_2Cl_2 /CH $_3$ OH (97:3) as eluent. After recrystallization from CH_2Cl_2 /hexane, **7a** was isolated as light yellow crystals (14 mg, 63%). HRMS (ESI): 731.25 [calcd for $(\text{M} - \text{Cl})^+$: 731.25]. ^1H NMR (400 MHz, $\text{MeOH}-d_4$, δ ppm): 0.85 (t, $J = 6.8$ Hz, 3 H), 1.10–1.30 (m, 6 H), 1.81–1.95 (m, 2 H), 4.47 (t, $J = 7.1$ Hz, 2 H), 6.24 (d, $J = 7.3$ Hz, 1 H), 6.31 (d, $J = 7.3$ Hz, 1 H), 6.78 (t, $J = 7.0$ Hz, 1 H), 6.88 (t, $J = 7.0$ Hz, 1 H), 6.93 (t, $J = 7.2$ Hz, 1 H), 7.02 (d, $J = 7.1$ Hz, 1 H), 7.04 (d, $J = 7.8$ Hz, 1 H), 7.09 (t, $J = 6.7$ Hz, 1 H), 7.40 (t, $J = 6.2$ Hz, 1 H), 7.63 (d, $J = 5.8$ Hz, 1 H), 7.73 (d, $J = 7.8$ Hz, 1 H), 7.76 (d, $J = 5.6$ Hz, 1 H), 7.81 (d, $J = 7.8$ Hz, 1 H), 7.84–7.91 (m, 3 H), 8.04–8.14 (m, 3 H), 8.26 (d, $J = 7.8$ Hz, 1 H), 9.07 (s, 1 H). ^{13}C NMR (126 MHz, CD_2Cl_2 , δ ppm): 14.2, 22.9, 26.4, 30.4, 31.4, 52.8, 120.0, 120.1, 122.6, 123.1, 123.5, 123.8, 124.8, 125.0, 125.2, 126.5, 129.4, 129.5, 130.3, 131.0, 132.1, 132.4, 138.4, 138.5, 140.2, 144.5, 147.3, 149.1, 149.3, 149.9, 150.2, 150.4, 150.8, 168.0, 168.5.

Thermal Isomerization from **2b to **7b**.** Compound **7b** was prepared following the procedure outlined for **7a** and purified by flash column chromatography on partially deactivated neutral aluminum oxide (5% H_2O), using CH_2Cl_2 /CH $_3$ OH (97:3) as the eluent. After recrystallization from CH_2Cl_2 /hexane, **7b** was isolated as light yellow crystals (12 mg, 58%). HRMS (ESI): 803.2095 [calcd for $(\text{M} - \text{Cl})^+$: 803.2101]. ^1H NMR (400 MHz, CD_2Cl_2 , ppm): 0.83 (t, $J = 6.6$ Hz, 3 H), 1.24 (m, 6 H), 1.83–2.03 (m, 2 H), 4.51 (t, $J = 7.3$ Hz, 2 H), 5.73 (dd, $J = 8.6$, 2.3 Hz, 1 H), 5.80 (dd, $J = 8.6$ Hz, 2.3 Hz, 1 H), 6.54 (ddd, $J = 13.1$, 9.4, 2.3 Hz, 1 H), 6.60 (ddd, $J = 12.9$, 9.3, 2.3 Hz, 1 H), 7.01 (t, $J = 6.7$ Hz, 1 H), 7.06 (t, $J = 6.8$ Hz, 1 H), 7.31 (t, $J = 6.6$ Hz, 1 H), 7.49 (d, $J = 5.8$ Hz, 1 H), 7.65 (d, $J = 5.6$ Hz, 1 H), 7.74–7.90 (m, 3 H), 8.10 (t, $J = 7.8$ Hz, 1 H), 8.30 (d, 2 H), 9.26 (d, $J = 7.8$ Hz, 1 H), 10.95 (s, 1 H). ^{13}C NMR (126 MHz, CD_2Cl_2 , ppm): 14.2, 23.0, 26.4, 30.2, 31.4, 53.0, 99.0 (t, $J = 26.5$ Hz), 99.5 (t, $J = 27.1$ Hz), 114.6 (dd, $J = 6.9$, 2.9 Hz), 114.7 (dd, $J = 6.9$, 2.9 Hz), 123.8, 124.0, 124.1, 124.3, 125.7, 126.8, 128.5, 130.1 (d, $J = 23.6$ Hz), 139.5, 139.6, 140.9, 149.2, 150.0, 150.1, 150.6, 150.9 (d, $J = 6.9$ Hz), 154.4 (d, $J = 6.3$ Hz), 160.5 (d, $J = 12.7$ Hz), 160.9 (d, $J = 12.7$ Hz), 162.5 (d, $J = 11.5$ Hz), 162.6 (d, $J = 11.5$ Hz), 163.0 (d, $J = 12.7$ Hz), 163.1 (d, $J = 12.7$ Hz), 164.5–164.6 (m), 165.1–165.2 (m). ^{19}F NMR (282 MHz, CD_2Cl_2 , ppm): -111.16 , -109.37 , -107.92 , -106.01 .

Photochemical Isomerization. A total of 15 mg of **2a** or **2b** was dissolved in DMSO- d_6 in a NMR tube capped with a rubber septum and purged with Ar for 15 min. The sealed tube was irradiated with a portable pen light with broadband UV radiation, and the reaction completed after 3 days based on ^1H NMR. A saturated NaCl aqueous solution was added, and the mixture was extracted with CH_2Cl_2 . Compounds **7a** (12 mg, 58%) and **7b** were isolated as light yellow crystals.

Crystal Structure Determinations. Low-temperature diffraction data (ρ and ω scans) were collected on a Bruker D8 three-circle diffractometer coupled to a Bruker-AXS Smart Apex CCD detector with graphite-monochromated Cu K α radiation ($\lambda = 1.54178$ Å) for the structures of compounds **2a**, **2b**, and **6b** and on a Bruker-AXS X8 Kappa Duo diffractometer coupled to a Smart Apex2 CCD detector with Mo K α radiation ($\lambda = 0.71073$ Å) from an $\text{I}\mu\text{S}$ microsource for the structure of compound **7b**. The structures were solved by direct methods using SHELXS 59 and refined against F^2 on all data by full-matrix least-squares with SHELXL-97 60 following established refinement strategies. 61 All non-hydrogen atoms were refined anisotropically. Except for the two hydrogen atoms on the water molecule in the structure of **7b**, all hydrogen atoms were included in the model at geometrically calculated positions and refined using a riding model. Coordinates for the two water-hydrogen atoms were taken from the difference Fourier analysis, and the hydrogens were subsequently refined semifreely with the help of distance restraints. The isotropic displacement parameters of all hydrogen atoms were fixed to 1.2 times the U value of the atoms they are linked to (1.5 times for methyl groups).

Compounds **2a**, **2b**, and **6b** crystallize in the monoclinic space group $P2_1/c$. Compounds **2a** and **6b** contain one molecule, and **2b** contains two molecules in the asymmetric unit. Compound **2a** contains half a molecule of hexane, which is located near a crystallographic inversion center and disordered accordingly. Compound **2b** contains two molecules of CH_2Cl_2 , one of which is disordered over three positions. Compound **7b** crystallizes in the monoclinic space group $P2_1$ with one molecule of **7b**, its chloride counterion, one water molecule, and one disordered molecule of dichloromethane. The N-bound *n*-hexyl group is heavily disordered and was modeled to be distributed over three independent, mutually exclusive positions. All disorders in all structures were refined with the help of similarity restraints on 1,2 and 1,3 distances and displacement parameters as well as rigid bond restraints for anisotropic displacement parameters.

CCDC 817543–817546 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Computational Details. Ground-state geometries of $[\text{Ir}(\text{ppy})_2(\text{CN}_{\text{trpy}})]$ and $[\text{Ir}(\text{ppy})_2(\text{N}^{\wedge}\text{N}_{\text{tzpy}})]^+$ were optimized by DFT calculations, which were performed using the Gaussian 03 software (Gaussian Inc.)⁶² with a B3LYP exchange-correlation functional and the LANL2DZ basis set under an effective core potential. The initial geometries were based on simplified X-ray structures of **2a** and **6b**, with the hexyl groups replaced with methyl groups and F atoms with H atoms, and optimized without any constraints.
