## Reactions of Halodifluorophosphines with Silver Salts<sup>1</sup>

By GERALD G. FLASKERUD, KENT E. PULLEN, AND JEAN'NE M. SHREEVE

Received October 23, 1968

The reactions of  $\text{PF}_2\text{I}$ ,  $\text{PF}_2\text{Br}$ , or  $\text{PF}_2\text{Cl}$  with silver salts have been shown to provide an excellent route to new  $\text{PF}_2$ -containing compounds. Compounds prepared and characterized are  $\text{CF}_3\text{C}(\text{O})\text{OPF}_2$ ,  $\text{CF}_3\text{CF}_2\text{C}(\text{O})\text{OPF}_2$ ,  $\text{CF}_3\text{CF}_2\text{CF}_2\text{C}(\text{O})\text{OPF}_2$ , and  $\text{CH}_3\text{C}(\text{O})\text{OPF}_2$ . In addition, the previously reported compounds  $\text{PF}_2\text{CN}$  and  $\text{PF}_2\text{NCO}$  are easily prepared by this method.

Recent investigations have shown the utility of using difluoroiodophosphine<sup>2</sup> as a reagent for the syntheses of compounds which contain the  $\text{PF}_2$  moiety. Thus,  $\text{PF}_2\text{I}$  has been found to react with mercury to give tetrafluorodiphosphine,<sup>3</sup> with mercury and hydrogen iodide to give difluorophosphine,<sup>4</sup> with copper(I) oxide to give  $\mu$ -oxo-bisdifluorophosphine,<sup>3</sup> and with copper(I) cyanide to give cyanodifluorophosphine.<sup>3a</sup> With sulfur, iodothiophosphoryl difluoride is formed.<sup>5</sup> Both  $\text{PF}_2\text{I}$  and  $\text{PF}_2\text{Br}$  have been found to add across the carbonyl double bond in hexafluoroacetone,<sup>6</sup> and to react with hydrogen chalcogenides and trimethyltin hydroxide.<sup>7</sup> Chlorodifluorophosphine<sup>8-10</sup> and bromodifluorophosphine<sup>8b,11</sup> have been known for a considerable time, but little of their chemistry has been studied.

Reactions of the halodifluorophosphines with silver

salts at room temperature provide an excellent general route to  $\text{PF}_2\text{X}$  compounds; *e.g.*, the new compounds, trifluoroacetatodifluorophosphine,  $\text{CF}_3\text{C}(\text{O})\text{OPF}_2$ , pentafluoropropionatodifluorophosphine,  $\text{CF}_3\text{CF}_2\text{C}(\text{O})\text{OPF}_2$ , heptafluoro-*n*-butyratodifluorophosphine,  $\text{CF}_3\text{CF}_2\text{CF}_2\text{C}(\text{O})\text{OPF}_2$ , and acetatodifluorophosphine,  $\text{CH}_3\text{C}(\text{O})\text{OPF}_2$ , have been prepared and characterized. The previously reported compounds, cyanodifluorophosphine,<sup>3a</sup>  $\text{PF}_2\text{CN}$ , and isocyanatodifluorophosphine,<sup>12</sup>  $\text{PF}_2\text{NCO}$ , also were readily prepared by this method.

Although the perfluorocarboxylatodifluorophosphines are hydrolyzed rapidly by moisture, they seem to have considerable thermal stability; *e.g.*,  $\text{C}_2\text{F}_5\text{C}(\text{O})\text{OPF}_2$  showed no indication of decarboxylation or decomposition after several days at 150°.

### Experimental Section

**Apparatus.**—A standard Pyrex high-vacuum system was used for manipulation of volatile compounds. Glass stopcocks were lubricated with Kel-F No. 90 grease (3M Co.). Reactions were carried out in 100-ml Pyrex flasks fitted with a Teflon stopcock (Fischer and Porter Co.) and a side arm for admission of the silver salt.

Infrared spectra (Table I) were recorded in the gas phase with a Beckman IR5A or a Perkin-Elmer Model 137 Infracord spectrophotometer. The samples were contained in a Pyrex cell (6-mm path length) equipped with NaCl windows. High-resolution <sup>19</sup>F nmr spectra (Table II) were obtained using a Varian Model

HA-100 spectrometer operating at 94.1 Mc. Trichlorofluoromethane (Matheson Co.) which had been dried over  $\text{P}_4\text{O}_{10}$  or tetramethylsilane was used as an internal reference. Mass spectra (Table III) were obtained with a Hitachi Perkin-Elmer Model RMU-6E spectrometer operating at an ionization potential of 70 eV. Vapor densities were determined by the method of Regnault using a Pyrex bulb equipped with a Teflon stopcock.

Elemental analyses (Table IV) were performed by Alfred Bernhardt Microanalytisches Laboratorium, Max Planck Institut, Mulheim (Ruhr), West Germany.

**Reagents.**— $\text{PF}_2\text{I}$ ,  $\text{PF}_2\text{Br}$ , and  $\text{PF}_2\text{Cl}$  were prepared by the reaction of appropriate hydrogen halide with  $(\text{CH}_3)_2\text{NPF}_2$ ,<sup>2b,10</sup> HI, HBr, and HCl were obtained from the Matheson Co. and were used without further purification.  $\text{CF}_3\text{CO}_2\text{Ag}$  and  $\text{C}_2\text{F}_5\text{CO}_2\text{Ag}$  were obtained from Columbia Organic Chemicals Co.,  $n\text{-C}_3\text{F}_7\text{CO}_2\text{Ag}$  was from Peninsular ChemResearch,  $\text{CH}_3\text{CO}_2\text{Ag}$  was from Allied Chemical Co.,  $\text{AgOCN}$  was from Eastman Organic Chemicals, and  $\text{AgCN}$  was from Fisher Scientific Co. Before use, the silver salts were ground to a fine powder and dried by heating under dynamic vacuum at 100° for 30 min.

**General Procedure.**—Essentially the same method was followed for the preparation of all compounds.  $\text{PF}_2\text{Cl}$ ,  $\text{PF}_2\text{Br}$ , or  $\text{PF}_2\text{I}$  reacted rapidly and nearly quantitatively toward the silver salts used. In a typical reaction,  $\text{PF}_2\text{Cl}$  (3.38 mmol) was condensed onto a slight excess of dry silver trifluoroacetate (4.57 mmol) at  $-183^\circ$  and the reaction bulb was allowed to warm to  $25^\circ$ . That reaction occurred below room temperature was evidenced by a jumping action and a simultaneous color change of the salt. The reaction was complete by the time ambient temperature was reached (10 min). The volatile

by gas chromatography employing a 7 or 11 ft  $\times$  0.25 in. aluminum tube packed with 20% by weight Kel-F No. 3 polymer oil (3M Co.) on acid-washed Chromasorb P (Wilkins Instrument and Research, Inc.). Purification of CH<sub>3</sub>C(O)OPF<sub>2</sub>, PF<sub>2</sub>CN, and PF<sub>2</sub>NCO was brought about by trap-to-trap distillation. Trap temperatures of -60, -78, and -183° were used for CH<sub>3</sub>C(O)OPF<sub>2</sub>; -60, -96, and -183° were used for PF<sub>2</sub>CN and PF<sub>2</sub>NCO. CH<sub>3</sub>C(O)OPF<sub>2</sub> was retained at -78° and PF<sub>2</sub>CN and PF<sub>2</sub>NCO were retained at -95°.

### Results and Discussion

All of the new difluorophosphines at room temperature are colorless, volatile liquids which react readily with water but do not attack glass or mercury. While the R<sub>f</sub>C(O)OPF<sub>2</sub> compounds (R<sub>f</sub> = CF<sub>3</sub>, C<sub>2</sub>F<sub>5</sub>, C<sub>3</sub>F<sub>7</sub>) may be stored at 25° under vacuum for extended periods of time without decomposition, CH<sub>3</sub>C(O)OPF<sub>2</sub> decomposes to a red polymeric material within 24 hr under the same conditions. However, the latter may be transferred in a vacuum system and stored at -183° without polymerization occurring. Because of this thermal instability, the normal boiling point was not determined.

The hydrolysis of each of the RC(O)OPF<sub>2</sub> compounds was followed qualitatively by infrared spectroscopy. The admission of a small amount of moist air into an infrared cell which contained a sample of the pure compound resulted in a spectrum that showed bands attributable to (RC(O))<sub>2</sub>O and PF<sub>2</sub>OPF<sub>2</sub> accompanied by a decrease in the intensity of the original bands. Additional moist air converted the anhydride to RC(O)OH.

Since chloro-, bromo-, and iododifluorophosphines react with these silver salts with equal ease, it is preferable to use either the chloro or bromo compound because of its relatively greater stability. PF<sub>2</sub>I tends to disproportionate into PF<sub>3</sub> and PI<sub>3</sub>.<sup>2</sup>

Characteristic P-F stretching frequencies in the infrared region (Table I) occur in the range from 850 to 900 cm<sup>-1</sup>. In R<sub>f</sub>C(O)OPF<sub>2</sub> (R<sub>f</sub> = CF<sub>3</sub>, C<sub>2</sub>F<sub>5</sub>, and *n*-C<sub>3</sub>F<sub>7</sub>) bands between 1805 and 1809 cm<sup>-1</sup> are due to C=O; while for CH<sub>3</sub>C(O)OPF<sub>2</sub> this band shifts to 1780 cm<sup>-1</sup>. The CF stretching region in R<sub>f</sub>C(O)OPF<sub>2</sub> encompasses a wide range (1000-1400 cm<sup>-1</sup>). The bands in PF<sub>2</sub>NCO may be assigned as follows: 2400 and 2285 cm<sup>-1</sup> NCO pseudoantisymmetric stretch, in and out of phase; 1435 and 1405 cm<sup>-1</sup>, NCO pseudo-symmetric stretch, in and out of phase; 857 cm<sup>-1</sup>, PF<sub>2</sub> stretch; 715 cm<sup>-1</sup>, PNCO deformation, in plane.<sup>13</sup> Since bands occur in the 1400-1500-cm<sup>-1</sup> region and a

cyanate is not expected to have any fundamentals between 1200 and 2000 cm<sup>-1</sup>, the compound formed in the reaction of PF<sub>2</sub>Cl with AgOCN must be the isocyanate PF<sub>2</sub>NCO. The mass spectral evidence below also helps to verify this conclusion. PF<sub>2</sub>CN was identified from its previously reported infrared spectrum.<sup>3a</sup>

The <sup>19</sup>F nmr spectra of R<sub>f</sub>C(O)OPF<sub>2</sub> and RC(O)OPF<sub>2</sub> are consistent with the postulated compounds. Fluorine chemical shifts of PF<sub>2</sub> groups in the region between  $\phi^*$  44 and 50 are analogous to those in ROPF<sub>2</sub> compounds (R = alkyl, phenyl).<sup>14</sup> No spin-spin coupling is observed between fluorine bonded to phosphorus and fluorine or hydrogen in the carboxalato groups. The  $J_{P-F}$  values found are about 1380 cps for the perfluoro compounds and decrease slightly when phosphorus is bonded to NCO or CH<sub>3</sub>C(O)O. This is also observed as fluorine is replaced by less electronegative groups in the series PF<sub>3</sub>, CF<sub>3</sub>PF<sub>2</sub>, and CH<sub>3</sub>PF<sub>2</sub>.<sup>14</sup>

Although molecular ions in the mass spectra (Table III) are observed for all compounds except CF<sub>3</sub>C(O)OPF<sub>2</sub> and CH<sub>3</sub>C(O)OPF<sub>2</sub>, only in the case of PF<sub>2</sub>NCO does this species occur in appreciable relative abundance (59.5). In PF<sub>2</sub>CN, the parent ion is also the second most abundant peak.<sup>3a</sup> The presence of peaks at *m/e* 45 (PN<sup>+</sup>) and *m/e* 64 (PF<sub>2</sub>N<sup>+</sup>) and the absence of *m/e* 85 (PF<sub>2</sub>O<sup>+</sup>) lend support to the infrared evidence that the compound is an isocyanate rather than a cyanate. Existence of peaks at *m/e* 47 (PO<sup>+</sup>) and *m/e* 43 (HNCO) for PF<sub>2</sub>NCO and analogous fragments for the other compounds can arise from hydrolysis, e.g., *m/e* 45 (COOH<sup>+</sup>), *m/e* 135 (PF<sub>2</sub>OPF<sup>+</sup>), and *m/e* 154 (PF<sub>2</sub>OPF<sub>2</sub><sup>+</sup>). Also, for CH<sub>3</sub>C(O)OPF<sub>2</sub>, *m/e* 60 (CH<sub>3</sub>C(O)OH) and for C<sub>2</sub>F<sub>5</sub>C(O)OPF<sub>2</sub> and C<sub>3</sub>F<sub>7</sub>C(O)OPF<sub>2</sub>, *m/e* 86 (HPF<sub>2</sub>O) are observed. Fragmentation patterns for all compounds contain some ions derived from rearrangement, e.g., *m/e* 88 (CF<sub>4</sub><sup>+</sup>, PF<sub>3</sub><sup>+</sup>). For R<sub>f</sub>C(O)OPF<sub>2</sub> (R<sub>f</sub> = CF<sub>3</sub>, C<sub>2</sub>F<sub>5</sub>, C<sub>3</sub>F<sub>7</sub>), fragments, including some which are a result of rearrangement, e.g., CF<sub>2</sub>H<sup>+</sup>, CF<sub>3</sub>CO<sup>+</sup>, and CF<sub>3</sub>CO<sub>2</sub><sup>+</sup>, typically associated with perfluorocarboxylic acids occur.<sup>15</sup>

**Acknowledgments.**—This work was supported in part through a contract with the Office of Naval Research. We are indebted to the National Science and the Max C. Fleischmann Foundations for grants to purchase the HA-100 nmr spectrometer. The authors wish to thank Mr. Leon Zaborowski for the <sup>19</sup>F nmr spectra and Dr. Gary R. Hansen and Mr. Robert Boyd for the mass spectra.
