

## Importance of Ion Association in the Induced Reactions of Cobalt(III)-Acido Complexes. 2.<sup>1</sup> Nitrosation of the $(\text{NH}_3)_5\text{CoN}_3^{2+}$ Ion

DAVID A. BUCKINGHAM,\* CHARLES R. CLARK, and WAYNE S. WEBLEY

Received November 17, 1981

The nitrosation of  $(\text{NH}_3)_5\text{CoN}_3^{2+}$  ( $\text{CoN}_3^{2+}$ ) in the presence of added anions  $\text{Y}^- = \text{Cl}, \text{NO}_3, \text{ClO}_4$  follows the rate law  $-\text{d}[\text{CoN}_3^{2+}]/\text{d}t = (k_0 + k_1[\text{Y}^-])[\text{H}^+][\text{HNO}_2][\text{CoN}_3^{2+}]$  with  $k_0 = 6.6 \times 10^2 \text{ mol}^{-2} \text{ dm}^6 \text{ s}^{-1}$  and  $k_1 = 1.70 \times 10^5$  (Cl),  $4.48 \times 10^3$  ( $\text{NO}_3$ ),  $2.21 \times 10^3$  ( $\text{ClO}_4$ )  $\text{mol}^{-3} \text{ dm}^9 \text{ s}^{-1}$  at 25.0 °C and  $I = 1.0 \text{ mol dm}^{-3}$  ( $\text{NaSO}_3\text{CF}_3$ ). The rate is little affected by the ionic strength ( $I > 0.2 \text{ mol dm}^{-3}$ ) and  $\text{Y}^- = \text{CF}_3\text{SO}_3^-$  does not affect the rate. The kinetic data are interpreted in terms of  $\text{NO}^+(\text{aq})$  and  $\text{YNO}$  reacting with  $\text{CoN}_3^{2+}$  with respective second-order rate constants of  $3.3 \times 10^9$  and  $1.9 \times 10^8$  (Cl),  $3.5 \times 10^7$  (Br)  $\text{mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$ .  $\text{Y}^-$  species ( $\text{Cl}^-, \text{NO}_3^-$ ) are included in the products of the reaction (as  $\text{CoY}^{2+}$ ), but not via the  $\text{YNO}$  species, and the  $[\text{CoY}^{2+}]/[\text{CoOH}_2^{3+}]$  ratios at variable and constant  $I$  are interpreted in terms of competition between  $\text{Cl}^-, \text{NO}_3^-, \text{ClO}_4^-$  and  $\text{CF}_3\text{SO}_3^-$  ( $\text{NO}_3^- > \text{ClO}_4^- > \text{Cl}^- > \text{CF}_3\text{SO}_3^-$ ) from within the ion-paired  $\text{Y}^-, \text{CoN}_3\text{ONY}^{2+}$  intermediates. For  $\text{Y}^- = \text{Cl}, \text{NO}_3$  this species leads to 40%  $\text{CoCl}^{2+}/60\%$   $\text{CoOH}_2^{3+}$  and 56%  $\text{CoNO}_3^{2+}/44\%$   $\text{CoOH}_2^{3+}$  entry, respectively. Comment is made on the lifetime of the  $\text{Y}^-, \text{CoN}_3\text{ONY}^{2+}$  intermediate, and comparisons are made with oxidative processes involving  $\text{Cl}_2, \text{H}_2\text{O}_2$ , and  $\text{HOCl}$ .

### Introduction

The recent kinetic and product studies on the  $\text{Hg}^{2+}$ - and  $\text{NO}^+$ -induced reactions of  $\text{CoCl}^{2+}$  and  $\text{CoN}_3^{2+}$  ( $\text{Co} = (\text{NH}_3)_5\text{Co}^{3+}$ )<sup>2b</sup> have highlighted the difficulty in obtaining unique mechanistic solutions to these classic dissociative processes. Initially, Posey and Taube<sup>3</sup> interpreted the common  $\text{H}_2^{18}\text{O}/\text{H}_2^{16}\text{O}$  fractionation results for the  $\text{CoX}^{2+} + \text{Hg}^{2+}$  reactions ( $\text{X} = \text{Cl}, \text{Br}, \text{I}$ ) in terms of a limiting dissociative process ( $\text{S}_{\text{N}}1$  (lim), or D). However this agreement was seen as fortuitous since the spontaneous aquations gave the same result<sup>4</sup> and there was other evidence to indicate that these reactions were indeed different.<sup>5</sup> Subsequently, agreement between the  $\text{NO}_3^-$  competition numbers for the various  $\text{CoX}^{2+} + \text{NO}^+$  reactions ( $\text{X} = \text{N}_3, \text{OCONH}_2, \text{NCO}$ )<sup>6,7</sup> and possibly the  $\text{NO}_3^-$ -independent part of the  $\text{CoX}^{2+} + \text{Hg}^{2+}$  reaction,<sup>6</sup> and the common retention of stereochemistry in both,<sup>8</sup> led to a resurgence in the idea that the rapid induced reactions of cobalt(III)-acido complexes were of the limiting dissociative type with the same 5-coordinate intermediate,  $\text{Co}^{3+}$ , competing for the various species in solution. Recent investigations have continued to emphasize this view.<sup>2,7,9</sup>

Reynolds and Alton<sup>2a</sup> showed that in the presence of  $\text{NO}_3^-$  and at constant ionic strength ( $I = 1.0 \text{ mol dm}^{-3}$ ,  $\text{ClO}_4^-$  added) the  $\text{Hg}^{2+}$ -induced process

follows the rate law

$$-\text{d}[\text{CoCl}^{2+}]/\text{d}t = k[\text{CoCl}^{2+}][\text{Hg}^{2+}]$$

where

$$k = k_0' + k_1'[\text{NO}_3^-] \quad (2)$$

They interpreted the  $\text{CoNO}_3^{2+}$  product as deriving substantially from the  $\text{NO}_3^-$  part of the rate law, i.e., via a  $\text{NO}_3^-$  ion pair or directly via  $\text{HgNO}_3^+$ . However Jackson, Lawrance,

and Sargeson<sup>2b</sup> correctly pointed out that this was not a unique solution and that the  $\text{CoNO}_3^{2+}$  product could equally well arise from events occurring subsequent to the rate-determining step with contributions arising from both  $k_1'$  and  $k_0'$  paths, with the ratio of  $\text{CoNO}_3^{2+}/\text{CoOH}_2^{3+}$  formed from either path being dependent on or independent of  $[\text{NO}_3^-]$ . The latter investigators also showed that the observed rate follows (2) for the  $\text{NO}^+$ -induced reaction (3) and pointed out that only at very

low  $\text{NO}_3^-$  concentrations ( $< 0.1 \text{ mol dm}^{-3}$ ) would a clear distinction between the various mechanistic schemes for entry of  $\text{NO}_3^-$  be possible. However, provided the direct insertion possibility for the  $k_1'$  path of the  $\text{Hg}^{2+}$ -induced reaction was accepted, some measure of agreement was obtained for the product ratios arising from the  $k_0'$  paths for both reactions and the  $k_1'$  path for the  $\text{NO}^+$  reaction.

We have used a different interpretation of the  $\text{NO}_3^-$  competition data in a study of the  $\text{Hg}^{2+}$ - and  $\text{NO}^+$ -induced aquations of the  $t\text{-}[\text{Co}(\text{tren})(\text{NH}_3)\text{X}]^{2+}$  ions ( $\text{X} = \text{Cl}, \text{N}_3$ ).<sup>10</sup> Here it was apparent that for the anion-dependent terms in the rate<sup>11</sup>  $\text{NO}_3^-$ -dependent, and at higher concentrations  $\text{NO}_3^-$ -independent,  $\text{CoNO}_3^{2+}$  production was involved and that the limiting  $\text{CoNO}_3^{2+}/\text{CoOH}_2^{3+}$  ratios were different for the two reactions. Furthermore it was possible to interpret the products in terms of a single equilibrium, and this suggested to us that they were derived from some sort of association between  $\text{NO}_3^-$  and the product-determining species. Although free entry from the bulk phase was thus eliminated, it was not possible to determine whether this equilibrium involved the reactant complex or a subsequent intermediate, including the elusive 5-coordinate species. Furthermore, the catalysis afforded by  $\text{ClO}_4^-$  suggested that the true anion-independent rate (given as  $k_0'$  above) was probably less significant than had been previously realized.

One obvious possibility is that the equilibrium results from ion pairing, and any realistic appraisal of anion/cation association in aqueous solution predicts appreciable amounts of ion-paired species in these systems at 0.1–1.0  $\text{mol dm}^{-3}$  electrolyte. If the Fuoss equation<sup>12,13</sup> is accepted, this simple

<sup>a</sup>  $I$  variable. <sup>b</sup>  $I$  constant.

Scheme I

electrostatic treatment gives  $K_{ip}$  (thermodynamic) values of  $\sim 30\ \text{mol}^{-1}\ \text{dm}^3$  for a  $3+/1-$  species, and  $5-8\ \text{mol}^{-1}\ \text{dm}^3$  for a  $2+/1-$  species.<sup>14</sup> Other approximate methods based on osmotic pressure coefficients for completely dissociated electrolytes give  $K_{ip}$  values of a similar magnitude.<sup>15</sup> The possibility that these large amine complexes are not as strongly hydrated as simple aqua ions, and that polarizability effects now become significant, would suggest that ion pairing for the complex ions is at least as large as the above theoretical values. The question is not whether ion pairs  $\text{CoX}^{2+}, \text{Y}^-$  exist but whether they are directly involved in the substitution process. We believe that they are and in recent years have obtained some evidence in support of this belief.<sup>16</sup> Certainly there is good evidence of their involvement in nonaqueous environments.<sup>17</sup>

When studies are carried out in a supporting electrolyte to maintain ionic strength (e.g.,  $[\text{Y}^-] + [\text{ClO}_4^-] = 1\ \text{mol}\ \text{dm}^{-3}$ ), the possibility of a reactive ion pair with the supporting electrolyte arises (Scheme I). For this scheme the rate expression (4) holds and  $\text{Y}^-$  independence in the rate simply

$$k = \{k^*_0 + (k^*_y K^c_{\text{Y}^-} - k^*_{\text{ClO}_4} K^c_{\text{ClO}_4}) \times [\text{Y}^-] + k^*_{\text{ClO}_4} K^c_{\text{ClO}_4}\} / \{1 + (K^c_{\text{Y}^-} - K^c_{\text{ClO}_4})[\text{Y}^-] + K^c_{\text{ClO}_4}\} \quad (4)$$

means that  $K^c_{\text{Y}^-} \approx K^c_{\text{ClO}_4}$  and  $k_y \approx k_{\text{ClO}_4}$ . This allows  $\text{Y}^-$  (i.e.,  $\text{NO}_3^-$ ) to be present in the activated complex without being apparent in the rate. Conversely, a  $\text{Y}^-$  dependence in the rate (i.e., the  $k'_1$  term in (2)) could mean that  $K^c_{\text{Y}^-} k_y \neq K^c_{\text{ClO}_4} k_{\text{ClO}_4}$  or that a more specific type of interaction such as with  $\text{HgY}^+$  or  $\text{YNO}$  is involved. The catalysis by  $\text{ClO}_4^-$  alluded to above<sup>11</sup> indicates an unusually important involvement by anions in the activated complex of the  $\text{Hg}^{2+}$ - and  $\text{NO}^+$ -induced reactions.

With these thoughts in mind we have looked again at the  $\text{CoN}_3^{2+} + \text{NO}^+$  reaction, eq 3, and herein report our observations.

### Experimental Section

$[\text{Co}(\text{NH}_3)_5\text{N}_3](\text{ClO}_4)_2$  was prepared as described previously<sup>2b</sup> and analyzed satisfactorily. All chemicals used were of Analytical reagent

grade except  $\text{NaNO}_2$ , which was BDH Laboratory grade.  $\text{NaCF}_3\text{SO}_3$  was prepared from trifluoromethanesulfonic acid and  $\text{NaOH}(\text{aq})$ , recrystallized from acetone/ether and dried under vacuum.

**Kinetic Measurements.** The rate of nitrosation of  $[\text{Co}(\text{NH}_3)_5\text{N}_3]^{2+}$  was followed spectrophotometrically with either a Cary 219 spectrophotometer or a Durrum D110 stopped-flow spectrophotometer thermostated at  $25.0 \pm 0.1\ ^\circ\text{C}$ . The absorbance change at 330 nm or (mostly) at 516 nm was monitored ( $\epsilon_{330}(\text{CON}_3^{2+})$  281;  $\epsilon_{516}(\text{CoOH}_2^{3+})$  42.4). With the former instrument a hand-operated stopped-flow mixing device connected to a 1-cm flowthrough cell was used. In all cases equal volumes of freshly prepared  $\text{CoN}_3^{2+}$  and  $\text{NaNO}_2$  solutions were premixed and used as one reagent. The other solution was prepared from appropriate mixtures of  $2.0\ \text{mol}\ \text{dm}^{-3}$   $\text{NaClO}_4$ ,  $\text{NaCl}$ ,  $\text{NaCF}_3\text{SO}_3$ , or  $\text{NaNO}_3$ ,  $1.87 \times 10^{-3}\ \text{mol}\ \text{dm}^{-3}$  (Cary) or  $1.6 \times 10^{-2}\ \text{mol}\ \text{dm}^{-3}$  (Durrum) in  $\text{HClO}_4$ , or mixtures of these with  $\text{HClO}_4$  (variable ionic strength). Final experimental conditions are given in Table I. In all cases  $[\text{H}^+]_T$  and  $[\text{NO}_2^-]_T$  exceeded  $[\text{Co}]$  by at least a factor of 10 and first-order kinetics was observed ( $\log(D_t - D_\infty)$  vs.  $t$  plots) for at least 3 half-lives.

**Competitive Experiments. Nitrate Competition.** The azido complex ( $0.15-0.28\ \text{mmol}$ ) was accurately weighed into a  $50\text{-cm}^3$  beaker and dissolved in  $20.0\ \text{cm}^3$  of  $\text{H}_2\text{O}$  or  $0.04\ \text{mol}\ \text{dm}^{-3}$   $\text{HClO}_4$  or  $\text{HNO}_3$  (pipet). A  $20.0\text{-cm}^3$  appropriate mixture (pipets) of  $2.0\ \text{mol}\ \text{dm}^{-3}$   $\text{NaNO}_3/0.04\ \text{mol}\ \text{dm}^{-3}$   $\text{HNO}_3$  and  $2.0\ \text{mol}\ \text{dm}^{-3}$   $\text{NaClO}_4/0.04\ \text{mol}\ \text{dm}^{-3}$   $\text{HClO}_4$  in a second  $50\text{-cm}^3$  beaker was added to the stirred solution followed immediately by ca. 30 mg (0.5 mmol) of solid  $\text{NaNO}_2$  all at room temperature (ca.  $20\ ^\circ\text{C}$ ). Liberation of  $\text{N}_2 + \text{N}_2\text{O}$  was immediate. After about 2 min, further solid  $\text{NaNO}_2$  (15-30 mg) was added to ensure complete reaction, and after 5 min, the solution was diluted with water and ice to ca.  $100\ \text{cm}^3$  and sorbed onto Dowex 50-WX2 cation-exchange resin packed in a  $12\ \text{cm} \times 0.8\ \text{cm}$  column preequilibrated at  $5\ ^\circ\text{C}$  all in a Isco refrigerated cabinet. For the higher  $\text{NO}_3^-$  runs ( $>0.7\ \text{mol}\ \text{dm}^{-3}$ ) some  $[\text{Co}(\text{NH}_3)_5\text{N}(\text{NO}_3)](\text{NO}_3)_2$  precipitated during the latter stages of the reaction, but this was easily redissolved during transference and dilution. The  $\text{CoNO}_3^{2+}$  band was eluted with  $1\ \text{mol}\ \text{dm}^{-3}$   $\text{NaCl}$ , and  $\text{CoOH}_2^{3+}$  was subsequently eluted with  $2\ \text{mol}\ \text{dm}^{-3}$   $\text{HCl}$ , both at  $5\ ^\circ\text{C}$ ; the volumes ( $100-200\ \text{cm}^3$ ) were recorded and absorbances (10- and 5-cm cells) measured promptly (Cary 219; 0.1 and 0.5 OD ranges). Cobalt concentrations were calculated by using  $\epsilon_{502}$  56.3 for  $\text{CoNO}_3^{2+}$  ( $1\ \text{mol}\ \text{dm}^{-3}$   $\text{NaCl}$ ) and  $\epsilon_{492}$  47.9 for  $\text{CoOH}_2^{3+}$  ( $2\ \text{mol}\ \text{dm}^{-3}$   $\text{HCl}$ ). Experiments were complete within 4 h and recoveries of cobalt exceeded 98%.

For the  $\text{NO}_3^-/\text{CF}_3\text{SO}_3^-$  experiments (constant ionic strength) the azido complex was dissolved in  $10\ \text{cm}^3$  of  $0.08\ \text{mol}\ \text{dm}^{-3}$   $\text{HClO}_4$ ,  $10\ \text{cm}^3$  of the appropriate mixture of  $2.0\ \text{mol}\ \text{dm}^{-3}$   $\text{NaNO}_3/0.016\ \text{mol}\ \text{dm}^{-3}$   $\text{HClO}_4$  and  $2.0\ \text{mol}\ \text{dm}^{-3}$   $\text{NaCF}_3\text{SO}_3/0.016\ \text{mol}\ \text{dm}^{-3}$   $\text{HClO}_4$  was added, and then the solution was treated as above.

For the experiments at varying ionic strength (no added  $\text{ClO}_4^-$ ,  $\text{CF}_3\text{SO}_3^-$ ) the complex in  $20\ \text{cm}^3$  of water or  $0.04\ \text{mol}\ \text{dm}^{-3}$   $\text{HNO}_3$  was mixed with the appropriate mixture of  $0.04\ \text{mol}\ \text{dm}^{-3}$   $\text{HNO}_3$  and  $2.0\ \text{mol}\ \text{dm}^{-3}$   $\text{NaNO}_3/0.04\ \text{mol}\ \text{dm}^{-3}$   $\text{HNO}_3$ , and the resultant mixture was treated as above.

It was very noticeable in these experiments that  $\text{ClO}_4^-$  and  $\text{NO}_3^-$  accelerated the rate of reaction and also that in the absence of  $\text{ClO}_4^-$  or  $\text{CF}_3\text{SO}_3^-$  (i.e.,  $\text{NO}_3^-$  only present) markedly more  $\text{CoNO}_3^{2+}$  was formed at low  $\text{NO}_3^-$  concentrations. It was found that if  $[\text{Co}(\text{O}-\text{H}_2)](\text{ClO}_4)_3$  dissolved in  $0.04\ \text{mol}\ \text{dm}^{-3}$   $\text{HClO}_4$  was left in the presence of relatively high concentrations ( $0.2\ \text{mol}\ \text{dm}^{-3}$ ) of  $\text{NaNO}_2$  for an appreciable time (ca. 20 min), traces of a yellow  $2+$  ion, presumably

(14) Using the expression  $K_{ip} = 4/3\pi a^3 N_A \exp(z_+ z_- e^2 / 4\pi\epsilon_0\epsilon_a kT)$  with  $a = 430\ \text{pm}$  for  $\text{Co}(\text{NH}_3)_6^{3+}, \text{Cl}^-$  (cf. F. Basolo and R. G. Pearson, "Mechanisms of Inorganic Reactions", 2nd ed., 1967, p 36).

Figure 1. Plots of  $k_{\text{obsd}}$  vs.  $[Y^-]$  ( $Y^- = \text{NO}_3, \text{Cl}$ ) where  $[Y^-] + [\text{ClO}_4^-] = 1.0 \text{ mol dm}^{-3}$  (i.e., constant ionic strength):  $\times$ , Cl;  $\bullet$ ,  $\text{NO}_3$ .

$\text{CoONO}_2^{2+}/\text{CoNO}_2^{2+}$ , were visible on the ion-exchange column. For this reason the  $[\text{NO}_2^-]_{\text{T}}$  was kept to a minimum.

**Chloride Competition.** A solution of the azido complex ( $1.28 \times 10^{-2}$  or  $0.64 \times 10^{-2} \text{ mol dm}^{-3}$ ) was mixed in equal parts with  $1.60 \times 10^{-2} \text{ mol dm}^{-3} \text{ NaNO}_2$  and stored in the dark (solution A). Solution B consisted of appropriate mixtures of  $2.0 \text{ mol dm}^{-3} \text{ NaCl}$  ( $0.016 \text{ mol dm}^{-3} \text{ HClO}_4$ ) with  $2.0 \text{ mol dm}^{-3} \text{ NaClO}_4$  ( $0.016 \text{ mol dm}^{-3} \text{ HClO}_4$ ,  $I$  constant),  $2.0 \text{ mol dm}^{-3} \text{ NaCF}_3\text{SO}_3$  ( $0.016 \text{ mol dm}^{-3} \text{ HClO}_4$ ,  $I$  constant), or  $0.016 \text{ mol dm}^{-3} \text{ HClO}_4$  ( $I$  variable). A  $20\text{-cm}^3$  amount of each of solutions A and B was pipetted into separate  $50\text{-mL}$  beakers, and solution A was added rapidly to solution B with hand mixing. After reaction was complete, the solution was filtered through Celite, degassed at reduced pressure (water pump), and allowed to equilibrate to  $25.0 \text{ }^\circ\text{C}$  (water bath). The optical density was then recorded to four decimal places at  $550 \text{ nm}$  ( $5\text{-}$  and  $10\text{-cm}$  cells, slit  $1.5 \text{ mm}$ , Cary 219 digital readout) and compared with standard spectra. Standards used were  $[\text{Co}(\text{NH}_3)_5\text{OH}_2](\text{ClO}_4)_3$  ( $M_r$  460.46;  $\epsilon_{550}$  21.4 (NaCl), 20.8 ( $\text{NaClO}_4$ ), 20.5 ( $\text{H}_2\text{O}$ )) and  $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$  ( $M_r$  250.46;  $\epsilon_{550}$  46.4 (NaCl), 46.1 ( $\text{NaClO}_4$ ), 45.3 ( $\text{H}_2\text{O}$ )). Concentration of electrolyte (where specified) was  $1.0 \text{ mol dm}^{-3}$ .

Some experiments (constant  $I$ ) were also carried out by using the chromatographic separation method as described above for the nitrate runs. A mixture of  $2.0 \text{ mol dm}^{-3} \text{ NaCl}$   $0.04 \text{ mol dm}^{-3}$  in  $\text{HClO}_4$  was used in place of the nitrate solution.

**Nitrate/Chloride Competition (Constant  $I$ ,  $1.0 \text{ mol dm}^{-3}$ ).** The procedure was as above for the chloride runs using a  $0.64 \times 10^{-2} \text{ mol dm}^{-3}$  stock  $\text{CoN}_3^{2+}$  solution and  $2.0 \text{ mol dm}^{-3} \text{ NaNO}_3/0.016 \text{ mol dm}^{-3} \text{ HClO}_4$ ; otherwise, identical reagents were used. Optical densities ( $10\text{-cm}$  cell) were recorded at  $550$  and  $508 \text{ nm}$  (isosbestic point for  $\text{CoCl}^{2+}$  with  $\text{CoOH}_2^{3+}$ ).  $\epsilon$  values used were as follows. At  $550 \text{ nm}$ :  $\text{CoOH}_2^{3+}$ , 21.0;  $\text{CoCl}^{2+}$ , 46.2;  $\text{CoNO}_3^{2+}$ , 29.4. At  $508 \text{ nm}$ :  $\text{CoOH}_2^{3+}$ ,  $\text{CoCl}^{2+}$ , 45.0;  $\text{CoNO}_3^{2+}$ , 55.7. In all cases filtration through Celite and degassing were essential for reproducible data.

## Results

**Kinetics.** Rate data at  $25.0 \text{ }^\circ\text{C}$  for the reaction

in the presence of  $Y^- = \text{NO}_3^-, \text{Cl}^-$  for  $[Y^-] + [\text{ClO}_4^-] = 1.0 \text{ mol dm}^{-3}$  (i.e., at constant ionic strength) are given in Figure 1; those for  $[\text{ClO}_4^-] + [\text{CF}_3\text{SO}_3^-] = 1.0 \text{ mol dm}^{-3}$  (constant ionic strength) and for  $\text{CF}_3\text{SO}_3^-$  and  $\text{ClO}_4^-$  alone (variable ionic strength,  $I = 0.04\text{--}1.0 \text{ mol dm}^{-3}$ ) are given in Figure 2. The data at constant ionic strength support the previously reported rate law for  $[\text{NO}_3^-] + [\text{ClO}_4^-] = 1.0 \text{ mol dm}^{-3}$ <sup>2b</sup>

$$k_{\text{obsd}} = k_{\text{obsd}}^0 + k_{\text{obsd}}^y [Y^-] \quad (6)$$

with  $k_{\text{obsd}}^0 = 5.2 \times 10^{-2} \text{ s}^{-1}$  and  $k_{\text{obsd}}^{\text{NO}_3} = 2.9 \times 10^{-2} \text{ s}^{-1} \text{ mol}^{-1} \text{ dm}^3$ ,  $k_{\text{obsd}}^{\text{Cl}} = 2.65 \text{ s}^{-1} \text{ mol}^{-1} \text{ dm}^3$  under the conditions  $[\text{H}^+]_{\text{T}} = 8.0 \times 10^{-3}$ ,  $[\text{NO}_2^-]_{\text{T}} = 4.0 \times 10^{-3} \text{ mol dm}^{-3}$ . Note that  $\text{Cl}^-$  is 100 times more effective than is  $\text{NO}_3^-$ . Using  $K_a = 5 \times 10^{-4}$

Figure 2. Plots of  $k_{\text{obsd}}$  vs.  $[Y^-]$  ( $Y^- = \text{ClO}_4, \text{TFS}$ ):  $\bullet$ ,  $[\text{TFS}^-] + [\text{ClO}_4^-] = 1.0 \text{ mol dm}^{-3}$  (constant ionic strength);  $\circ$ ,  $\text{ClO}_4^-$  alone ( $I = 1.0 \text{ mol dm}^{-3}$ );  $+$ ,  $\text{TFS}^-$  alone ( $I = 0.1\text{--}1.0 \text{ mol dm}^{-3}$ ).

$\text{mol dm}^{-3}$  for dissociation of  $\text{HNO}_2$ <sup>18</sup> and fitting the data to the full rate law<sup>18</sup>

$$-d[\text{CoN}_3^{2+}]/dt = (k_0 + k_y [Y^-]) [\text{H}^+] [\text{HNO}_2] [\text{CoN}_3^{2+}] \quad (7)$$

give  $k_0 = 3.3 \times 10^3 \text{ s}^{-1} \text{ mol}^{-2} \text{ dm}^6$  and  $k_y = 1.83 \times 10^3 \text{ s}^{-1} \text{ mol}^{-3} \text{ dm}^9$  ( $\text{NO}_3$ ) and  $1.67 \times 10^5 \text{ s}^{-1} \text{ mol}^{-3} \text{ dm}^9$  ( $\text{Cl}$ ). These are to be compared with values of  $3.0 \times 10^3 \text{ s}^{-1} \text{ mol}^{-2} \text{ dm}^6$  ( $k_0$ ) and  $1.3 \times 10^3 \text{ s}^{-1} \text{ mol}^{-3} \text{ dm}^9$  ( $k_{\text{NO}_3}$ ) obtained by Jackson et al.<sup>2b</sup> at somewhat different  $\text{H}^+$  and  $\text{NO}_2^-$  concentrations. Clearly the full rate expression (7) is supported by all three studies, and we are in substantial agreement with Jackson's data for  $Y = \text{NO}_3^-$ . We did not observe the decrease in  $k_{\text{Cl}}$  with increasing  $[\text{Cl}^-]$  found by Haim and Taube.<sup>18</sup>

The data in Figure 2 show that with a change to  $\text{CF}_3\text{SO}_3^-$  as supporting electrolyte and variation of  $[\text{ClO}_4^-]$  the latter anion also accelerates the reaction, albeit to a lesser extent than  $\text{Cl}^-$  or  $\text{NO}_3^-$ . The  $[\text{ClO}_4^-] + [\text{CF}_3\text{SO}_3^-] = 1.0 \text{ mol dm}^{-3}$  data given a linear plot of  $k_{\text{obsd}}$  vs.  $[\text{ClO}_4^-]$  in agreement with eq 6. For  $\text{CF}_3\text{SO}_3^-$  alone (i.e.,  $I$  variable,  $0.04\text{--}1.0 \text{ mol dm}^{-3}$ ) little change in rate occurs above  $0.2 \text{ mol dm}^{-3}$ , suggesting that ionic strength effects do not have a large influence on the rate. This is supported by the data for  $\text{ClO}_4^-$  alone ( $I$  variable), which are in substantial agreement with those at constant ionic strength,  $[\text{ClO}_4^-] + [\text{CF}_3\text{SO}_3^-] = 1.0 \text{ mol dm}^{-3}$ . Some allowance must be made in these comparisons for the undoubted increase in ionic activities at the lowest ionic strengths,  $I < 0.1 \text{ mol dm}^{-3}$ . Our value at  $[\text{ClO}_4^-] = 0.5 \text{ mol dm}^{-3}$ ,  $k_{\text{obsd}} = 2.87 \times 10^{-2} \text{ s}^{-1}$ , is in agreement with a value of  $2.56 \times 10^{-2} \text{ s}^{-1}$  calculated for the same conditions (cf. Table I) by using the results of Haim and Taube<sup>18</sup> at somewhat different  $\text{H}^+$  and  $\text{NO}_2^-$  concentrations. It is clear from these data that ionic effects are not of major importance and that  $\text{CF}_3\text{SO}_3^-$  is the more appropriate reference electrolyte.

With  $\text{CF}_3\text{SO}_3^-$  as reference the revised  $k_{\text{obsd}}^0$  and  $k_{\text{obsd}}^y$  values, eq 6, are  $1.05 \times 10^{-2} \text{ s}^{-1}$  and  $2.69$  ( $\text{Cl}$ ),  $7.1 \times 10^{-2}$  ( $\text{NO}_3$ ),  $3.5 \times 10^{-2}$  ( $\text{ClO}_4$ )  $\text{s}^{-1} \text{ mol}^{-1} \text{ dm}^3$ , respectively. With use of the full rate expression, eq 7, the values become  $k_0 = 6.6 \times 10^2 \text{ s}^{-1} \text{ mol}^{-2} \text{ dm}^6$  and  $k_y = 1.70 \times 10^5$  ( $\text{Cl}$ ),  $4.48 \times 10^3$  ( $\text{NO}_3$ ), and  $2.21 \times 10^3$  ( $\text{ClO}_4$ )  $\text{s}^{-1} \text{ mol}^{-3} \text{ dm}^9$ , respectively.

**Competition Data.** Table II gives data for  $\text{NO}_3^-$  at constant ionic strength,  $1.0 \text{ mol dm}^{-3}$ . The  $\text{CoNO}_3^{2+}$  and  $\text{CoOH}_2^{3+}$  products were separated by ion-exchange chromatography at

<sup>a</sup> Average of two or three measurements. <sup>b</sup>  $10^2 F_{\text{obsd}} = \% \text{CoCl}^{2+}$ ;  $10^2(1 - F_{\text{obsd}}) = \% \text{CoOH}_2^{3+}$ . <sup>c</sup>  $R = [\text{CoCl}^{2+}]/[\text{CoOH}_2^{3+}][\text{Cl}^-]$ .

$5^\circ\text{C}$  and were estimated spectrophotometrically (cf. Experimental Section). Only limited data were obtained for  $[\text{NO}_3^-] + [\text{ClO}_4^-] = 1.0 \text{ mol dm}^{-3}$  (Table IIA) since Jackson et al. have reported more extensive data.<sup>2b</sup> Our  $[\text{H}^+]$  condition is similar to theirs, but competition is somewhat higher (32% vs. 28% in  $1.0 \text{ mol dm}^{-3} \text{NO}_3^-$ ). We believe this discrepancy arises from the different experimental procedures, ours being similar to that used in an earlier study.<sup>6</sup> The one experiment in  $1.0 \text{ mol dm}^{-3} \text{HNO}_3$ , 33.0%  $\text{CoNO}_3^{2+}$ , agrees well with that found previously, 33.2%,<sup>6</sup> and with the results at the lower  $[\text{H}^+]$ . Thus the amount of  $\text{CoNO}_3^{2+}$  appears to be  $[\text{H}^+]$  independent. Also the presence of  $\text{Hg}^{2+}$  ( $0.05 \text{ mol dm}^{-3}$ ) did not affect  $\text{CoNO}_3^{2+}$  production, although our single result, 32.1%, differs appreciably from that obtained by Reynolds and Alton, 38%.<sup>2a</sup> Our "R values" ( $[\text{CoNO}_3^{2+}]/[\text{CoOH}_2^{3+}][\text{NO}_3^-]$ ) are somewhat variable but do suggest a higher value in  $0.1 \text{ mol dm}^{-3} \text{NO}_3^-$  compared to  $1.0 \text{ mol dm}^{-3} \text{NO}_3^-$ . Jackson's more consistent values<sup>2b</sup> showed the same trend, although these were held to be constant over the entire range.

Table IIB lists data for  $[\text{NO}_3^-] + [\text{CF}_3\text{SO}_3^-] = 1.0 \text{ mol dm}^{-3}$ , and a more certain decrease in  $R_{\text{NO}_3}$  with increasing  $[\text{NO}_3^-]$  is now apparent. While each value is not sufficiently accurate to discount overall constancy (we estimate a reliability of  $\pm 0.5\%$  in  $10^2 F_o$  by the ion-exchange method), the decrease is regular and larger than in Table IIA.

Table III gives competition data for  $\text{Cl}^-$  at constant ionic strength,  $1.0 \text{ mol dm}^{-3}$  ( $\text{ClO}_4^-$ ,  $\text{CF}_3\text{SO}_3^-$  added). Here the larger difference in extinction between  $\text{CoOH}_2^{3+}$  and  $\text{CoCl}^{2+}$

<sup>a</sup>  $10^2 F_{\text{Cl}} = \% \text{CoCl}^{2+}$ . <sup>b</sup>  $10^2 F_{\text{NO}_3} = \% \text{CoNO}_3^{2+}$ . <sup>c</sup>  $R_{\text{Cl}} = [\text{CoCl}^{2+}]/([\text{CoOH}_2^{3+}][\text{Cl}^-])$ . <sup>d</sup>  $R_{\text{NO}_3} = [\text{CoNO}_3^{2+}]/([\text{CoOH}_2^{3+}][\text{NO}_3^-])$ .

**Figure 3.**  $P_{\text{obs}}$  vs.  $[\text{NO}_3^-]$  (●) and  $[\text{Cl}^-]$  (○), for the competition of nitrate and chloride at varying ionic strength. Note the significantly larger  $P$  values at the low  $[\text{NO}_3^-]$  and  $[\text{Cl}^-]$  compared to those in Tables II-IV.

at  $550 \text{ nm}$  allowed the direct spectroscopic method to be used. Experiments were done in duplicate, and agreement in  $10^2 F_o$  was better than 0.1%. The data in the presence of  $\text{ClO}_4^-$  show a regular increase in  $R_{\text{Cl}}$  with increasing  $[\text{Cl}^-]$  while those in the presence of  $\text{CF}_3\text{SO}_3^-$  show a regular decrease in  $R_{\text{Cl}}$ .

Table IV gives  $R_{\text{NO}_3}$  and  $R_{\text{Cl}}$  data for  $[\text{NO}_3^-] + [\text{Cl}^-] = 1.0 \text{ mol dm}^{-3}$  obtained by direct spectroscopic measurements at 508 and 550 nm. The former wavelength is an isobestic point for  $\text{CoOH}_2^{3+}$  and  $\text{CoCl}^{2+}$  and hence gives  $\text{CoNO}_3^{2+}$  directly. At 550 nm the larger change in extinction results from contributions from both  $\text{CoCl}^{2+}$  and  $\text{CoNO}_3^{2+}$  although the former contribution predominates. Experiments were done in duplicate, and the average is reported. Both  $R_{\text{NO}_3}$  and  $R_{\text{Cl}}$  show regular variations with the former decreasing with increasing  $[\text{NO}_3^-]$  and the latter increasing with increasing  $[\text{Cl}^-]$ .

Extensive data were collected for  $\text{NO}_3^-$  and  $\text{Cl}^-$  competition in the absence of supporting electrolyte (i.e., variable ionic strength). Figure 3 summarizes these as plots of  $P_{\text{obsd}} = [\text{CoY}^{2+}]/[\text{CoOH}_2^{3+}]$  vs.  $[\text{Y}^-]$  for  $\text{Y}^- = \text{NO}_3^-$  and  $\text{Cl}^-$ .  $\text{CoNO}_3^{2+}$  was again measured by the ion-exchange method and  $\text{CoCl}^{2+}$  by direct spectroscopic analysis at 550 nm. In comparison to the data at constant ionic strength, more  $\text{CoNO}_3^{2+}$  and  $\text{CoCl}^{2+}$  are formed under all conditions but especially at low  $[\text{Y}^-]$  (more than double the amount at  $[\text{Y}^-] = 0.1 \text{ mol dm}^{-3}$ ). A similar result was found in the study with  $t\text{-}[\text{Co}(\text{tren})(\text{NH}_3)\text{N}_3]^{2+}$ .<sup>10</sup>

## Discussion

**Kinetics.** Two new features appear here. First, at constant ionic strength ( $1.0 \text{ mol dm}^{-3}$ )  $\text{ClO}_4^-$  accelerates the reaction in addition to  $\text{NO}_3^-$  and  $\text{Cl}^-$ , albeit to a lesser extent. The rates for all three anions show a linear dependence on concentration, at least up to  $1.0 \text{ mol dm}^{-3}$ , and the contribution of the an-

Table V. Kinetic Data

Y	$(k_1'/k_2')/$ $\text{mol}^{-2} \text{dm}^6$	$k_1'/\text{mol}^{-2}$ $\text{dm}^6 \text{s}^{-1}$	$k_2'/\text{s}^{-1}$	$k_y/\text{mol}^{-3}$ $\text{dm}^9 \text{s}^{-1}$	$k_y' =$ $k_y(k_2'/k_1')/$ $\text{mol}^{-1} \text{dm}^3 \text{s}^{-1}$	$(k_y'/k_2')/$ $\text{mol}^{-1} \text{dm}^3$	$(k_y'/k_2') \cdot$ $[\text{CoN}_3^{2+}]^h$

<sup>a</sup> Calculated from  $K = [\text{HNO}_2] a_{\text{HCl}}/[\text{NOCl}] a_{\text{H}_2\text{O}} = 0.88 \times 10^3 \text{ mol kg}^{-1}$  measured at 25 °C,  $4 < I < 6 \text{ mol dm}^{-3}$ ,<sup>19</sup> by using  $\gamma_{\text{HCl}} = 0.752^{37a}$  and  $a_{\text{H}_2\text{O}} = 0.967^{37b}$  for  $I = 1.0 \text{ mol dm}^{-3}$  solutions and by assuming  $a_{\text{HCl}}/\text{mol kg}^{-1} \approx a_{\text{HCl}}/\text{mol dm}^{-3}$ . <sup>b</sup> Calculated from  $K = [\text{HNO}_2] a_{\text{HBr}}/[\text{NOBr}] a_{\text{H}_2\text{O}} = 19.6 \text{ mol kg}^{-1}$  (25 °C)<sup>38</sup> by using  $a_{\text{H}_2\text{O}} = 0.967^{37b}$  and  $\gamma_{\text{Br}} = 0.798$  calculated from  $\log \gamma_{\text{Br}} = \log \gamma_{\text{Br}(o)} - \alpha_{\text{B}} M_c^{37c}$  with  $\gamma_{\text{Br}(o)} = 0.871$ ,<sup>37d</sup>  $\alpha_{\text{B}} = 0.038$ ,<sup>37e</sup> and  $M_c = 1.0 \text{ mol kg}^{-1}$ . <sup>c</sup> 0 °C,  $I = 0.06$ . The numerical values of these rates depend on the values for the dissociation constants of hydrazoic and nitrous acids, which are subject to considerable possible error.<sup>33</sup> <sup>d</sup> Calculated from  $k_2' = k_1'/(k_1'/k_2')$ . <sup>e</sup> 25 °C,  $I = 1.0 \text{ mol dm}^{-3}$  (our results). <sup>f</sup> 25 °C,  $I = 0 \text{ mol dm}^{-3}$  (calculation is based on a thermodynamic cycle<sup>36</sup>). <sup>g</sup> 0 °C,  $I = 1.0 \text{ mol dm}^{-3}$ .<sup>35</sup> <sup>h</sup> Calculated for  $[\text{CoN}_3^{2+}] = 4 \times 10^{-4} \text{ mol dm}^{-3}$ ; cf. Table I.

ion-independent part  $k_{\text{obsd}}^0$  is small. Thus in  $1.0 \text{ mol dm}^{-3}$  Y<sup>-</sup>  $k_{\text{obsd}}^0$  contributes only 0.4% (Cl<sup>-</sup>), 13% (NO<sub>3</sub><sup>-</sup>), and 23% (ClO<sub>4</sub><sup>-</sup>). For the mixed-electrolyte media ( $[\text{Y}^-] + [\text{ClO}_4^-] = 1.0 \text{ mol dm}^{-3}$ ) both anion-dependent paths make a contribution (eq 8), with  $k_{\text{obsd}}^0$  never exceeding 23% of  $k_{\text{obsd}}$  under any con-

$$k_{\text{obsd}} = k_{\text{obsd}}^0 + k_{\text{obsd}}^y[\text{Y}^-] + k_{\text{obsd}}^{\text{ClO}_4}[\text{ClO}_4^-] \quad (8)$$

dition. This additional contribution complicates any analysis of the products based on the rate expression, and corrections to previous correlations are necessary (Tables I and II of ref 2b).

The second new feature is the apparent insensitivity in the rate to changes in ionic strength. This comes from a consideration of the CF<sub>3</sub>SO<sub>3</sub><sup>-</sup> data (Figure 2). Little change in  $k_{\text{obsd}}$  occurs over the range  $I = 0.2$ – $1.0 \text{ mol dm}^{-3}$ . Some variation is found below  $0.2 \text{ mol dm}^{-3}$ , but this probably results from gross changes in the activity of the ionic species in this region. Also, above  $0.2 \text{ mol dm}^{-3}$   $k_{\text{obsd}}$  for ClO<sub>4</sub><sup>-</sup> alone (variable ionic strength) is similar to that for ClO<sub>4</sub><sup>-</sup> at constant ionic strength ( $[\text{ClO}_4^-] + [\text{CF}_3\text{SO}_3^-] = 1.0 \text{ mol dm}^{-3}$ ). The two results imply that above  $0.2 \text{ mol dm}^{-3}$  activity effects either cancel or are unimportant and that in this region ionic strength effects as such have little influence on the rate.

- (19) H. Schmid and A. Maschka, *Z. Phys. Chem., Abt. B*, **49**, 171 (1941). Cf. "Mellor's Comprehensive Treatise on Inorganic and Theoretical Chemistry", Vol. VIII, Supplement II, Section XXXII, p 354.
- (20) In  $0.1 \text{ mol dm}^{-3}$  Cl<sup>-</sup> the various contributions to  $k_{\text{obsd}}$  (eq 8), at  $I = 1.0 \text{ mol dm}^{-3}$  (ClO<sub>4</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>, CF<sub>3</sub>SO<sub>3</sub><sup>-</sup>), are  $k_0'$  3.4%,  $k_{\text{ClO}_4}$  10.2%,  $k_{\text{Cl}}$  86.5%;  $k_0'$  3.0%,  $k_{\text{NO}_3}$  18.6%,  $k_{\text{Cl}}$  78.4%; and  $k_0'$  3.6%,  $k_{\text{CF}_3\text{SO}_3}$  4.3%,  $k_{\text{Cl}}$  92.1%.
- (21) Our data are not sufficiently accurate to compare the products resulting from the individual  $k_0'$ ,  $k_{\text{ClO}_4}[\text{ClO}_4^-]$ , and  $k_{\text{NO}_3}[\text{NO}_3^-]$  paths (where the attacking agents are NO<sup>+</sup>(aq), NOClO<sub>4</sub>, and NONO<sub>3</sub>, respectively). All we can be sure of at this time is that ClO<sub>4</sub><sup>-</sup> and NO<sub>3</sub><sup>-</sup> from the NOY species do not enter. For the very different leaving group HgCl<sup>+</sup> there is some evidence of a memory effect,<sup>10</sup> but it has yet to be established whether the entering anion comes via interchange within CoCl, HgY<sup>3+</sup> or from another source.

This second feature is unusual and suggests that one of the reactants is uncharged. A good candidate is YNO, reaction 9. A rate law consistent with that observed may then be derived.

Steady-state treatment ( $[\text{NO}^+(\text{aq})]$ ,  $[\text{YNO}(\text{aq})]$  small and hence  $[\text{HNO}_2] \approx [\text{HNO}_2]_{\text{T}}$ ) gives eq 11. When  $(k_0'/k_4')$ -

$$\frac{-d[\text{CoN}_3^{2+}]}{dt} = \left\{ \frac{k_0'(k_3'/k_4')}{1 + (k_0'/k_4')[\text{CoN}_3^{2+}]} + \frac{k_y'(k_1'/k_2')}{1 + (k_y'/k_2')[\text{CoN}_3^{2+}]} \right\} [\text{Y}^-][\text{H}^+][\text{HNO}_2][\text{CoN}_3^{2+}] \quad (11)$$

$[\text{CoN}_3^{2+}]$ ,  $(k_y'/k_2')[\text{CoN}_3^{2+}] \ll 1$ , this expression reduces to eq 12. Comparison with the observed rate law yields  $k_0$

$$\frac{-d[\text{CoN}_3^{2+}]}{dt} = \{k_0'(k_3'/k_4') + k_y'(k_1'/k_2')\} [\text{Y}^-][\text{H}^+][\text{HNO}_2][\text{CoN}_3^{2+}] \quad (12)$$

$= k_0'(k_3'/k_4')$  and  $k_y = k_y'(k_1'/k_2')$ . Rate data for reactions 9a and 10a from the literature combined with our values for  $k_0$  and  $k_y$  (cf. Table V) validate the assumptions used in deriving eq 12 from eq 11.

For Y<sup>-</sup> = Br<sup>-</sup>,  $k_y'/k_2' \approx 680 \text{ mol}^{-1} \text{ dm}^3$  (Table V), suggesting that deviations from first-order behavior are to be expected when  $[\text{CoN}_3^{2+}]$  exceeds  $2 \times 10^{-3} \text{ mol dm}^{-3}$ . However, at the highest concentrations accessible to us using stopped-flow methods ( $[\text{CoN}_3^{2+}] = 2 \times 10^{-3} \text{ mol dm}^{-3}$ ,  $[\text{Br}^-] = 0.1 \text{ mol dm}^{-3}$ ),<sup>31</sup> no deviations from first-order behavior were observed during the first half-life ( $t_{1/2} = 21.5 \text{ ms}$ ). However for the Br<sup>-</sup>-catalyzed nitrosation of *o*-chloroaniline<sup>32</sup> and the

(31) An experiment was performed with  $[\text{NO}_2^-]_{\text{T}} = 2 \times 10^{-2} \text{ mol dm}^{-3}$ ,  $[\text{H}^+]_{\text{T}} = 4 \times 10^{-2} \text{ mol dm}^{-3}$ ,  $[\text{CoN}_3^{2+}]_{\text{init}} = 2 \times 10^{-3} \text{ mol dm}^{-3}$ ,  $[\text{ClO}_4^-] = 0.8 \text{ mol dm}^{-3}$ , and  $[\text{Br}^-] = 0.2 \text{ mol dm}^{-3}$  for which  $k_{\text{obsd}} = 32 \text{ s}^{-1}$  and hence  $k_{\text{Br}} = 7.8 \times 10^5 \text{ mol}^{-3} \text{ dm}^9 \text{ s}^{-1}$  (cf. Taube's value of  $3.3 \times 10^5 \text{ mol}^{-3} \text{ dm}^9 \text{ s}^{-1}$ ,  $I = 0.5 \text{ mol dm}^{-3}$ ). Solutions were degassed, and a good infinity reading was obtained before the onset of bubble formation.

**Figure 4.** Plots of  $P$  vs.  $[Y^-]$  for products (Tables II–IV) at constant ionic strength,  $I = 1.0 \text{ mol dm}^{-3}$ :  $\text{NO}_3^- + \text{CF}_3\text{SO}_3^-$  (●),  $\text{NO}_3^- + \text{Cl}^-$  (○),  $\text{NO}_3^- + \text{ClO}_4^-$  (+);  $\text{Cl}^- + \text{CF}_3\text{SO}_3^-$  (●),  $\text{Cl}^- + \text{NO}_3^-$  (○),  $\text{Cl}^- + \text{ClO}_4^-$  (+).

$\text{Cl}^-$ -catalyzed nitrosation of  $\text{N}_3^-$ ,<sup>33</sup> the rate does become independent of substrate concentration (cf. eq 11) and this justifies the intermediacy of a  $\text{YNO}(\text{aq})$  species ( $k_1'$  becomes rate determining) in all these processes.

Table V gives  $k_y'$  and  $k_0'$  values calculated by using literature data for  $k_1'/k_2'$  and  $k_3'/k_4'$ . The values  $k_y'(\text{Cl}) = 1.9 \times 10^8$ ,  $k_y'(\text{Br}) = 3.5 \times 10^7$ , and  $k_0' = 3.3 \times 10^9 \text{ mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$  are large and approach the diffusion-controlled limit ( $k_{\text{diff}} \approx 7 \times 10^9 \text{ mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$ ). A similar situation occurs in the nitrosation of organic amines by nitrosyl halides where  $k_y'(\text{Br})$  approaches  $k_y'(\text{Cl})$  and  $k_{\text{diff}}$  as the basicity of the amine increases.<sup>34</sup> On this basis we would anticipate similar rates for other  $\text{CoN}_3^{2+}$  substrates and low activation energies ( $E_a \approx 20 \text{ kJ mol}^{-1}$  for a diffusion-controlled reaction). Both findings would be unusual for substitution at a  $\text{Co}(\text{III})$  center.

**Products.** Two results make it clear that incorporation of  $Y^-$  into the products, as  $\text{CoY}^{2+}$ , is not controlled by the reactant  $\text{YNO}$ , i.e., by species that appear in the rate expression; incorporation must occur by another process. The first is the regular increase in  $\text{CoY}^+$  production under conditions where the rate is completely or largely controlled by the  $k_y'[Y^-]$  term. Figure 4 plots the results of Tables II–IV in terms of  $P_{\text{obsd}} (= [\text{CoY}^{2+}]/[\text{CoOH}_2^{3+}])$  vs.  $[Y^-]$  for the data at constant ionic strength,  $I = 1.0 \text{ mol dm}^{-3}$ . For  $Y = \text{Cl}^-$  the products are controlled by  $k_{\text{Cl}}'[\text{Cl}^-]$  ( $\geq 86\%$  of  $k_{\text{obsd}}$  at  $[\text{Cl}^-] \geq 0.1 \text{ mol dm}^{-3}$ ),<sup>20</sup> yet a steady increase in  $\text{CoCl}^{2+}$  production continues up to  $1.0 \text{ mol dm}^{-3} \text{ Cl}^-$ . A close to constant product ratio with increasing  $\text{Cl}^-$  would result if  $\text{CoCl}^{2+}$  came directly from interchange within the  $\text{CoN}_3\text{ONCl}^{2+}$  species. A similar result occurs for entry of  $\text{NO}_3^-$  in the presence of  $\text{ClO}_4^-$ ,  $\text{CF}_3\text{SO}_3^-$ , and  $\text{Cl}^-$  (Figure 4) although here the  $k_{\text{ClO}_4}[\text{ClO}_4^-]$  and  $k_{\text{Cl}}[\text{Cl}^-]$  contributions are more significant.<sup>20</sup> Similarly for the  $[\text{NO}_3^-] + [\text{Cl}^-] = 1.0 \text{ mol dm}^{-3}$  data the rate is controlled to an overwhelming extent (89% at  $0.2 \text{ mol dm}^{-3} \text{ Cl}^-$ ) by the  $k_{\text{Cl}}[\text{Cl}^-]$  term in the rate law, yet significant  $\text{CoNO}_3^{2+}$  production occurs up to  $1.0 \text{ mol dm}^{-3} \text{ Cl}^-$ . (These data effectively eliminate Schemes II and III of Jackson et al.<sup>2b</sup>) Clearly  $P_{\text{obsd}}$  is controlled by the  $\text{YNO}$  term in the rate, i.e., by  $k_y'$ , but anion entry does not occur via the  $\text{YNO}(\text{aq})$  species but by some other process. This could be subsequent to the

**Figure 5.** Plots of  $R^{-1} (= [\text{CoOH}_2^{3+}][Y^-]/[\text{CoY}^{2+}])$  vs.  $[Y^-]$  for products at constant ionic strength,  $I = 1.0 \text{ mol dm}^{-3}$ :  $\text{NO}_3^- + \text{CF}_3\text{SO}_3^-$  (●),  $\text{NO}_3^- + \text{Cl}^-$  (○),  $\text{NO}_3^- + \text{ClO}_4^-$  (+);  $\text{Cl}^- + \text{CF}_3\text{SO}_3^-$  (●),  $\text{Cl}^- + \text{NO}_3^-$  (○),  $\text{Cl}^- + \text{ClO}_4^-$  (+).

rate-determining step as suggested by Jackson<sup>2b</sup> or could occur via a  $Y^-$  species which is present in the activated complex but which does not make its presence felt in the experiment rate law.

Careful scrutiny of Figure 4 leads to a further observation. This is most apparent for  $\text{CoCl}^{2+}$  production in the presence of  $\text{NO}_3^-$ ,  $\text{ClO}_4^-$ , and  $\text{CF}_3\text{SO}_3^-$  but also holds for  $\text{CoNO}_3^{2+}$  in the presence of  $\text{Cl}^-$ ,  $\text{ClO}_4^-$ , and  $\text{CF}_3\text{SO}_3^-$ . In each case a nonlinear relationship between  $P_{\text{obsd}}$  and  $[Y^-]$  occurs, which for  $[\text{Cl}^-] + [\text{NO}_3^-] = 1.0 \text{ mol dm}^{-3}$  is concave and for  $[\text{Cl}^-] + [\text{CF}_3\text{SO}_3^-] = 1.0 \text{ mol dm}^{-3}$  is convex. For  $[\text{Cl}^-] + [\text{ClO}_4^-] = 1.0 \text{ mol dm}^{-3}$  the plot appears to be linear, but careful examination shows that it also is concave. This curvature at constant ionic strength is excellent evidence for some sort of associative behavior between  $Y^-$  and the product-determining species. The shape suggests competitive association, with the order  $\text{NO}_3^- > \text{ClO}_4^- > \text{Cl}^- > \text{CF}_3\text{SO}_3^-$ . This analysis is substantiated by plots of  $R^{-1}$  vs.  $[\text{Cl}^-]$  (Figure 5) ( $R = P/[\text{Cl}^-]$ ), where the linear correlations have positive, negative, and slightly negative slopes for  $\text{CF}_3\text{SO}_3^-$ ,  $\text{NO}_3^-$ , and  $\text{ClO}_4^-$ , respectively. These latter plots also suggest that the products are controlled by a single equilibrium process rather than by a combination of isolated events such as might result from direct injection together with entry from the ion pair.<sup>21</sup>

For the  $\text{CoNO}_3^{2+}$  data at constant ionic strength (Tables II and IV) these trends are not as obvious, but curvature in the  $P_{\text{obsd}}$  vs.  $[\text{NO}_3^-]$  data (Figure 4) becomes apparent in the  $R^{-1}$  vs.  $[\text{NO}_3^-]$  plots of Figure 5. The increasingly positive slopes for  $\text{ClO}_4^-$ ,  $\text{CF}_3\text{SO}_3^-$ , and  $\text{Cl}^-$  correspond to an increasing ability by  $\text{NO}_3^-$  to compete for entry. It is tempting to relate this to a larger ion-pair constant for  $\text{NO}_3^-$  relative to the other anions, but this is not a requirement of the mechanism as we shall see below. The results for  $\text{CoCl}^{2+}$  and  $\text{CoNO}_3^{2+}$  for  $[\text{Cl}^-] + [\text{NO}_3^-] = 1.0 \text{ mol dm}^{-3}$  are complementary with increased  $\text{NO}_3^-$  entry being accompanied by a decrease in  $\text{CoCl}^{2+}$  production. This also supports competitive association with  $\text{NO}_3^-$  being somewhat more effective than  $\text{Cl}^-$ .

A similar analysis can be made for the extensive  $\text{CoNO}_3^{2+}$  and  $\text{CoCl}^{2+}$  data in the absence of a supporting electrolyte (Figure 3). Here curvature in the  $P_{\text{obsd}}$  vs.  $[Y^-]$  plots is very pronounced, and clearly constancy in  $R$  cannot obtain. However a new variable now enters, the possibility of changing activities in the product-determining species due to changes in ionic strength. However the  $R^{-1}$  vs.  $[Y^-]$  plots are linear above  $I \approx 0.4 \text{ mol dm}^{-3}$  (Figure 6), with the steeper slopes (compared to Figure 5) in agreement with the absence of a competing anion. The linear part also suggests that variations in the activity coefficients for the product-determining species

Figure 6. Plots of  $R^{-1}$  ( $=[\text{CoOH}_2^{3+}][\text{Y}^-]/[\text{CoY}^{2+}]$ ) vs.  $[\text{Y}^-]$  for products at variable ionic strength,  $I = 0\text{--}2.0$  mol  $\text{dm}^{-3}$ :  $\text{NO}_3^-$  data,  $\bullet$ ;  $\text{Cl}^-$  data,  $\circ$ .

are unimportant in this region. Below  $I \approx 0.4$  mol  $\text{dm}^{-3}$  the increased slopes are predictable in terms of sharply increasing activity coefficients for  $\text{Y}^-$  and the cobalt complex.

Significant advances have been made in recent years in determining activity coefficients for ionic species at concentrations above those covered by the Debye-Hückel limiting law. According to Pitzer<sup>22</sup> the theoretical framework is now available to accurately represent the effects of short-range forces to concentrations in excess of 1 mol  $\text{dm}^{-3}$ , and a semiempirical expression<sup>23</sup> is available to fit experimental data for both pure- and mixed-electrolyte systems, including cobalt(III) complexes, to surprisingly high ionic strengths,  $I > 3$  mol  $\text{dm}^{-3}$ . For the present system we have

with

$$K^c = K^T \left( \frac{\gamma_{\pm,21} + \gamma_{\pm,1}}{\gamma_{\pm,11}} \right) = K^T \frac{(\gamma_{\pm,21})^3}{(\gamma_{\pm,11})^2} \quad (13)$$

where the  $\gamma_{\pm}$ 's represent the mean ionic activity coefficients for the completely dissociated  $\text{CoN}_3^{2+}$  ( $\gamma_{\pm,21}$ ) and  $\text{Y}^-\text{CoN}_3^{2+}$  ( $\gamma_{\pm,11}$ ) species. Masterton has tabulated (from osmotic measurements)  $\gamma_{\pm}$  data for various  $[\text{Co}(\text{NH}_3)_5\text{X}]^{2+}$  (i.e., 2:1) ions<sup>24</sup> and for  $[\text{Co}(\text{en})_2(\text{NCS})\text{Cl}]^+$  (i.e., 1:1),<sup>25</sup> to concentrations in excess of 1 mol  $\text{dm}^{-3}$ , but the difficulty still remains to relate these experimental values to those for the completely dissociated ions necessary to evaluate  $K^c$ . However Masterton's  $K^T$  values (10–20 mol<sup>-1</sup>  $\text{dm}^3$ ) for various  $[\text{Co}(\text{NH}_3)_5\text{X}]_2$  salts are somewhat larger than those found for "simple" salts of the same charge type, and their order,  $\text{Y}^- = \text{Cl}^- < \text{Br}^- < \text{I}^- < \text{NO}_3^-$ , is the reverse of that expected for a strictly Coulombic-type association. For our purpose it is significant that  $\text{NO}_3^-$  appears to form the strongest ion pair of those salts studied by Masterton and  $\text{Cl}^-$  one of the weakest. It is apparent from these observations that appreciable amounts of  $\text{CoN}_3^{2+}$  will be ion paired under our conditions.

**Mechanism for Product Formation.** On the basis of the above analysis the following mechanism is proposed for incorporation of anions  $\text{Y}^-$  into the products. The product-determining species is represented at the ion-paired substrate  $\text{CoN}_3^{2+}\text{Y}^-$  in association with  $\text{YNO}(\text{aq})$ , but it must be emphasized that the two  $\text{Y}^-$  entities are clearly distinguished. The choice of  $\text{CoN}_3^{2+}\text{Y}^-$  as one reactant is not at variance with the experimental rate law (cf. Introduction) and is forced upon us by the deduction that the slowest step in the overall reaction is the very rapid (close to the diffusion limit) association of  $\text{YNO}(\text{aq})$  with the cobalt(III) reactant and by the observation that the incorporated  $\text{Y}^-$  group is not that present in the associated  $\text{YNO}$  species. Thus the incorporation of  $\text{Y}^-$  must

### Scheme II

occur at a rate in excess of  $10^8\text{--}10^9$  mol  $\text{dm}^{-3}$   $\text{s}^{-1}$ , and this limits the lifetime of any subsequent intermediate including  $\text{CoN}_3^{2+}\text{NOY}$  and elusive 5-coordinate  $\text{Co}^{3+}$  species. We believe the preformed ion pair provides a more attractive route to the incorporation of  $\text{Y}^-$  than pathways involving  $\text{Y}^-$  and short-lived intermediates. Our proposal is in effect the "preassociation" possibility proposed by Ridd for nitrosation reactions<sup>34</sup> and recently discussed more generally by Jencks.<sup>39</sup>

Scheme II depicts our proposal for the system  $[\text{NO}_3^-] + [\text{Cl}^-] = 1.0$  mol  $\text{dm}^{-3}$  under conditions where the  $k_{\text{obsd}}^{\text{Cl}}$  term dominates the rate. The  $k_w$ ,  $k_w''$ ,  $k_w'''$ ,  $k_{\text{NO}_3}'''$ , and  $k_{\text{Cl}}''$  parameters represent rate constants for entry of water or anion subsequent to the rate-determining steps represented by  $k^*_{\text{Cl}}$ ,  $k^*_{\text{NO}_3}$ , and  $k^*_{\text{NO}_3}$ .

$$\text{When } k^*_{\text{Cl}} = k^*_0 = k^*_{\text{NO}_3}$$

$$R_{\text{NO}_3} = \frac{[\text{CoN}_3^{2+}]}{[\text{CoOH}_2^{3+}][\text{NO}_3^-]} = \frac{k_{\text{NO}_3}''' K^c_{\text{NO}_3}}{k_w + k_w''' K^c_{\text{NO}_3} [\text{NO}_3^-] + k_w'' K^c_{\text{Cl}} [\text{Cl}^-]}$$

$$\frac{1}{R_{\text{NO}_3}} = \frac{k_w}{k_{\text{NO}_3}''' K^c_{\text{NO}_3}} + \frac{k_w'''}{k_{\text{NO}_3}'''} [\text{NO}_3^-] + \frac{k_w'' K^c_{\text{Cl}}}{k_{\text{NO}_3}''' K^c_{\text{NO}_3}} [\text{Cl}^-]$$

Since  $[\text{Cl}^-] = 1.0 - [\text{NO}_3^-]$

$$\frac{1}{R_{\text{NO}_3}} = \frac{k_w + k_w'' K^c_{\text{Cl}}}{k_{\text{NO}_3}''' K^c_{\text{NO}_3}} + \frac{k_w'' K^c_{\text{NO}_3} - k_w'' K^c_{\text{Cl}}}{k_{\text{NO}_3}''' K^c_{\text{NO}_3}} [\text{NO}_3^-] \quad (14)$$

Similarly

$$\frac{1}{R_{\text{Cl}}} = \frac{k_w + k_w''' K^c_{\text{NO}_3}}{k_{\text{Cl}}' K^c_{\text{Cl}}} + \frac{k_w'' K^c_{\text{Cl}} - k_w''' K^c_{\text{NO}_3}}{k_{\text{Cl}}'' K^c_{\text{Cl}}} [\text{Cl}^-] \quad (15)$$

From the slopes (Figure 5) we have

$$\frac{k_w'' K^c_{\text{NO}_3} - k_w'' K^c_{\text{Cl}}}{k_{\text{NO}_3}''' K^c_{\text{NO}_3}} = 0.39$$

$$\frac{k_w'' K^c_{\text{NO}_3} - k_w'' K^c_{\text{Cl}}}{k_{\text{Cl}}'' K^c_{\text{Cl}}} = 0.93$$

whence

$$\frac{k_{\text{NO}_3}''' K^c_{\text{NO}_3}}{k_{\text{Cl}}'' K^c_{\text{Cl}}} = 2.4 \quad (16)$$

From the intercepts ( $[\text{NO}_3^-] = 0$ ,  $[\text{Cl}^-] = 1.0$ ) we have

$$\frac{k_w + k_w'' K^c_{\text{Cl}}}{k_{\text{NO}_3}''' K^c_{\text{NO}_3}} = 1.63 \quad \frac{k_w + k_w'' K^c_{\text{Cl}}}{k_{\text{Cl}}'' K^c_{\text{Cl}}} = 3.36$$

whence

$$\frac{k_{\text{NO}_3}''' K^c_{\text{NO}_3}}{k_{\text{Cl}}'' K^c_{\text{Cl}}} = 2.1 \quad (17)$$

Table VI. Competition at Constant Ionic Strength<sup>a</sup>

X <sup>-</sup>	Y <sup>-</sup>	$(k_w + k_w''K_x^c)/k_y'''K_y^c$	$(k_w'''K_y^c - k_w''K_x^c)/k_y'''K_y^c$
ClO <sub>4</sub> <sup>-</sup>	Cl <sup>-</sup>	3.77	-0.41
ClO <sub>4</sub> <sup>-</sup>	NO <sub>3</sub> <sup>-</sup>	2.40 <sup>b</sup>	+0.17 <sup>b</sup>
CF <sub>3</sub> SO <sub>3</sub> <sup>-</sup>	Cl <sup>-</sup>	2.64	+0.72
CF <sub>3</sub> SO <sub>3</sub> <sup>-</sup>	NO <sub>3</sub> <sup>-</sup>	1.56	+0.56

<sup>a</sup> Competition by Y with supporting electrolyte X where [X<sup>-</sup>] + [Y<sup>-</sup>] = 1.0 mol dm<sup>-3</sup>. <sup>b</sup> From a least-squares fit of the data of Jackson et al.<sup>2b</sup>

## Scheme III

in reasonable agreement with (16).

For the constant ionic strength data [Y<sup>-</sup>] + [ClO<sub>4</sub><sup>-</sup>] = 1.0 mol dm<sup>-3</sup> the left-hand species in Scheme II is replaced by ClO<sub>4</sub><sup>-</sup>, CoN<sub>3</sub><sup>2+</sup> and the right-hand species by Y<sup>-</sup>, CoN<sub>3</sub><sup>2+</sup>. The former will result in only CoOH<sub>2</sub><sup>3+</sup> product even though some capture of ClO<sub>4</sub><sup>-</sup> is likely.<sup>26</sup> Then

$$\frac{1}{R_y} = \frac{k_w + k_w''K_{\text{ClO}_4}^c}{k_y'''K_y^c} + \frac{k_w'''K_y^c - k_w''K_{\text{ClO}_4}^c}{k_y'''K_y^c} [\text{Y}^-] \quad (18)$$

Data for the case [Y<sup>-</sup>] + [CF<sub>3</sub>SO<sub>3</sub><sup>-</sup>] = 1.0 mol dm<sup>-3</sup> may be treated in the same way since formation of CoOSO<sub>2</sub>CF<sub>3</sub><sup>2+</sup> leads almost entirely to CoOH<sub>2</sub><sup>3+</sup>.<sup>30</sup>

Values of the slopes and intercepts (Figure 5) are given in Table VI.

The mechanism simplifies in the absence of a supporting electrolyte (*I* variable). (See Scheme III.) Again, provided  $k_o^* = k_y^*$

$$\begin{aligned}
 R_y &= \frac{[\text{CoY}^{2+}]}{[\text{CoOH}_2^{3+}][\text{Y}^-]} = \frac{k_y''K_y^c}{k_w + k_w''K_y^c} \\
 \frac{1}{R_y} &= \frac{k_w}{k_y''K_y^c} + \frac{k_w''}{k_y''} [\text{Y}^-] \quad (19)
 \end{aligned}$$

From the slopes of the linear portions of Figure 6 we have  $k_w''/k_{\text{Cl}^-} = 1.43$  and  $k_w''/k_{\text{NO}_3^-} = 0.8$  whence the division of the ion-paired species between water entry and anion entry is 60% CoOH<sub>2</sub><sup>3+</sup>, 40% CoCl<sup>2+</sup> for the chloride ion pair and 44% CoOH<sub>2</sub><sup>3+</sup>, 56% CoNO<sub>3</sub><sup>2+</sup> for the nitrate ion pair. The intercepts give  $k_w/k_{\text{Cl}^-}K_{\text{Cl}^-}^c = 1.9$  and  $k_w/k_{\text{NO}_3^-}K_{\text{NO}_3^-}^c = 1.2$  whence  $k_{\text{NO}_3^-}K_{\text{NO}_3^-}^c/k_{\text{Cl}^-}K_{\text{Cl}^-}^c = 1.6$ . This latter value is in good agreement with the values obtained at constant ionic strength (eq 16 and 17), considering the different slopes and intercepts involved, and this supports the approach taken. Both sets of data (i.e., *I* constant or variable) allow ratios of rate parameters (i.e.,  $k_{\text{NO}_3^-}/k_{\text{Cl}^-}$ ) or ratios of equilibrium constants (i.e.,  $K_{\text{NO}_3^-}^c/K_{\text{Cl}^-}^c$ ) to be evaluated, provided  $k_w''$  for entry of water into the different ion-paired species is the same; i.e.,  $k_w''' = k_w''$ . However the two sets of data do not agree on this score, which implies that  $k_w''' \neq k_w''$ . Apparently entry of water into the ion pair is itself influenced by the nature of the ion pair. This is not unreasonable because steric factors will play an important role here. A solution to this problem and a way

of obtaining relative  $k_{\text{NO}_3^-}$ ,  $k_{\text{Cl}^-}$ , and  $k_w''$  data would exist if reliable  $K_y^c$  values were available.

**Comparisons with Related Induced Reactions.** Finally we wish to comment briefly on some similarities, and some differences, between the reaction of ONY with CoN<sub>3</sub><sup>2+</sup> and the related rapid reactions of the two-electron oxidizing reagents Cl<sub>2</sub>, H<sub>2</sub>O<sub>2</sub>, HOCl, O<sub>3</sub>, and S<sub>2</sub>O<sub>8</sub><sup>2-</sup> with CoX<sup>2+/3+</sup> species (X = I<sup>-</sup>, Br<sup>-</sup>, DMSO).<sup>28,29</sup> All can be considered as oxidative processes on the coordinated group, reactions 20–23. Whereas

for (20) and (21) there is clear evidence for the direct incorporation of the reduced part of the oxidizing agent (i.e., hydrolysis of the oxidized 3+ intermediate is unimportant), this is not so for reaction 23. Presumably CoN<sub>4</sub>OCl<sup>2+</sup> easily cleaves to CoN<sub>2</sub>O<sup>3+</sup> + N<sub>2</sub> + Cl<sup>-</sup> and the dinitrogen oxide species provides an excellent leaving group; at no stage is there a rearrangement process resulting in the formation of a Co–Cl bond. Direct incorporation of Cl from Cl<sub>2</sub> and OH from H<sub>2</sub>O<sub>2</sub> eliminates subsequent 5-coordinate intermediates for the CoBrCl<sup>3+</sup> and CoIOH<sup>3+</sup> species, but similar direct evidence is lacking for reaction 23. All we can be relatively sure of from this study is that, if Co<sup>3+</sup> is formed, it must react with its immediate environment; that is, it has an extremely short lifetime (<10<sup>-9</sup> s). The CoIOH<sup>3+</sup>-type intermediates apparently exist for much longer, long enough to equilibrate with the solvent and associate with anions from the bulk solution (Cl<sup>-</sup>; HSO<sub>4</sub><sup>-</sup>).<sup>28</sup> The ion pair Cl<sup>-</sup>, CoIOH<sup>3+</sup> then decomposes with substantial entry of Cl<sup>-</sup>, >90% CoCl<sup>2+</sup> being formed at 0.2 mol dm<sup>-3</sup> Cl<sup>-</sup>. As for reaction 23, Cl<sup>-</sup> does not affect the rate of reaction, but the large amount of CoCl<sup>2+</sup> formed implies that in some way it assists the loss of the oxidized ligand. Also the “*P* plot” is not linear (Figure 2 of ref 28) but an *R*<sup>-1</sup> vs. [Cl<sup>-</sup>] plot bears some resemblance to Figure 6. O<sub>3</sub>, S<sub>2</sub>O<sub>8</sub><sup>2-</sup>, and CH<sub>3</sub>CO<sub>3</sub>H show similar oxidizing properties toward CoX<sup>2+</sup> species, but more detail needs to be obtained for these processes.

In summary there seems to be no evidence to support 5-coordinate intermediates in reactions 20–23, but preassociation processes seem fairly well established. Entry of H<sub>2</sub>O or Y<sup>-</sup> occurs from within ion-paired intermediates. Depending on the particular oxidizing agent the intermediate can exist for long enough to be in equilibrium with the solvent, or, if it does not, it must accept those entering groups that are immediately available to it. In the former instance a chemically based selection process will operate; in the latter selection will be forced by prior events.

**Acknowledgment.** The authors wish to thank Dr. W. G. Jackson for helpful criticism of the manuscript.
