

Fig. 4.—Mole-ratio study of the osmium(VI)-gluconate system using optical rotation as the measured variable. All solutions contained $2 \times 10^{-8} F$ sodium gluconate and were adjusted to pH 14. The measurements were made in a 40-cm. polarimeter tube. Curve A is for 2-hr. old solutions, curve B for 2-day old solutions, and curve C for 24-day old solutions.

Osmium(IV) to osmium(III); pH 13 to 14

$$Os(GH_4)_2(OH)_{z=3}^{5-z} + e^- \longrightarrow Os(GH_4)_2(OH)_{z=3}^{4-z}$$
 (4)
pH 11 to 13
 $O(GH_4)_2(OH) = b^{-z} + e^-$

 $Os(GH_4)_2(OH)_{z-3}^{b-z} + e^- \xrightarrow{} Os(GH_4)_2(OH)_{z-4}^{b-z} + OH^-$ (5)

pH 8 to 11

 $Os(GH_4)_2(OH)_{y-1}^{3-y} + e^{-} \xrightarrow{} Os(GH_4)_2(OH)_{y-1.5}^{2.5-y} + 0.5OH^{-} (6)$

Consideration of these five equations indicates that $x \ge 4$; $y \ge 1$; $y \le x$.

Under basic conditions it is probable that the osmium complexes would all carry negative charges. Thus, reference to eq. 2 indicates that assuming x = 6 gives a consistent set of equations. Also, these same conditions indicate that it is consistent to assume y = 5.

In summary gluconate ion forms strong complexes with osmium(VI, IV, III) in alkaline solutions. Advantage can be taken of these complexes as a means for stabilizing the ions in solution and also as a polarographic method of analysis. The use of sodium gluconate plus NaOH as a supporting electrolyte has the advantage that osmium(VIII) is spontaneously and quickly reduced to osmium(VI) by the gluconate. The resulting osmium(VI) gives a well defined and analytically useful reduction wave over a wide concentration range.

Preparation and Properties of Several Ammonium Uranium(IV) and Ammonium Plutonium(IV) Fluorides¹

BY R. BENZ, R. M. DOUGLASS, F. H. KRUSE, AND R. A. PENNEMAN

Received November 30, 1962

A series of anhydrous fluoride complexes is formed between NH₄F and actinide tetrafluorides. Compounds with NH₄F: MF₄ (M = U or Pu) mole ratios of 4:1, 2:1, 7:6, 1:1, and 1:3 were prepared by reaction of stoichiometric quantities in sealed tubes or by gravimetric arrests during NH₄F distillation. X-Ray powder diffraction data are presented. Corresponding U(IV) and Pu(IV) compounds are isostructural. The 7NH₄F 6MF₄ compounds are rhombohedral, $a_0 = 9.55$ and 9.42 Å., $\alpha = 107.4^{\circ}$ and 107.4° for M = U and Pu, respectively. A method of chemical analysis for NH₄, U, and F on a single sample was developed using pyrohydrolysis, ion exchange, and volumetric techniques.

Introduction

The extensive studies of compounds formed in melts containing UF₄ and the alkali fluorides have been reviewed by Thoma,² who noted that several compound types are common: $3MF \cdot UF_4$, $2MF \cdot UF_4$, $7MF \cdot 6UF_4$, and $MF \cdot UF_4$. Only one corresponding compound in the NH_4F - UF_4 and NH_4F - PuF_4 systems has been reported, " NH_4PuF_6 "; the occurrence of $NH_4F \cdot PuF_4$ and $7NH_4F \cdot 6PuF_4$ as separate compounds was not noted.³⁻⁸ Prior work with ammonium fluoride complexes of U(IV) and Pu(IV) obtained by precipitation from aqueous solution or by treatment of the dioxide with NH_4HF_2 often has contained errors, primarily from the lack of recognition that "drying" can result in loss of NH_4F . Furthermore, NH_4F loss has been confused with loss of hydrate water (note the near coincidence of the formula weights of NH_4F , 37, and $2H_2O$, 36).

The direct reaction of actinide tetrafluorides with NH_4F under anhydrous conditions has not been re-

Fig. 1.—Thermal decomposition of compounds in the NH₄F-UF₄ system.

ported. Two difficulties in the direct reaction are that certain proportions reach equilibrium only sluggishly at temperatures as high as 300° and that above 400° NH₄F reduces PuF₄. These difficulties are avoided by *first* treating the tetrafluoride with sufficient NH₄F to form (NH₄)₄UF₈ and (NH₄)₄PuF₈; equilibrium is reached rapidly even at *ca*. 100°. This product then is easily converted to other compounds by distillation of the excess NH₄F.

Using this technique we have prepared a series of NH_4F-UF_4 and NH_4F-PuF_4 compounds. The compounds were characterized by thermogravimetric, X-ray powder diffraction, and chemical analysis.

Experimental

Materials.—Finely divided UF₄ (99.9%) and PuF₄ (99.9%) were used. Baker and Adamson Reagent NH₄F was dried 1 hr. at 130° in a partially covered platinum crucible and then ground to a fine powder. Argon (99.99%), helium (99.7%), and oxygen (99.5%) were dried in a -80° cold trap. Dry gases were used in order to avoid hydration and hydrolysis of the tetrafluorides.

General Procedure for Compound Preparation.—The reaction of NH₄F with UF₄ to yield complex fluorides proceeds readily at $80-130^{\circ}$ at all mole ratios from 1:1 to 4:1. With PuF₄ the reaction did not proceed rapidly when the NH₄F:PuF₄ ratio was below 2:1. In most cases, however, equilibrium was reached from both directions, the identical compound being prepared by direct reaction (NH₄F + MF₄) as well as by decomposition of a phase richer in NH₄F. For the preparations at 80° , tightly closed polyethylene or Teflon bottles were used. At 130° and above, screw-cap containers of Dural were satisfactory.

Typical Procedure for Thermogravimetric Analysis.—For the preparation of the 4:1 compound, 10 g. of MF₄ was weighed into a platinum or nickel crucible. Five g. of NH_4F (a slight excess over 4:1) then was added and the two fine powders were mixed thoroughly. Weighing was done in a glove box provided with recirculated and dried air. The crucible was covered and placed in a horizontal 2-in. diameter nickel tube closed at one end and surrounded by a tube furnace provided with automatic temperature control. Temperature readings were taken with a thermo-

couple located on the nickel tube. The covered crucible was heated 1 hr. at 130° (1 hr. at 130° or 6 hr. at 70° was sufficient to form the 4:1 compound). After cooling, the product was weighed, reground, and mixed thoroughly. When a starting mole ratio of 2:1 was used, the mole ratio was adjusted to exactly 2:1.

During the thermogravimetric runs, the sample was maintained at a constant temperature under vacuum or in a stream of dry argon, helium, oxygen, or air at atmospheric pressure. The crucible was cooled and weighed periodically. After each weighing, the sample was mixed thoroughly. At arrests, a portion was taken for X-ray diffraction and chemical analysis.

Compounds in the NH₄**F**-**UF**₄ **System**.—Typical decomposition curves for compounds in the NH₄F-UF₄ system are illustrated in Fig. 1. Arrests in the decomposition curves were reproducible within 0.3% of the stoichiometric weight independent of whether NH₄F removal was effected under vacuum, argon, helium, or air. Five complex compounds forming seven distinct phases were found.

 $(NH_4)_4UF_8$.—Non-stationary arrests were obtained for this compound in a partially covered crucible in air at 60–90°. For preparative purposes, formation proceeds readily at 80–130° in a sealed plastic tube containing a mixture of NH₄F and UF₄ in 4:1 mole ratio. After heating the mixture for 3–6 hr., the container is cooled to room temperature before opening to avoid loss of NH₄F. Fine-grain crystals are pea green; large crystals are emerald green.⁹

 $(NH_4)_2UF_6$.—Stationary arrests were obtained for this compound in air at 110–130°. Decomposition (loss of NH₄F) becomes appreciable under vacuum at 150–170°. The compound is readily formed from NH₄F and UF₄ by heating 2:1 mixtures at 80–130° for 3–6 hr. in a sealed tube. Fine-grain crystals are blue-green.

 $7NH_4F.6UF_4$.—Stationary arrests were obtained for this compound in helium at 200-220°; a non-stationary arrest was obtained under vacuum at 180°. This compound also is obtained on heating NH₄F and UF₄ in 7:6 mole ratio at 80-100° in, a sealed tube for 3-6 hr. Prepared in this way, no NH₄F loss was detected from a 10-g. sample on subsequent heating for 24 hr. at 92° under vacuum (1 μ) over a liquid nitrogen trap. Fine-grain crystals are light green.

 α -**NH**₄**UF**₅.—This phase may be regarded as an NH₄F-*deficient* form of the 7:6 compound from which it was not distinguishable by X-ray powder techniques. This 1:1 phase invariably was produced on direct reaction of NH₄F with UF₄ in 1:1 mole ratio at 80–200°. Annealing in a sealed capsule at 190° for 30 days produced partial conversion to β -1:1. It is likely that a single phase of variable composition exists between the 7:6 and 1:1 stoichiometries. However, at 150° the 1:1 composition has a special stability with respect to compositions slightly richer or poorer in NH₄F: removal of NH₄F under vacuum from the 7:6 phase proceeds smoothly until the 1:1 composition (α form) is reached at which point the rate of NH₄F from the 7:6 phase gives either the β or γ form of 1:1 or gives no stationary arrest at the 1:1 composition. Fine-grain crystals are light green.

 β -NH₄UF₅.—Stationary arrests were obtained for this phase under vacuum at 180–210° starting with either the 4:1 or 2:1 compound. Fine-grain crystals are green to blue-green.

 γ -**NH**₄**UF**₅.---Stationary arrests were obtained for this phase on decomposition under vacuum at 150° of the 2:1 compound (prepared at 80°). Fine-grain crystals are light blue-green.

 $\rm NH_4F \cdot 3UF_4$.—Arrests were obtained for this compound under vacuum at 270–290°. This compound decomposes to pure UF₄ under vacuum at 300–400° as shown by weight changes and X-ray powder patterns of the product. An attempt was made to produce the 1:3 compound by direct reaction of NH₄F and UF₄ at 270° for 40 hr. in a sealed Dural container, but the product

⁽⁹⁾ In a study (to be published) of the NH₄F-UF₄-H₂O system, we find that large crystals, giving the same X-ray powder pattern and chemical analysis as the anhydrous 4:1 preparation, are readily obtained by equilibration of 2.5 wt. % UF₄ with 40% aqueous NH₄F at 25°.

gave an X-ray powder pattern showing only lines of UF₄ and α -1:1. Fine-grain crystals are green.

Compounds in the NH₄F-PuF₄ System.—Typical decomposition curves for compounds in the NH₄F-PuF₄ system are illustrated in Fig. 2. Arrests in the decomposition curves were reproducible within 0.3% of the stoichiometric weight independent of whether NH₄F removal was effected under vacuum, argon, helium, oxygen, or air. (Results in helium and argon are essentially the same as in air and are not shown.) Five complex compounds forming seven distinct phases were found.

 $(NH_4)_4 PuF_8$.—Non-stationary arrests were obtained for this compound in air at 70–100°. It is not hygroscopic at 70° in water-saturated helium. For preparative purposes, a 4:1 mixture of NH₄F and PuF₄ reacts to form this compound in a sealed tube at 80–130° in 6 hr. Crystals vary in color from light red to pink, depending on crystal size.

 $(\mathbf{NH}_4)_2\mathbf{PuF}_6$.—Stationary arrests were obtained for this compound in air at 130–160° and under vacuum at 130°. It is not hygroscopic at 70°. The 2:1 compound also is formed by reaction of NH₄F and PuF₄ in 2:1 mole ratio in a sealed tube at 80–130° for 6 hr. Fine-grain crystals are green. Coarse crystals are prismatic and optically biaxial negative with optic axial angle *ca*. 60°. They exhibit parallel extinction, positive elongation, and strong pleochroism with X and Y colorless, Z green; extreme refractive indices are 1.484 \pm 0.005, 1.500 \pm 0.005. Polysynthetic twinning is common.

 $7NH_4F \cdot 6PuF_4$.—Stationary arrests were obtained for this compound in air or under vacuum at 200–230° starting with either the 4:1 or 2:1 compound. Direct reaction of NH₄F and PuF₄ in 7:6 mole ratio is sluggish and did not produce the 7:6 phase after 6 hr. at 80°. Fine-grain crystals are light brown to orange.

 α -NH₄PuF₅.—This phase may be regarded as an NH₄F-deficient form of the 7:6 compound from which it is indistinguishable by X-ray powder techniques. It is formed by annealing 1:1 mixtures of NH₄F and PuF₄ in a sealed tube for 1 day at 220°. Partial conversion of β -1:1 to α -1:1 was observed at 220° in 2 weeks, Partial conversion of α -1:1 to β -1:1 was observed at 270° in 1 week. Fine-grain crystals are light brown to orange.

 β -NH₄PuF₅.—Crystals were obtained in nine different runs involving thermal decomposition of the 2:1 compound in oxygen at 180–200°. The compound is not hygroscopic at 70°. Finegrain crystals are yellow-green to light green.

 γ -NH₄PuF₅.—Stationary arrests were obtained for this compound in air, oxygen, or under vacuum at 190–230°. Decomposition of 4:1 or 2:1 compounds usually gave γ -1:1 rather than β -1:1. Fine-grain crystals are orange to light brown. The crystals are optically biaxial positive with large optic axial angle, and strongly pleochroic with X colorless, Z olive drab.

NH₄F·3PuF₄.—A stationary arrest was obtained from β -1:1 in oxygen at 220°. Starting with γ -1:1, non-stationary arrests usually were obtained at the 1:3 composition at 280-290°. X-Ray powder patterns from these samples confirmed the presence of the 1:3 phase by comparison with the corresponding uranium compound. Crystals decompose slowly under vacuum at 300-330° to very nearly pure PuF₄ as shown by weight changes and X-ray powder patterns. A small fraction of the PuF₄ was consumed in a slow, unidentified side reaction at these temperatures. Fine-grain crystals are pink.

Chemical Analysis of Phases.—Plutonium was determined by titration with cerium. Ammonia was determined by the Kjeldahl method.

For most of the uranium samples, we extended a pyrohydrolysis method to allow determination of NH₄, U, and F on a single sample. A sample containing 3–4 mequiv. of total fluoride was weighed into a platinum beat and heated progressively to 1000° in a stream of superheated steam in a pyrohydrolysis apparatus.¹⁰ The residue in the boat was weighed as U₂O₈. The condensate containing NH₄F and HF was caught in a plastic

(10) J. C. Warf, W. D. Cline, and R. Tevebaugh. Anal. Chem., 26, 342 (1954).

Fig. 2.—Thermal decomposition of compounds in the NH₄F-PuF₄ system.

beaker and titrated to the methyl red end point with 0.1 M NaOH. This procedure gives only fluoride equivalent to UF₄ as found by Alford.^{3d} Our extension of his procedure was to pass the solution, after titration, through Dowex-50 resin (100-200 mesh) contained in plastic tubing. The H⁺-form resin converted the NH₄F and the NaF (resulting from the first titration) into HF. A second titration was made to the phenolphthalein end point, giving total fluoride. The difference between the first and second titrations gave NH₄ (e.g., in the case of (NH₄)₄UF₈ the second titer is twice the first). To check the combined method, we used crystallographically pure (NH₄)₈UO₂F₅ and obtained: first titration, F/U = 2.04 (theoretical, 2); second titration, F/U = 5.00 (theoretical, 5); (second titration — first titration) $= NH_4/U = 2.96$ (theoretical, 3).

Typical data for $NH_4F:MF_4$ (M = U or Pu) mole ratios in the various phases as determined by thermogravimetric and chemical analyses are compared in Table I. Data from X-ray powder diffraction studies of the pure phases are listed in Tables II, III, and IV.

Discussion

We have shown that the direct reaction of NH₄F with UF_4 or PuF_4 yields a series of complex fluorides. Analogous reactions between UF5 and NH4F also have been reported recently.¹¹ In contrast, no compound consisting of NH₄F and PuF₃ could be detected using techniques described above. The 4:1 compounds, $(NH_4)_4$ - UF_8 and $(NH_4)_4PuF_8$, are the least stable in the NH_4F- UF4 and NH4F-PuF4 systems. Nevertheless, in the $NH_4F-UF_4-H_2O$ system⁹ anhydrous $(NH_4)_4UF_8$ is the stable crystalline phase over wide ranges of NH₄F concentration.

In the NH₄F–UF₄ system, the 4:1 compound is the highest complex formed, whereas in the alkali fluoride- UF_4 series² it is found only between LiF and UF_4 .¹² Loss of NH₄F from the 4:1 compounds yields the 2:1 compounds without evidence for 3:1 or other intermediate compounds. As the ionic radii of NH_4^+ and Rb⁺ are nearly the same,¹³ it is of particular interest to

compare the series of compounds in the RbF-UF4¹⁴ and NH₄F–UF₄ systems: 3RbF·UF₄, 2RbF·UF₄, 7RbF· 6UF4, RbF·UF4, and RbF·3UF4 vs. 4NH4F·UF4, $2NH_4F \cdot UF_4$, $7NH_4F \cdot 6UF_4$, $NH_4F \cdot UF_4$, and $NH_4F \cdot$ 3UF₄. The 4:1 compound occurs in the NH₄F-UF₄, NH₄F-PuF₄, and NH₄F-AmF₄ systems,¹⁵ whereas the 3:1 compound is missing. The 2:1 compound occurs in both the rubidium and ammonium systems but the compounds are not isostructural.¹⁶ However, corresponding ammonium and rubidium uranium(IV) fluoride compounds are isostructural in the case of 7NH₄F·6UF₄ and 7RbF·6UF₄.

In earlier work, a pink NH₄F-PuF₄ compound was assigned the formula $(NH_4)_2PuF_6$ by Alenchikova, et al.,6 based on analysis of "dried" material. However, this pink compound is undoubtedly $(NH_4)_4PuF_8$, which readily loses two molecules of NH4F forming green (NH₄)₂PuF₆. Alenchikova, et al.,⁶ also prepared a green NH4F-PuF4 compound which, although it was not analyzed, they stated "probably" had the formula NH₄PuF₅. Their X-ray powder data for this phase correspond with our data for $(NH_4)_2PuF_6$.

TABLE IV

Partial X-Ray Powder Patterns of β -1:1, γ -1:1, and 1:3

Galkin, Sudarikov, and Zaitsev⁸ concluded that solid NH₄F–UF₄ mixtures decompose in three steps: NH₄UF₅ (10% excess NH₄F) $\xrightarrow{220-280^{\circ}}$ NH₄UF₅ $\xrightarrow{320-360^{\circ}}$ HUF₅ $\xrightarrow{420-450^{\circ}}$ UF₄ when heated at a linear rate up to *ca.* 600°. They found percentage-weight losses which correspond very nearly to the values which we obtained for the series: (NH₄)₂UF₆ $\xrightarrow{180^{\circ}}$ NH₄UF₅ $\xrightarrow{290^{\circ}}$ NH₄F $3UF_4 \xrightarrow{400^{\circ}}$ UF₄ illustrated in Fig. 1. The decomposition scheme is probably the same in both cases. We found no evidence for the existence of their suggested compound "HUF₅."

Maly, et al.,⁷ have carried out thermogravimetric analyses on very small (mg.) quantities of products obtained by reaction of PuO_2 with NH_4HF_2 . Our results suggest that the arrest which they attribute to "dark green $NH_4PuF_5 \cdot 2H_2O$ " was due instead to the green compound $(NH_4)_2PuF_6$. Their decomposition curve also indicates an arrest at the weight near that of $NH_4F \cdot 3PuF_4$ that they did not point out.

The X-ray powder patterns of the 7:6 and α -1:1 phases could be indexed in the R $\overline{3}$ space group assigned to similar members of the alkali fluoride-UF₄ series. The lattice dimensions derived are: 7NH₄F·6UF₄ and α -NH₄F·UF₄, $a_0 = 9.55$ Å., $\alpha = 107.4^{\circ}$ (hexagonal dimensions $a_0 = 15.40$, $c_0 = 10.49$ Å.); 7NH₄F·6PuF₄ and α -NH₄F·PuF₄, $a_0 = 9.42$ Å., $\alpha = 107.4^{\circ}$ (hexagonal dimensions $a_0 = 15.18$, $c_0 = 10.36$ Å.). The preparations were too fine-grained to permit confirmation of symmetry by optical-microscopic methods.

Acknowledgments.—The authors thank G. R. Waterbury and E. G. Bosier for some chemical analyses and D. F. Bowersox for some plutonium preparations.

The Effect of Pressure upon the Optical Activity of Crystalline Inorganic Compounds

BY J. BRADY, F. DACHILLE, AND C. D. SCHMULBACH

Received October 29, 1962

Extreme pressures of 10,000 to 40,000 atmospheres were found to increase the rate of racemization of potassium trioxalatocobaltate(III) in the solid state. The volume of activation, ΔV^* , for the racemization process was determined experimentally and found to be -1.44 ± 0.23 and 1.80 ± 0.28 cm.³/mole for two independent experiments. These data are consistent with an intramolecular mechanism. An intramolecular process that does not include metal-oxygen bond rupture and re-formation is preferred. The mechanism is discussed in terms of the possible structures for the transition state and the relationship of structure to ΔV^* . Approximate values of $4.7 \pm 1.1 \times 10^{-4}$ and $2.11 \pm 0.93 \times 10^{-4}$ hr.⁻¹ for the specific rate constant for racemization of $K_3[Co(C_2O_4)_3]$ at zero pressure were obtained.

Introduction

Despite the observation that the optically active salts, potassium trioxalatocobaltate(III) and potassium trioxalatochromate(III), undergo slow racemization in the solid state,¹ there has been little experimental work centered on this phenomenon and the theoretical impli-

cations arising from it. The study of isotope exchange in aqueous solution for the systems $Co(C_2O_4)_3^{3--*}C_2^{-}O_4^{2-2a}$ and $Cr(C_2O_4)_3^{3--*}C_2O_4^{2-2b}$ showed no interchange under conditions that lead to racemization. These results immediately suggest an intramolecular rearrangement that may or may not involve bond
