### Introduction

Cerium(IV) is a popular oxidant in analytical<sup>1</sup> and organic<sup>2</sup> applications, because it is highly reactive, inexpensive, and readily available in high purity. Ce<sup>IV</sup> has also been used as oxidant in studies of the homogeneously<sup>3</sup> and heterogeneously<sup>4</sup> catalyzed oxidations of H<sub>2</sub>O to O<sub>2</sub> and Cl<sup>-</sup> to Cl<sub>2</sub>. These systems are convenient because the direct oxidations of H<sub>2</sub>O and Cl<sup>-</sup> by Ce(IV) are relatively slow. The Ce<sup>IV</sup>/Ce<sup>III</sup> potential is well established in aqueous H<sub>2</sub>SO<sub>4</sub>, HNO<sub>3</sub>, and HClO<sub>4</sub>.<sup>5–7</sup> In hydrochloric acid, however, much less information is available. The potential for Ce<sup>IV</sup>/Ce<sup>III</sup> in 1 M HCl was initially reported to be 1.28 V vs NHE,<sup>7</sup> but this result was later called into question.<sup>8</sup> Nevertheless, the 1.28-V value is still quoted, with the original reference, in electrochemical compilations.<sup>9</sup>

Our interest in the Ce<sup>IV</sup>/Ce<sup>III</sup> couple in HCl(aq) arises from reaction 1, which is known to proceed spontaneously in the forward

direction.<sup>10,11</sup> We recently discovered that the reaction is catalyzed by ReCl<sub>6</sub><sup>2-</sup>.<sup>12</sup> In the course of studying this catalytic process, we attempted to measure the Ce<sup>IV</sup>/Ce<sup>III</sup> potential both by electrochemical means and by direct determination of the equilibrium quotient  $K_1$  for reaction 1. The latter method proved to be successful;  $K_1$  is  $47 \pm 13 \text{ atm}^{1/2} \text{ M}^{-1}$  in 1 M HCl ( $\mu = 1.2 \text{ M}$ ), which yields a Ce<sup>IV</sup>/Ce<sup>III</sup> formal potential of  $1.466 \pm 0.008 \text{ V}$  vs NHE.

### Experimental Section

**Instrumentation.** Electronic absorption spectra were recorded by using an Aviv Model 14DS spectrophotometer. Cyclic voltammograms were recorded by using either a PAR Model 174A polarographic analyzer or a Wenking TS70/1 potentiostat with a home-built microcomputer

interface. The cell contained a glassy-carbon working electrode (which was polished immediately before each measurement), a Pt counter electrode, and an aqueous Ag/AgCl (3 M NaCl) reference electrode.

**Materials and Procedures.** The molarity (M, or mol L<sup>-1</sup>) scale was used for concentrations throughout this work, except that the estimation of activity coefficients (see below) required that some molalities ( $m$ , or mol (kg of H<sub>2</sub>O)<sup>-1</sup>) be determined.

Cerium(IV) was obtained in solution form (ca. 0.5 M in 6 M HClO<sub>4</sub>) from GFS Chemicals. Other materials were reagent grade and were used as received. Acid solutions were standardized against NaOH(aq) (Merck Titrisol). The total cerium concentration in the stock solution was determined by inductively coupled plasma-atomic emission spectroscopy (Hazen Research Inc., Golden, CO), to be  $0.518 \pm 0.026 \text{ M}$ .<sup>13</sup> This solution was diluted with water and HClO<sub>4</sub>(aq) as needed to prepare "working solutions" of Ce(IV) (0.0207 or 0.0863 M) in 1 M HClO<sub>4</sub>. "Working solutions" of Ce(III) with the same concentrations were prepared similarly, except that the Ce(IV) was first reduced to Ce(III) by treatment with H<sub>2</sub>O<sub>2</sub>(aq) and the solution boiled to destroy excess H<sub>2</sub>O<sub>2</sub>, before dilution.

Measurements of  $K_1$  were carried out by mixing 0.60 mL of the above "working solutions" of Ce(IV) or Ce(III) with 2.40 mL of one of the following solutions: 1.00 M HCl/0.25 M NaCl, 1.25 M NaCl, or 1.00 M HClO<sub>4</sub>/0.25 M NaCl. (These mixtures allowed us to vary [H<sup>+</sup>] and [Cl<sup>-</sup>] at a constant ionic strength of 1.20 M and gave a total Ce concentration of either  $4.14 \times 10^{-3}$  or  $1.73 \times 10^{-2} \text{ M}$ ; see Table I.) In each run, three solutions were used: one beginning with Ce(III), one beginning with Ce(IV), and one "blank" (i.e. of the same acid mixture, but without Ce). All three solutions were saturated with Cl<sub>2</sub>(g) several times over the next 1–18 h. After the two Ce-containing solutions appeared to have reached equilibrium, their absorbances at 380 and 400 nm were recorded and (after "blank" subtraction) used to determine the equilibrium Ce(IV) concentration. (The wavelengths 380 and 400 nm were chosen so as to minimize interference from Cl<sub>2</sub>(aq), which absorbs very strongly in the region of the Ce<sup>IV</sup> absorbance maximum near 300 nm.) All experiments were performed in triplicate, and the resulting sample standard deviations for  $K_1$  and  $E^\circ(\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}})$  are reported as uncertainties in Table I. (The effects of other sources of error, including uncertainties in total Ce concentration and in extinction coefficients, on calculated values for  $K_1$  and  $E^\circ(\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}})$  are small compared to the variations between runs in measured [Ce<sup>IV</sup>] at equilibrium.)

The extinction coefficients for Ce<sup>IV</sup> in the above Cl<sup>-</sup>-containing solutions, which were needed for calculating  $K_1$ , could not be determined simply by measuring their spectra after a known dilution from the Ce(IV) stock solution. This is because significant loss of Ce(IV) occurs between the time the solutions are mixed and the earliest possible time a spectrum can be recorded. Instead, while the spectrum was being recorded, a 0.2-mL aliquot of the solution was withdrawn and the reaction was quenched by addition to 2.5 mL of 6 M H<sub>2</sub>SO<sub>4</sub>, followed by dilution to 5 mL with H<sub>2</sub>O. (A similar procedure was used by Duke and Borchers to measure [Ce(IV)] in their kinetic studies of the oxidation of Cl<sup>-</sup> by

(13) The concentration of Ce<sup>IV</sup> in the same stock solution was determined by titration to be  $0.492 \pm 0.001 \text{ M}$ . However, for all of the equilibrium quotient calculations, it is the total concentration of Ce that is important, since the amounts of Ce(III) and Ce(IV) change during treatment with Cl<sub>2</sub> and HCl(aq).

Ce(IV).<sup>11a</sup>) In separate experiments with solutions prepared from solid  $(\text{NH}_4)_2\text{Ce}(\text{NO}_3)_6(\text{s})$  (whose purity was established by titration), we found that  $\epsilon_{316\text{ nm}}(\text{CeIV}) = 6180 \pm 80 \text{ M}^{-1} \text{ cm}^{-1}$  in 3 M  $\text{H}_2\text{SO}_4$ .<sup>14</sup> This procedure enabled us to determine the Ce(IV) extinction coefficients for each different set of  $\text{H}^+$  and  $\text{Cl}^-$  concentrations, and for two different  $\text{Ce}^{\text{IV}}$  concentrations differing by at least a factor in 4 in each case. The results are presented in Table I.

Partial pressures of  $\text{Cl}_2$  over the solutions were obtained by subtracting the partial pressure of water vapor over the solution<sup>15</sup> from the current barometric pressure.

We calculated formal potentials  $E^\circ(\text{Cl}_2)$  on the molar scale for the  $\text{Cl}_2/\text{Cl}_3^-/\text{Cl}^-$  electrode under our conditions (i.e. the emf of the cell  $\text{Pt}|\text{H}_2(1 \text{ atm})|\text{HCl}(\text{aq})|\text{Cl}_2(1 \text{ atm})|\text{Pt}$ , including the effects of the formation of  $\text{Cl}_3^-$ ). For this calculation, we used the formula  $E^\circ(\text{Cl}_2) = E_m^\circ + (RT/F) \ln((1 + K_{\text{Cl}_3^-})/(m_{\text{H}^+}m_{\text{Cl}^-}\gamma_{\pm}^2))$ , derived from the work of Mussini et al.<sup>16</sup> In this formula,  $E_m^\circ$  is the standard molal electrode potential for the  $\text{Cl}_2/\text{Cl}^-$  couple ( $1.35952 \pm 0.00003 \text{ V}$  vs NHE at  $24^\circ\text{C}$ ),  $K_{\text{Cl}_3^-}$  is the equilibrium constant for the reaction  $\text{Cl}_2(\text{g}) + \text{Cl}^-(\text{aq}) \leftrightarrow \text{Cl}_3^-(\text{aq})$  ( $0.0124 \text{ atm}^{-1}$  at  $24^\circ\text{C}$ ),  $m_{\text{H}^+}$  and  $m_{\text{Cl}^-}$  are the molalities of  $\text{H}^+$  and  $\text{Cl}^-$ , and  $\gamma_{\pm}$  is the mean molal activity coefficient for  $\text{HCl}(\text{aq})$ . Values of  $\gamma_{\pm}$  for these solutions were estimated using published activity coefficients for pure  $\text{HCl}(\text{aq})$ <sup>17</sup> and Harned  $\alpha$  coefficients<sup>18,19</sup> and the molalities of our solutions, which we determined from their known molalities by measuring their densities. The resulting values of  $E^\circ(\text{Cl}_2)$  ( $\mu = 1.20 \text{ M}$ , with  $\text{Na}^+$  and  $\text{ClO}_4^-$  balancing ions) are  $1.3673 \text{ V}$  ( $1.00 \text{ M H}^+$ ,  $1.00 \text{ M Cl}^-$ ),  $1.3703 \text{ V}$  ( $0.20 \text{ M H}^+$ ,  $1.00 \text{ M Cl}^-$ ), and  $1.3654 \text{ V}$  ( $1.00 \text{ M H}^+$ ,  $0.20 \text{ M Cl}^-$ ) vs NHE. (These values are believed to be accurate within ca.  $0.1 \text{ mV}$ ; the largest single source of error is likely to be the estimation of  $\gamma_{\pm}$ .)

## Results and Discussion

**Electrochemical Determination of  $E(\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}})$ .** The  $\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}$  potential has been measured successfully in  $\text{HClO}_4$ ,  $\text{H}_2\text{SO}_4$ , and  $\text{HNO}_3$  solutions by electrochemical methods.<sup>6,7</sup> Smith and Goetz<sup>7</sup> also attempted to measure the potential in 1 M  $\text{HCl}$ , reporting a value of  $1.28 \text{ V}$  vs NHE. We also attempted to determine the  $\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}$  potential, by measuring the rest potential of a glassy-carbon electrode in various mixtures of  $\text{Ce}^{\text{III}}$  and  $\text{Ce}^{\text{IV}}$  in 1 M  $\text{HCl}$  (these were examined immediately after preparation, to minimize decomposition of  $\text{Ce}^{\text{IV}}$ ). Our measurements suggested a  $\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}$  potential of  $\geq 1.5 \text{ V}$  vs NHE. Unfortunately, both this result and the older  $1.28\text{-V}$  value are likely to be in error, because (as pointed out in ref 8) the  $\text{Cl}_2/\text{Cl}^-$  couple is also electroactive under these conditions.

We also attempted to use cyclic voltammetry to obtain the half-wave potential for the  $\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}$  couple. (We reasoned that voltammograms recorded using a glassy-carbon electrode, which shows a high overpotential for  $\text{Cl}_2$  evolution, might yield a single wave attributable to  $\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}$ .<sup>20</sup>) This attempt also failed: we found no waves attributable to  $\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}$  at a variety of scan rates ( $10\text{--}500 \text{ mV s}^{-1}$ ).

**Chemical Method, via  $K_1$ .** Since several electrochemical methods had failed, we attempted a chemical approach. If equilibrium can be achieved in reaction 1, the  $\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}$  potential can be calculated from  $K_1$ . We have now determined  $K_1$  under several sets of conditions, by measuring spectrophotometrically the equilibrium concentration of  $\text{Ce}^{\text{IV}}$  in mixtures containing  $\text{Ce}$ ,  $\text{Cl}^-$ , and  $\text{Cl}_2$ . The results of these experiments are presented in Table I.

We ensured that equilibrium was achieved in these experiments by passing  $\text{Cl}_2$  into separate solutions initially containing only  $\text{Ce}^{\text{III}}$  or only  $\text{Ce}^{\text{IV}}$ . Over a period of 1–18 h (depending on the concentrations of  $\text{H}^+$  and  $\text{Cl}^-$  chosen), the absorbances in the “ $\text{Ce}^{\text{III}}$ ” and “ $\text{Ce}^{\text{IV}}$ ” solutions converged to common values. Therefore, the mixtures must have arrived at equilibrium.

The Nernst equation applied to reaction 1, including activity effects (assuming unit activity coefficient for  $\text{Cl}_2(\text{g})$ ), is

$$E_1 = E_1^\circ - (RT/nF) \ln\{a_{\text{Ce}^{\text{III}}}(\text{P}_{\text{Cl}_2})^{1/2}/a_{\text{Ce}^{\text{IV}}}a_{\text{Cl}^-}\} \quad (2)$$

At equilibrium,  $E_1$  is zero and

$$E_1^\circ = (RT/nF) \ln\{a_{\text{Ce}^{\text{III}}}(\text{P}_{\text{Cl}_2})^{1/2}/a_{\text{Ce}^{\text{IV}}}a_{\text{Cl}^-}\} \quad (3)$$

Some activity coefficients have been measured for solutions of  $\text{Ce}(\text{III})$  in hydrochloric acid.<sup>18</sup> However, as far as we are aware, no such data are available for cerium(IV). Thus, we have carried out the remainder of our analysis using the formal potential  $E_1^\circ$  on the molar scale, which is based on concentrations rather than activities:<sup>21</sup>

$$E_1^\circ = (RT/nF) \ln\{[\text{Ce}^{\text{III}}](\text{P}_{\text{Cl}_2})^{1/2}/([\text{Ce}^{\text{IV}}][\text{Cl}^-])\} = (RT/nF) \ln(K_1) \quad (4)$$

Then, since  $E_1^\circ$  is the difference between the formal potentials for the  $\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}$  couple and the  $\text{Cl}_2/\text{Cl}_3^-/\text{Cl}^-$  system<sup>16</sup> (see Experimental Section), the desired quantity  $E^\circ(\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}})$ , presented in Table I, is given by

$$E^\circ(\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}) = (RT/nF) \ln(k_1) + E^\circ(\text{Cl}_2) \quad (5)$$

The equilibrium quotient data in Table I show relatively large uncertainties (ca.  $\pm 25\%$ ).<sup>22</sup> Still, the corresponding uncertainties in the calculated  $\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}$  formal potentials are less than  $0.01 \text{ V}$ , and as a result, the trends in  $E^\circ(\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}})$  with  $[\text{H}^+]$  and  $[\text{Cl}^-]$  are clear.

$E^\circ(\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}})$  is smaller at  $[\text{H}^+] = 0.2 \text{ M}$  than at  $[\text{H}^+] = 1 \text{ M}$ . This suggests that  $\text{Ce}(\text{IV})$  can be stabilized in these solutions by hydrolysis, i.e. by formation of hydroxo complexes. The higher value of  $E^\circ(\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}})$  at  $[\text{Cl}^-] = 0.2 \text{ M}$  suggests that complexation by chloride ion also stabilizes  $\text{Ce}(\text{IV})$ . Both of these trends are consistent with previous work: Hydrolysis of  $\text{Ce}(\text{IV})$  in  $\text{HClO}_4$  solution has been studied by several other workers;<sup>23,24</sup> complexation of  $\text{Ce}(\text{IV})$  by other ions, such as  $\text{SO}_4^{2-}$ , has also been demonstrated.<sup>25</sup> Thus, it is likely that  $\text{Ce}^{\text{IV}}(\text{OH})\text{Cl}_x^{x-3}$ , or similar species, are important in the chemistry of cerium(IV) in hydrochloric acid.<sup>26</sup>

- (14) As a check, we also performed this procedure with the final solution  $0.5 \text{ M}$  in  $\text{H}_2\text{SO}_4$ . This gave an extinction coefficient of  $5620 \pm 50 \text{ M}^{-1} \text{ cm}^{-1}$ , in close agreement with the literature value of  $5580 \text{ M}^{-1} \text{ cm}^{-1}$ : Medalia, A. I.; Byrne, B. J. *Anal. Chem.* **1951**, *23*, 453–456.

- (20) We recently used cyclic voltammetry to measure the  $\text{ReCl}_6^{-/2-}$  half-wave potential, ca.  $1.70 \text{ V}$  vs NHE (also well beyond the  $\text{Cl}_2/\text{Cl}^-$  potential) in 1 M  $\text{HCl}$ .<sup>12</sup>

- (21) Bard, A. J.; Faulkner, L. R. *Electrochemical Methods: Fundamentals and Applications*; Wiley: New York, 1980; pp 51–52.
- (22) This variability may be due to differences in the efficiency of saturating the solutions with  $\text{Cl}_2$ : Runs in which the background absorbance due to  $\text{Cl}_2$  was smaller also tended to show smaller net absorbance due to  $\text{Ce}(\text{IV})$ . However, more prolonged or more frequent saturation with  $\text{Cl}_2$  did not improve the reproducibility of the data. There was no noticeable correlation between the temperature of a run, or the barometric pressure, and the measured  $[\text{Ce}(\text{IV})]$  value.
- (23) (a) Sherrill, M. S.; King, C. G.; Spooner, R. C. *J. Am. Chem. Soc.* **1943**, *65*, 170–179. (b) Hardwick, T. J.; Robertson, E. *Can. J. Chem.* **1951**, *29*, 818–822.
- (24) Hardwick and Robertson<sup>23b</sup> also found evidence for dimerization of  $\text{Ce}(\text{IV})$  complexes. Our data (see Table I) show little change in  $E^\circ$  at higher total Ce concentration. This suggests that dimerization, if it occurs in our system, has little effect on redox properties.
- (25) Hardwick, T. J.; Robertson, E. *Can. J. Chem.* **1951**, *29*, 828–837.

To summarize, we have used a chemical method to obtain the first reliable estimate for the  $\text{Ce}^{\text{IV}}/\text{Ce}^{\text{III}}$  redox potential in

- (26) Solutions of  $\text{Ce}(\text{IV})$  in conc.  $\text{HCl}(\text{aq})$  are orange-red,<sup>11b</sup> and the electronic spectrum of  $\text{CeCl}_6^{2-}$  shows  $\lambda_{\text{max}} = 376 \text{ nm}$  (Ryan, J. L.; Jørgensen, C. K. *J. Phys. Chem.* **1966**, *70*, 2845–2857). Both of these observations represent large red shifts relative to our spectra. Thus, we believe the number of chloride ions complexed to  $\text{Ce}(\text{IV})$  under our conditions is small. (The equilibrium constants for binding of  $\text{Cl}^-$  to the isoelectronic  $\text{Th}^{4+}$  are all less than  $2 \text{ M}^{-1}$ : Waggener, W. C.; Stoughton, R. W. *J. Phys. Chem.* **1952**, *56*, 1–5.)

hydrochloric acid solution. Our results are consistent with previous reports of the reactivity of  $\text{Ce}^{\text{IV}}$  in  $\text{HCl}(\text{aq})$ , and they suggest that these solutions contain complexes of  $\text{Ce}^{\text{IV}}$  with  $\text{Cl}^-$  and  $\text{OH}^-$ .
