## Some Chemistry of Difluorodiazine

By MAX LUSTIG

Received July 31, 1964

Difluorodiazine undergoes reaction with some sulfur oxides and sulfur and phosphorus fluorides and oxyfluorides. These reactions are characterized by fluorination or fluorination with oxygen elimination. The quantitative syntheses of difluoroamidodisulfonyl fluoride,  $\text{FSO}_2\text{NF}_2$ , and pentafluorosulfur difluoramine,  $\text{SF}_5\text{NF}_2$ , and a high yield preparation of sulfonyl bromide fluoride,  $\text{FSO}_2\text{Br}$ , are given. The isomerization of *trans*- $\text{N}_2\text{F}_2$  was accomplished at a temperature lower than formerly described.

### Introduction

The isomers of difluorodiazine,  $\text{N}_2\text{F}_2$ , were first prepared by Haller in 1942<sup>1</sup> and later by others using various routes.<sup>2-6</sup> Besides an investigation of the relative reactivity of the isomers of  $\text{N}_2\text{F}_2$  toward glass, mercury, and copper<sup>2</sup> and the observation that difluorodiazine behaves as a free radical source for the initiation of polymerization<sup>2</sup> and the cross linking of polymers,<sup>7</sup> virtually nothing is known of the chemistry of  $\text{N}_2\text{F}_2$ . To characterize more fully the chemical behavior of this reagent with substrates other than organic monomers, the compounds sulfur dioxide, sulfur trioxide, thionyl fluoride, sulfur tetrafluoride, disulfur decafluoride, phosphoryl fluoride, phosphorus trifluoride, fluorine fluorosulfonate, peroxydisulfonyl difluoride, and cesium fluorosulfonate were selected in this investigation. Use of these substrates allowed further characterization of the chemical behavior of  $\text{N}_2\text{F}_2$ .

### Experimental

**Reagents.**—The sulfur dioxide in cylinder form and sulfur trioxide as "Sulfan B" were obtained from the General Chemical Division of the Allied Chemical Corp. The sulfur tetrafluoride was obtained from E. I. du Pont de Nemours and Co. in a cylinder. The thionyl fluoride was obtained from the sulfur tetrafluoride by allowing the latter to stand 0.5 hr. in moist air in a Pyrex vacuum apparatus and was purified by passing it through a trap maintained at  $-145^\circ$  which retained the pure reagent. Cylinders of phosphorus trifluoride and phosphoryl fluoride were received from the Ozark-Mahoning Co. These commercially secured materials were of high purity and used without further purification. Peroxydisulfonyl difluoride<sup>8</sup> and fluorine fluorosulfonate<sup>9</sup> were prepared by literature methods. The disulfur decafluoride was prepared by fluorination of flowers of sulfur at  $-78^\circ$ . The cesium fluorosulfonate was prepared by heating dry  $\text{CsF}$ , from Penn Rare Metals, Inc., at  $100^\circ$  for 1 day with excess  $\text{SO}_3$ . The excess  $\text{SO}_3$  was removed by pumping *in vacuo* at  $100^\circ$ . The difluorodiazine mixture (95% *cis*, 4% *trans* isomer and 1%  $\text{N}_2\text{O}$ ) and the tetrafluorohydrazine (99%  $\text{N}_2\text{F}_4$  and 1%  $\text{NO}$ ) were obtained from Air Products and Chemicals, Inc. The

composition of the last two reagents was determined by mass spectral analysis.

**Equipment and General Procedure.**—A standard Pyrex glass vacuum apparatus was used for transferring gaseous materials and for obtaining pressure-volume information. The difluorodiazine cylinder was barricaded behind concrete and handled remotely. Prefluorinated stainless steel or Monel cylinders equipped with the corresponding Teflon-packed stainless steel or Monel Hoke valves were generally used as reactors for studies above room temperature although these were attacked slowly by *cis*- $\text{N}_2\text{F}_2$  at  $95^\circ$  to yield  $\text{N}_2$  and metal fluorides. At elevated temperatures neither Pyrex nor Teflon vessels could be satisfactorily used due to formation of  $\text{N}_2\text{O}$  and  $\text{SiF}_4$  in the former and fluorocarbons in the latter. No differences in the reactions were observed when either Monel or stainless steel was used. In the study involving  $\text{SO}_3$ , however, Pyrex reactors were also used. All gaseous reactants were condensed into the reactors at  $-196^\circ$  and were allowed to warm to ambient temperature. The reactors were then placed in oil baths set at the required temperatures.

The mass spectrograph (Consolidated Engineering Corp. 21-620 with heated source at  $200^\circ$ ), calibrated using pure gaseous samples, and an infrared spectrophotometer (Perkin-Elmer Infracord) were used for product identification and determination of mole per cent composition. This information, together with *PVT* data, was used to determine the quantity of each species present in the mixture. Conditions were chosen such that all the products were gaseous. Reaction of  $\text{SF}_4$ ,  $\text{PF}_5$ , and  $\text{SO}_3$  in the inlet system prevented use of the mass spectrometer for analysis of these gases. Analyses of these substances, however, could be obtained from the abundances of the other products found and from *PVT* data. The values placed in parentheses shown below represent the number of millimoles, and they are generally accurate to within 2-3% relative, but those for  $\text{SF}_4$ ,  $\text{PF}_5$ , and  $\text{SO}_3$  may be less accurately known. When aliquots were taken for analysis at various stages of a reaction, the results shown are compensated for the known fractions removed. The values are also compensated for the  $\text{N}_2\text{O}$  initially present in the  $\text{N}_2\text{F}_2$ . Small quantities of reagents were used due to the hazardous nature of  $\text{N}_2\text{F}_2$ .

**Reactions with  $\text{SO}_2$ .**—In a preliminary experiment a 10-ml. copper tube was loaded with equimolar quantities of  $\text{N}_2\text{F}_2$  and  $\text{SO}_2$  such that the total pressure at room temperature was about 80 atm. The temperature was raised slowly in an electrically controlled heater and at  $102^\circ$  the mixture exploded. In a subsequent attempt, sulfur dioxide (0.25) and  $\text{N}_2\text{F}_2$  (0.25) were charged into a 75-ml. stainless steel cylinder. After standing 1.5 hr. at  $100^\circ$ , some reaction did take place. Analysis:  $\text{N}_2\text{F}_2$  (0.12),  $\text{N}_2\text{O}$  (0.05),  $\text{SOF}_2$  (0.04),  $\text{N}_2$  (0.10),  $\text{SO}_2$  (0.14),  $\text{SO}_2\text{F}_2$  (0.05),  $\text{S}_2\text{O}_5\text{F}_2$  (0.01), and  $\text{SOF}_4$  (trace). The mixture was allowed to stand an additional 17 hr. at  $100^\circ$ . Analysis: *trans*- $\text{N}_2\text{F}_2$  (0.01),  $\text{N}_2$  (0.14),  $\text{N}_2\text{O}$  (0.09),  $\text{SO}_2$  (0.07),  $\text{SOF}_2$  (0.08), and  $\text{SO}_2\text{F}_2$  (0.08).

**Addition of  $\text{N}_2\text{F}_4$ .**—Difluorodiazine and  $\text{N}_2\text{F}_4$  (0.52 each) together with  $\text{SO}_2$  (0.62) were charged into a 150-ml. Monel

cylinder. The mixture was heated at 100° for 21 hr. Analysis: FSO<sub>2</sub>NF<sub>2</sub> (0.63), NF<sub>3</sub> (0.11), N<sub>2</sub>F<sub>4</sub> (0.15), N<sub>2</sub>F<sub>2</sub> (0.12), N<sub>2</sub> (0.40), and traces of N<sub>2</sub>O and NO.

**Addition of Br<sub>2</sub>.**—Difluorodiazine (0.53), SO<sub>2</sub> (1.07), and Br<sub>2</sub> (0.52) were loaded into a 150-ml. stainless steel reactor and heated at 100° for 24 hr. Analysis: FSO<sub>2</sub>Br (0.89), SO<sub>2</sub>F<sub>2</sub> (0.08), SO<sub>2</sub> (0.10), N<sub>2</sub> (0.53), O<sub>2</sub> (0.03), and Br<sub>2</sub> (0.05).

**Additional Characterization of FSO<sub>2</sub>Br.**—Sulfuryl bromide fluoride shows infrared bands at 6.89 (s), 8.12 (s), and 12.3 (br, vs)  $\mu$  assigned to the asymmetric and symmetric S=O stretching frequencies and the S—F stretching frequency, respectively.<sup>10</sup> It has one <sup>19</sup>F n.m.r. resonance at -120.9  $\phi$  relative to CCl<sub>3</sub>F as the internal standard. The *m/e*, species, and relative mass spectral intensities for the most prominent absorptions are 67, FSO<sup>+</sup>, 39.6; 83, FSO<sub>2</sub><sup>+</sup>, 100; 162, FSO<sub>2</sub><sup>79</sup>Br, 31.3; 164, FSO<sub>2</sub><sup>81</sup>Br, 30.8.

**Reactions with SO<sub>3</sub> in Metal.** (a) **Excess N<sub>2</sub>F<sub>2</sub>.**—Difluorodiazine (2.98) and SO<sub>3</sub> (0.43) were loaded into a 75-ml. stainless steel reactor and allowed to stand at room temperature for 1 hr. Analysis: N<sub>2</sub>O (0.26), S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> (0.17), SO<sub>2</sub>F<sub>2</sub> (0.10), and N<sub>2</sub>F<sub>2</sub> (2.72). An aliquot was removed and distilled into a 10-ml. Pyrex bulb which was allowed to stand for 17 hr. at room temperature. Only a slight decrease in the amount of S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> and increase in that of SO<sub>2</sub>F<sub>2</sub> was observed. However, the sample which was allowed to age at room temperature in the metal cylinder showed significant change. Analysis: N<sub>2</sub>O (0.40), S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> (0.05), SO<sub>2</sub>F<sub>2</sub> (0.33), and N<sub>2</sub>F<sub>2</sub> (2.54).

(b) **Excess SO<sub>3</sub>.**—Difluorodiazine (0.36) and SO<sub>3</sub> (0.48) were placed into the same cylinder as above and were heated at 100° for 17 hr. Analysis: N<sub>2</sub>O (0.27), S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> (0.22), SO<sub>2</sub>F<sub>2</sub> (0.01), SO<sub>3</sub> (small amount), and N<sub>2</sub> (0.10).

**Reactions in Pyrex Glass.** (a) **Excess SO<sub>3</sub>.**—In an experiment performed in a 115-ml. Pyrex bulb, N<sub>2</sub>F<sub>2</sub> (0.29) and a several-fold excess of SO<sub>3</sub> were allowed to stand for 1 hr. at room temperature and then were further treated at 75° for 2 hr. Analysis showed S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> (0.20), a small amount of S<sub>3</sub>O<sub>5</sub>F<sub>2</sub>, N<sub>2</sub>O (0.25), SiF<sub>4</sub>, and unreacted SO<sub>3</sub>. The S<sub>3</sub>O<sub>5</sub>F<sub>2</sub> was identified only by its infrared spectrum.

(b) **Excess N<sub>2</sub>F<sub>2</sub>.**—The N<sub>2</sub>F<sub>2</sub> (1.14) and SO<sub>3</sub> (0.38) were placed into the same reactor and then heated to 75°. The following are the quantities of S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> and SO<sub>2</sub>F<sub>2</sub> found after periodic monitoring: 2.5 hr. S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> (0.04), SO<sub>2</sub>F<sub>2</sub> (trace); 3 hr. S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> (0.05), SO<sub>2</sub>F<sub>2</sub> (>0.01); 15 hr. S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> (0.14), SO<sub>2</sub>F<sub>2</sub> (0.02); and 20 hr. S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> (0.19), SO<sub>2</sub>F<sub>2</sub> (0.03). The other materials present were unreacted SO<sub>3</sub> (except after 20 hr.) and N<sub>2</sub>F<sub>2</sub> together with N<sub>2</sub>, N<sub>2</sub>O, and SiF<sub>4</sub>.

**Reactions with SF<sub>4</sub>.**—Sulfur tetrafluoride (0.12), high purity according to infrared analysis, and N<sub>2</sub>F<sub>2</sub> (0.21) were charged into a 75-ml. stainless steel cylinder and heated at 80° for 1 hr. Mass spectral analysis indicated only a trace of SF<sub>5</sub>-containing material had been formed. The mixture was further treated at 100° for 16 hr. Analysis: S<sub>2</sub>F<sub>10</sub> (0.05), SF<sub>6</sub> (0.02), N<sub>2</sub> (0.16), N<sub>2</sub>O (0.02), and *trans*-N<sub>2</sub>F<sub>2</sub> (0.01).

**Addition of N<sub>2</sub>F<sub>2</sub>.**—Tetrafluorohydrazine (0.62), SF<sub>4</sub> (0.57), and N<sub>2</sub>F<sub>2</sub> (0.56) were charged into a 150-ml. Monel cylinder. The cylinder and contents were allowed to stand at 100° for 17 hr. Analysis: SF<sub>2</sub>NF<sub>2</sub> (0.56), N<sub>2</sub> (0.51), NF<sub>3</sub> (0.44), *trans*-N<sub>2</sub>F<sub>2</sub> (0.03), N<sub>2</sub>F<sub>4</sub> (0.15).

**Reactions with SOF<sub>2</sub>.**—The same cylinder was charged with N<sub>2</sub>F<sub>2</sub> (0.31) and SOF<sub>2</sub> (0.33) and placed in a bath set at 100° for 44 hr. Analysis: SOF<sub>4</sub> (0.17), SOF<sub>2</sub> (0.09), SO<sub>2</sub>F<sub>2</sub> (0.02), *trans*-N<sub>2</sub>F<sub>2</sub> (0.01), N<sub>2</sub>O (0.03), and N<sub>2</sub> (0.26).

**Reactions with POF<sub>3</sub>.**—POF<sub>3</sub> (0.90) and N<sub>2</sub>F<sub>2</sub> (1.18) were placed into a 150-ml. Monel cylinder. The vessel was then heated at 85° for 24 hr. Infrared analysis showed nearly complete conversion of the POF<sub>3</sub> to PF<sub>5</sub>. Analysis: PF<sub>5</sub> (0.9), N<sub>2</sub> (0.89), O<sub>2</sub> (0.44), N<sub>2</sub>O (0.04), and N<sub>2</sub>F<sub>2</sub> (0.20). The reactor was not previously used or fluorinated.

**Reactions with PF<sub>3</sub>.**—N<sub>2</sub>F<sub>2</sub> (0.78) and PF<sub>3</sub> (0.78) were charged into a 75-ml. stainless steel reactor. After standing for 17 hr. at

room temperature, infrared examination showed that most of the PF<sub>3</sub> was converted to PF<sub>5</sub>, and a small quantity of POF<sub>3</sub> was observed. Analysis: PF<sub>3</sub> (0.22), PF<sub>5</sub> (0.5), POF<sub>3</sub> (trace), N<sub>2</sub> (0.53), N<sub>2</sub>F<sub>2</sub> (0.20), and N<sub>2</sub>O (0.04).

**Attempted Reactions with S<sub>2</sub>O<sub>5</sub>F<sub>2</sub>, SO<sub>2</sub>F<sub>2</sub>, and CsOSO<sub>2</sub>F.**—Approximately 2-mmole quantities of SO<sub>2</sub>F<sub>2</sub> and S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> were allowed to contact separately with an equal quantity of *cis*-N<sub>2</sub>F<sub>2</sub> in 150-ml. Monel cylinders first at 100° for several hours and then the reactions were repeated at 150° for several hours. When CsOSO<sub>2</sub>F (5 g.) was used as the substrate the same conditions and procedure as above were employed. Only decomposition of the *cis*-N<sub>2</sub>F<sub>2</sub> was observed in every case.

**Ageing of *cis*-N<sub>2</sub>F<sub>2</sub>.**—One mmole of N<sub>2</sub>F<sub>2</sub> (containing 4% *trans*) was allowed to stand in each a Monel and a stainless steel cylinder at 100° for 24 hr. Complete decomposition to N<sub>2</sub> and metal fluorides was observed. Analysis: N<sub>2</sub> (0.97), *trans*-N<sub>2</sub>F<sub>2</sub> (0.01) in Monel; N<sub>2</sub> (0.96), *trans*-N<sub>2</sub>F<sub>2</sub> (0.01) in stainless steel.

**Ageing of *trans*-N<sub>2</sub>F<sub>2</sub>.**—A mixture containing *trans*-N<sub>2</sub>F<sub>2</sub> (0.49) and *cis*-N<sub>2</sub>F<sub>2</sub> (0.05) was charged into a 75-ml. stainless steel reactor and heated to 95° for 14 hr. Analysis: *cis*-N<sub>2</sub>F<sub>2</sub> (0.41), *trans*-N<sub>2</sub>F<sub>2</sub> (0.01), N<sub>2</sub> (0.11), and N<sub>2</sub>O (trace).

## Results and Discussion

It has been shown in this work that *cis*-N<sub>2</sub>F<sub>2</sub> can behave (1) as a fluorination agent or (2) both as a deoxygenation and fluorination agent depending upon the nature of the substrate. An example of each reaction type has been provided previously by the behavior of the isomeric mixture toward metal at elevated temperatures and by the behavior of *cis*-N<sub>2</sub>F<sub>2</sub> toward glass.<sup>2</sup> Reaction type 1 may also account for its free radical polymerization initiation and cross linking of polymers such as the Viton fluoroelastomers.<sup>7</sup> Both types of polymer reactions presumably involve the fluorination of a double bond to form the intermediate >C—C<F radical which may then form polymerized or cross-linked products.

Sulfur dioxide undergoes both types of reaction with *cis*-N<sub>2</sub>F<sub>2</sub> on standing at 100° in a stainless steel cylinder to give as principal products SO<sub>2</sub>F<sub>2</sub>, SOF<sub>2</sub>, N<sub>2</sub>O, and N<sub>2</sub> and the transit minor products, S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> and SOF<sub>4</sub>. The intermediary appearance of S<sub>2</sub>O<sub>5</sub>F<sub>2</sub> is unexplained. It disappears as a result of a subsequent reaction with N<sub>2</sub>F<sub>2</sub> discussed later in the text. The SOF<sub>4</sub> formation results from the fluorination of SOF<sub>2</sub> by N<sub>2</sub>F<sub>2</sub> (described below). Its absence from the products after continued reaction and the lack of a complete material balance for the sulfur-containing species in this and in another experiment below may be explained by reaction with the metal fluorides present on the wall of the stainless steel reactor.<sup>11</sup> Although it was previously cited that N<sub>2</sub>F<sub>2</sub> undergoes free radical reactions, it was of interest to determine whether an electrophile, such as BF<sub>3</sub>, would catalyze the reaction between SO<sub>2</sub> and N<sub>2</sub>F<sub>2</sub> as it does the fluorination of ketonic double bonds by SF<sub>4</sub>.<sup>12</sup> However, in this case, BF<sub>3</sub> addition does not increase the rate of reaction or alter the nature or relative abundances of the products under the same conditions as in its absence. The existence of the FSO<sub>2</sub> radical and evidence that the reaction is not completely concerted is demonstrated by the quan-

titative formation of  $\text{FSO}_2\text{NF}_2$  at  $100^\circ$  by the addition of the radical trap,  $\text{N}_2\text{F}_4$ . This method of preparation of  $\text{FSO}_2\text{NF}_2$ , in addition to being quantitative, requires a lower temperature and a far shorter reaction time than those necessary in its preparation from  $\text{SO}_2$  and  $\text{N}_2\text{F}_4$ . The reactions of both  $\text{N}_2\text{F}_4$  and  $\text{N}_2\text{F}_2$  with  $\text{SO}_2$  appear to be initiated by fluorination.<sup>10</sup> The addition of  $\text{Br}_2$  to the  $\text{SO}_2$ - $\text{N}_2\text{F}_2$  reaction mixture results in the formation of  $\text{FSO}_2\text{Br}$  at  $100^\circ$ . The yield was 83% based on the  $\text{SO}_2$ . In the  $\text{SO}_2$ - $\text{N}_2\text{F}_2$  system it appears that  $\text{N}_2\text{F}_4$  and  $\text{Br}_2$  are nearly equally good radical traps.

With  $\text{SO}_3$  used as a substrate the type 2 reaction products  $\text{S}_3\text{O}_3\text{F}_2$ ,  $\text{S}_2\text{O}_5\text{F}_2$ ,  $\text{SO}_2\text{F}_2$ , and  $\text{N}_2\text{O}$  are formed. The nature and relative abundances of these products as well as the reaction rates are dependent upon the reactant ratios and type of reactor used. When excess  $\text{SO}_3$  is used, the major sulfur-containing product is  $\text{S}_2\text{O}_5\text{F}_2$  when either Pyrex or stainless steel is employed in the reactor. Trisulfuryl fluoride ( $\text{S}_3\text{O}_8\text{F}_2$ ) is also formed in Pyrex when the excess is large. Complete consumption of the  $\text{SO}_3$  is achieved in the presence of excess  $\text{N}_2\text{F}_2$  in Pyrex after 20 hr. at  $75^\circ$ , but is very nearly accomplished after 1 hr. at room temperature using stainless steel. The reaction using excess  $\text{N}_2\text{F}_2$  in metal at room temperature results in the initial formation of  $\text{S}_2\text{O}_5\text{F}_2$  and  $\text{N}_2\text{O}$  as the major products. Once being formed, the  $\text{S}_2\text{O}_5\text{F}_2$  may undergo further reaction with  $\text{N}_2\text{F}_2$  in metal at room temperature (but only to a very limited extent in Pyrex even at elevated temperatures) to yield  $\text{SO}_2\text{F}_2$  and  $\text{N}_2\text{O}$ . Reasonable material balances between  $\text{N}_2\text{O}$  and  $\text{SO}_2\text{F}_2$  and/or  $\text{S}_2\text{O}_5\text{F}_2$  were obtained.

To test whether the fluorosulfonate radical ( $\text{FSO}_3\cdot$ ) is an important species in the  $\text{SO}_3$ - $\text{N}_2\text{F}_2$  system as the  $\text{FSO}_2\cdot$  is in the  $\text{SO}_2$  case,  $\text{N}_2\text{F}_4$  was added. The addition resulted in the formation of only a negligible amount of  $\text{FSO}_2\text{ONF}_2$ <sup>13,14</sup> which, if present, was not found to react further. Hence, the fluorosulfonate radical is unimportant in this system. Since the rate of reaction is not the same in metal as it is in Pyrex, a reaction utilizing the reactor wall, perhaps in the presence of an adsorbed polymeric form of  $\text{SO}_3$ , is involved. Nevertheless, the formation of pyrosulfuryl and trisulfuryl fluorides by reaction of  $\text{SO}_3$  with fluorinating agents has precedent.<sup>15</sup>

Furthermore, *cis*- $\text{N}_2\text{F}_2$  does not react with either fluorosulfonate radical or the fluorosulfonate anion, since only decomposition of the diazine was noted under conditions employed when peroxydisulfuryl difluoride, fluorine fluorosulfonate (sources of the radical), and cesium fluorosulfonate were employed

as substrates. The latter was used to determine whether an ionic substrate would facilitate the formation of fluorine fluorosulfonate or type 2 reaction products and also because of its ease of being fluorinated<sup>16</sup> compared to the higher temperatures required for the other fluorosulfonate salts.<sup>17</sup>

The type 2 reaction between *cis*- $\text{N}_2\text{F}_2$  and  $\text{POF}_3$  yields  $\text{PF}_5$ ,  $\text{N}_2$ , and  $\text{O}_2$  in a ratio of very nearly 2:2:1. No  $\text{N}_2\text{O}$  was found in this case.

The reactions involving  $\text{SOF}_2$ ,  $\text{SF}_4$ , and  $\text{PF}_3$  each with  $\text{N}_2\text{F}_2$  represent reaction type 1 and may be expressed as follows.

Disulfur decafluoride is the major product formed by the reaction of *cis*- $\text{N}_2\text{F}_2$  with  $\text{SF}_4$  and, once formed, cannot be further fluorinated to  $\text{SF}_6$  on prolonged heating at  $100^\circ$  in the presence of a large excess of  $\text{N}_2\text{F}_2$ . The quantitative formation of  $\text{SF}_5\text{NF}_2$  when  $\text{N}_2\text{F}_4$  is added to the reaction mixture suggests the existence of the  $\text{SF}_6\cdot$ , and further fluorination by  $\text{N}_2\text{F}_2$  must take place prior to dimerization of the  $\text{SF}_5$  radical.

In contrast to the isomerization study of Colburn and co-workers<sup>2</sup> in a flow system at  $>225^\circ$ , it was found that the isomerization of *trans*- $\text{N}_2\text{F}_2$  to the *cis* isomer takes place below  $100^\circ$  nearly quantitatively in a static system. This isomerization is consistent with the heats of formation,<sup>18</sup>  $\Delta H_f^\circ = 16.4$  kcal. for *cis*- $\text{N}_2\text{F}_2$  and  $\Delta \bar{H}_f^\circ = 19.4$  kcal. for *trans*- $\text{N}_2\text{F}_2$ , which indicate that the *cis* isomer is the thermodynamically more stable. Yet the work of Colburn<sup>2</sup> and the fact that the reaction mixtures frequently contained several per cent *trans*- $\text{N}_2\text{F}_2$  (ca. 4% *trans*- $\text{N}_2\text{F}_2$  was present in the original  $\text{N}_2\text{F}_2$  samples used) indicate that the *cis* isomer is the chemically more reactive. *cis*- $\text{N}_2\text{F}_2$  is also the more labile with regard to yielding fluorinated products and  $\text{N}_2$  compared to the other binary N-F cognates. It is seen from this and other work that  $\text{N}_2\text{F}_2$  will attack stainless steel, Monel, and  $\text{SO}_2$  below  $100^\circ$ , whereas  $\text{N}_2\text{F}_4$  will undergo reaction with copper and  $\text{SO}_2$  above  $110^\circ$ .<sup>10</sup> The great inertness of  $\text{NF}_3$  is well known.<sup>19</sup>
