S Supporting Information

[ABSTRACT:](#page-6-0) The N-perfluoro-phenylated pyridyldiamine $H_2N_2^{~\mathrm{PFP}}N_{\mathrm{py}}$ (1) has been prepared by a palladium-catalyzed coupling of hexafluorobenzene and the diamine $(H_2NCH_2)_2C(CH_3)(2 C_5H_4N$) using the palladacycle trans-di(μ -acetato)bis[o -(di- o -tolylphosphino)benzyl]palladium-(II) as catalyst. Reactions of $H_2N_2^{\text{PFP}}N_{py}$ and $Zr(NMe_2)_4$ at room temperature or 90 °C led to the complexes $[(N^{\rm PFP}N_2^{\rm TFAP}N_{\rm py})\text{ZrF}(\text{N\acute{M}e}_2)]$ (2) and $[(N_2^{\rm TFAP}N_{\rm py})\text{ZrF}_2]$ (3) in which one or two dimethylamido groups replaced one or two ortho fluorine atoms of the pentafluorophenyl groups in the ligand. Reaction of Me₃SiX (X = Cl, I) with $[(N_2^T{}^{FAP}N_{py})ZrF_2](3)$ resulted in the formation of mixed halogenated complexes $[(N_2^T^{FAP}N_{py})ZrFI]$ (4) and $[(N_2^T^{FAP}N_{py})ZrFCl]$ (5)

in which the axially bound fluorido ligand is substituted. Reaction of $[(N_2^{TFAP}N_{py})ZrF_2]$ (3) with LiNHNPh₂ afforded the monohydrazido(1–) complex $\left[\frac{(N_{2}^{TFAP}N_{py})ZrF(NHNPh_{2})\right]$ (6) which was converted to the dimeric fluoro-potassium bridged hydrazinediido complex $[\rm{Zr(N_2^{TFAP}N_{py})FNNPh_2K}]_2$ (7) using KHMDS. The corresponding reaction with LiHMDS yielded the monomeric, donor free complex $[\mathrm{Zr}(\mathrm{N_2}^\mathrm{TFAP} \mathrm{N_{py}}) \mathrm{NNPh_2}]$ (8).

■ INTRODUCTION

The choice of the appropriate ancillary ligand is crucial for controlling the reactivity of a metal complex, in particular for the stabilization of reactive molecular fragments in the coordination sphere of a metal. This applies both to the development of new molecular catalysts and to the stabilization of reactive molecular fragments at the metal with the aim of gaining an understanding of the key active species and intermediates involved in catalytic reactions. For complexes of high-valent Lewis acidic early transition metals polydentate amido ligands have found widespread application in this context.¹ These not only shield and thus protect a well-defined sector of the coordination sphere but also predefine the structur[es](#page-7-0) of the "reactive sector". For the group 4 metal, diamido-donor ligands, $²$ in which the two negatively charged</sup> amido groups are combined with a neutral ligating unit, have proved to be particular[ly](#page-7-0) suited for the synthesis of complexes containing reactive $M=N$ bonds.³

In particular, the tridentate diamidopyridyl ligand $[N_2^{\text{PPP}}N_{\text{py}}]^{2-4}$ has given [ri](#page-7-0)se to a rich organometallic chemistry of group 4 metal imido and hydrazido complexes and their derivatives.^{[3](#page-7-0)} [T](#page-7-0)heir characteristic $M=N$ bond reactivity arises from the high polarity of this unit compared to the transition [m](#page-7-0)etals in middle of the d-block.⁵ In order to raise the Lewis acidity of the metal center we became interested in the possibility of preparing a diami[d](#page-7-0)opyridyl ligand of this type bearing pentafluorinated aryl groups. Given previous reports of the chemistry of N-fluoroarylated amido compounds,^{6−8} we expected reactive behavior which differed from that of the silylated and arylated diamidopyridyl ligands studied to d[a](#page-7-0)te.

In this work we report the synthesis of a pentafluorophenyl substituted $\left[N_{2}^{ \rm R} \rm N_{\rm py}\right]^{\tilde{2}-}$ ligand, its transformation upon reaction with $\left[\text{Zr(NMe}_2\right)_4\right]$, and the stepwise synthesis of hydrazinediido−zirconium complex. Interest in transition metal hydrazides has been due to the role they are thought to play in the stoichiometric and catalytic reduction of dinitrogen to ammonia. 9 In contrast to group 6 metals, the chemistry of group 4 metal hydrazinediido complexes has only been studied systemati[ca](#page-7-0)lly during the past decade and has given rise to a variety of stoichiometric and catalytic reaction patterns.^{10,11}

■ RE[SULT](#page-7-0)S AND DISCUSSION

Synthesis of the N-Pentafluorophenylated Protioligand H_2N_2 ^{PFP}N_{py} (1). Reaction of the diamine $(H_2NCH_2)_2C$ - CCH_3)(2-C₅H₄N)^{4b} ("H₂N₂^HN_{py}") and hexafluorobenzene in the presence of K_2CO_3 , as had been described previously by Schrock and co[-w](#page-7-0)orkers⁶ for the synthesis of a tris(Npentafluorophenylated) triaminoamine ligand, did not result in the formation of the t[ar](#page-7-0)get product. We therefore chose a Buchwald-Hartwig-type amination¹² to couple the aryl groups to the amine nitrogen atoms. Since the application of the most widely employed catalyst system, t[he](#page-7-0) combination of $Pd_2(dba)$ ₃ and racBINAP, proved not to be successful for the coupling of bromopentafluorobenzene and $(H_2NCH_2)_2C(CH_3)(2 C_5H_4N$),¹³ we tested the palladacycle trans-di(μ -acetato)bis[o-(di-o-tolylphosphino)benzyl]palladium(II) developed by Beller and Her[rm](#page-7-0)ann as precatalyst.¹⁴ Unexpectedly, the reaction of the diamine with bromopentafluorobenzene resulted in a product mixture because bot[h c](#page-7-0)arbon−bromine and carbon− fluorine bond activation occurred. When hexafluorobenzene was used instead, the desired protioligand $\mathrm{H_2N_2}^{\mathrm{PFP}}\mathrm{N_{py}}$ (1) was obtained in moderate yields (37%, Scheme 1), the major side

product being the mono pentafluorophenylated compound which could be recycled. This is a relatively rare case in which palladium-catalyzed C−N coupling is carried out with the aryl fluoride.¹⁵ The infrared spectra of the ligand $\mathrm{H_2N_2}^{\mathrm{PFP}}\mathrm{N_{py}}$ (1) as well as of the complexes discussed below display strong bands at $\nu = 800 \text{ cm}^{-1}$ $\nu = 800 \text{ cm}^{-1}$ $\nu = 800 \text{ cm}^{-1}$ to 1200 cm⁻¹, respectively, which are due to the C−F vibrations.¹⁶

Reaction of $H_2N_2^{\text{PFP}}N_{\text{py}}$ (1) with [Zr(NMe₂)₄]: Transfer of a Me₂N Grou[p t](#page-7-0)o the Ortho Position of the N-C₆F₅ **Rings.** The reaction of H_2N_2 ^{pFP} N_{py} (1) and $[Zr(NMe_2)_4]$ at room temperature afforded $[(N_2^{\text{P}'\text{PFP}}N_2^{\text{TFAP}}N_{\text{py}}) \text{ZrF}(\text{NMe}_2)]$ (2) as a yellow product in moderate yield. The ¹H and ¹⁹F NMR spectra indicate a nonsymmetrical complex, which is reflected in the observation of eight signals in the $19F$ NMR spectrum, seven in the aromatic region $(-145 \text{ ppm to } -180$ ppm) and one at +72 ppm, indicating a Zr-bound fluorine. This can be explained by the exchange of one of the four ortho fluorine atoms in the $N-C_6F_5$ rings by a dimethylamido group originating from the tetraamido zirconium starting material. This assignment is also supported by the ¹H NMR spectrum showing two separate singlet resonances for both methyl

groups of the coordinating dimethylamido unit and one singlet with an integral of six for the freely rotating dimethylamino group of the ligand. An exchange of this type was first reported by Schrock and co-workers for a related molybdenum $complex^{7a}$ and has been reported since for several other systems.7,8 Upon heating compound 2 to 90 °C for six days the formati[on](#page-7-0) of the difluorido complex $[(N_2^T F^{AP}N_{py})ZrF_2]$ 3 was observe[d \(](#page-7-0)Scheme 2). Complex 3 could also be prepared directly by adding ligand $\overline{H_2N_2}^{\text{PFP}}N_{\text{py}}$ (1) to $[\text{Zr}(\overline{\text{NMe}}_2)_4]$ followed by application of the same reaction conditions.

The ¹⁹F NMR spectrum of 3, displaying four signals in the aromatic region $(-150 \text{ ppm}$ to -177 ppm) as well as two singlets at 72.5 ppm and 102.5 ppm, was consistent with a C_{s} symmetric compound. An X-ray diffraction study revealed that two ortho fluorine atoms of the aryl rings had been replaced by dimethylamido groups. The molecular structure of 7-fold coordinated complex 3 is shown in Figure 1 along with selected bond lengths and angles.

The coordination geometry is best d[es](#page-2-0)cribed as distorted pentagonal bipyramidal with the amido nitrogen atoms and the dimethylamino groups of the N-aryl rings of the ancillary ligand

Figure 1. Molecular structure of complex 3. Selected bond lengths (Å) and angles (deg): $Zr(1)-N(1)/N(2) = 2.161(4)/2.152(4)$, $Zr(1)$ − $N(3) = 2.370(4), Zr(1)-N(4)/N(5) = 2.507(4)/2.529(4), Zr(1) F(1)/F(2) = 1.978(2)/1.957(3); F(2) - Zr(1) - F(1) = 102.6(1),$ F(2)−Zr(1)−N(3) = 177.2(1); N(4)−Zr(1)−N(5) = 135.6(1). Hydrogen atoms are omitted for clarity.

occupying four equatorial positions. The Zr(1)−N(1)/N(2) bonds are slightly longer (by 0.1−0.2 Å) than in related complexes with methyl-substituted aryl rings, $11g,13a$ which can be explained by the electron withdrawing effect of the fluorine substituents. The [py](#page-7-0)ridyl unit of the $N_2^{\text{TFAP}}N_{\text{py}}$ l[igan](#page-7-0)d and one fluorido ligand occupy the axial sites. The Zr−N(3) and the Zr−F bond lengths are in good agreement with those reported in literature. $7,$

Halide exchange in 3 was attempted by reaction with a slight excess of [trim](#page-7-0)ethylsilyl chloride or trimethylsilyl iodide (Scheme 2).¹⁷ In both cases only the mixed halogenated complexes were isolated in which the axially bonded fluorido ligand wa[s](#page-1-0) r[ep](#page-7-0)laced by the chloride or iodide. Even a large excess of the trimethylsilyl halide reagent did not result in the replacement of the equatorially bound fluorine atom as demonstrated by 19 F NMR spectroscopy (in both reactions only one signal between 90 ppm and 105 ppm corresponding to one zirconium bound fluorine atom was observed).

Single crystals suitable for X-ray diffraction were obtained from both complexes $[(N_2^{\text{TFAP}}N_{py})ZrFI]$ (4) and $[(N_2^T FAPN_{py})ZrFCl]$ (5) (see Supporting Information). The general structural features of both complexes are very similar, including C_s molecular symmet[ry. The molecular struct](#page-6-0)ure of $\left[\text{(N}_2^{\text{TFA} \bar{\text{P}}\text{N}}_{\text{py}}) \text{ZrFI}\right]$ (4) is shown in Figure 2. The zirconium is 7-fold coordinated by all nitrogen atoms of the facially coordinating diamidopyridyl ligand including the dimethylamino groups and both halogenides. The axial positions are occupied by the pyridine nitrogen of the ancillary ligand and the iodine atom (respectively the chlorine atom in 5), the "trans" angle differing significantly from linearity $(N(3)-Zr-I)$ 167.96(4)° and N(3)−Zr−Cl 169.06(4)°, respectively).

Synthesis and Structural Characterization of Hydrazido−Zirconium Complexes. The synthesis of hydrazinediido zirconium complexes stabilized by the diamidopyridyl ligand with amido N-aryl substituents has been achieved by addition of the corresponding hydrazine to a solution of bisamido complex $[(N_2^{\overline{X}yI}N_{py})Zr(NMe_2)_2]$ along with an excess of 4dimethylaminopyridine (DMAP).^{11h,i} Herein we describe the synthesis of hydrazinediido complexes containing the o -NMe₂ substituted N-fluoroarylated liga[nd](#page-7-0) described in this work. Reaction of the difluorido complex $[(N_2^{\text{TFAP}}N_{\text{py}})ZrF_2]$ (3) with 1 molar equiv of $LiNHNPh_2$ selectively led to one of the

Figure 2. Molecular structure of complex 4. Selected bond lengths (Å) and angles (deg): $Zr-N(1) = 2.1320(13)$, $Zr-N(3) = 2.3321(18)$, $Zr-N(4) = 2.5262(13), Zr-F(6) = 1.974(1), Zr-I = 2.8951(2);$ $F(6)$ −Zr−I = 110.75(4), N(3)−Zr−I = 167.96(4); N(4A)−Zr−N(4) $= 132.05(6)$. Hydrogen atoms are omitted for clarity.

possible isomers of the fluorohydrazido(1−) complex (6) (Scheme 3).

The ¹H NOESY NMR spectrum of 6 revealed cross relaxatio[n](#page-3-0) between the NH proton and the dimethylamino groups at the aryl substituents of the ligand. Furthermore no cross relaxation was observed between the NH proton and the hydrogen atoms of the pyridyl fragment of the ligand. This pattern indicates an axial coordination of the hydrazido(1−) fragment as depicted in Scheme 3.

Conversion of the hydrazido(1−) zirconium complex 6 to a hydrazinediido complex was [att](#page-3-0)empted by reaction with potassium hexamethyldisilazide in benzene. In view of the peripheral $Me₂N$ -donor functions in the supporting ligand, no additional neutral donor was added. Although the ¹H NMR spectrum indicated abstraction of the NH proton by the base, the ¹⁹F NMR spectrum of the isolated product 7 was consistent with the presence of a fluoride ligand bonded to Zr. An X-ray diffraction study revealed a dimeric structure in which the two zirconium complex units are formally KF adducts, in which the potassium cations associated with one of the hydrazido units are coordinated by the fluoraryl rings of the other complex fragment. The molecular structure of 7 is depicted in Figure 3, along with selected bond lengths and angles.

Coordination of each Zr atom is 7-fold by the diamidopyrid[yl](#page-4-0) ligand (including the dimethylamino groups), the hydrazinediido unit, and one fluorido atom. The molecular structure is therefore approximately pentagonal bipyramidal with the pyridyl fragment of the ligand and the near-linear hydrazinediido ligand occupying the axial positions. The Zr−N(6) and the N(6)-N(7) bond lengths are in good agreement with those found for other zirconium hydrazinediido complexes.¹¹ The two amido and the two dimethylamine nitrogen atoms as well as the remaining fluorido ligand are coordinated in t[he](#page-7-0) equatorial sites. The Zr–N(1)/N(2) bond lengths are longer [up to 0.2 Å] than in the halogenated complexes 3−5, indicating a weaker coordination of the ligand to the zirconium atom.

It did not prove possible to induce KF elimination from compound 7, in order to obtain the salt-free hydrazinediido complex, either by extended heating in toluene or K^+ Scheme 3. Synthesis of $\{N_2^{\text{TFAP}}N_{\text{py}}\}$ Zirconium Hydrazido Complexes

complexation with crown ethers or cryptants. However, reacting the hydrazido(1−) zirconium complex 6 with 1 equiv of lithium hexamethyldisilazide yielded the monomeric hydrazinediido complex 8 directly, the complete dehydrohalogenation being readily followed by $^1\mathrm{H}$ and $^{19}\mathrm{F}$ NMR spectroscopy. This may be due to the greater Lewis acidity of $Li⁺$ compared to $K⁺$ and the ability of the former to assist fluoride abstraction. Notably, an additional donor molecule like pyridine, hitherto employed in all isolated zirconium hydrazinediides, is not required.

The molecular structure of 8, as determined by single crystal X-ray diffraction, is depicted in Figure 4. The zirconium atom is 6-fold coordinated, with five coordination sites being occupied by the diamidopyridyl ligand inclu[di](#page-4-0)ng the dimethylamino groups and the remaining position by the hydrazinediido fragment. In contrast to previously reported systems featuring an arylated diamidopyridyl ligand, the hydrazinediido ligand occupies an equatorial site which we attribute to the geometric constraints imposed by the pentadentate amido-donor ligand.11j,k The Zr−N(6) bond length and the Zr−N(6)− N(7) angle are in good agreement with those of other hydra[zined](#page-7-0)iido zirconium complexes.¹⁸ The binding of the dimethylamino groups to the zirconium is stronger compared to the complexes discussed so far, as [re](#page-7-0)flected in the shorter $Zr(1)-N(4)/N(5)$ bonds, and may result from the lower coordination number of six $(Zr-N(4)/N(5))$ values: 3, $2.507(4)/2.529(4)$; 4, $2.526(1)$; 5, $2.481(1)$; 7, $2.522(1)/$ 2.565(2); 8, 2.436(1)/2.454(1)). Notably, one of the dimethylamino groups occupies an axial position, although the structural constraints of the ligand backbone lead to a considerable deviation of the "trans" angle N(4)−Zr−N(3).

■ CONCLUSION

In this work we have reported a new access to pentafluorophenyl substituted amine ligands using Pd coupling with hexafluorobenzene and $trans\text{-di}(\mu\text{-acetato})\text{bis}[\text{o-(di-o-}$ tolylphosphino)benzyl]palladium(II) as catalyst. Moreover, the resulting protioligand $H_2N_2^{PFP}N_{py}$ (1) was subsequently transformed to a potentially pentacoordinate supporting ligand

by reaction with $[\text{Zr}(\text{NMe}_2)_4]$. These additional donor functions proved to be important in the dehydrohalogenation of the monohydrazido(1−) complex 6 using LiHMDS giving the first donor free hydrazinediido zirconium complex. Further exploitation of this type of ancillary ligand is part of current and future work in our lab.

EXPERIMENTAL SECTION

General Experimental Procedures. All manipulations of air and moisture sensitive materials were carried out under an inert atmosphere of dry argon [argon 5.0] using standard Schlenk and glovebox techniques [glovebox: Unilab-2000, M. Braun]. Argon was dried over phosphorus pentoxide [Sicapent, Merck Chemicals] before use. Solvents were predried over molecular sieves and dried over Na/K alloy [pentane, diethyl ether] or K [toluene, THF, hexane, benzene] and distilled, or dried over activated alumina columns using a solvent purification system [M. Braun SPS 800] and stored over potassium or sodium mirrors [THF] in Teflon valve ampules. Deuterated solvents were purchased from Deutero GmbH, dried over K [benzene- d_6 , THF- d_8], vacuum distilled, and stored in Teflon valve ampules under argon. Samples for NMR spectroscopy were prepared under argon in 5 mm Wilmad tubes equipped with J. Young Teflon valves. NMR spectra were recorded on Bruker DRX200, Bruker Avance II 400, or Bruker Avance III 600 (with QNP-CryoProbe) NMR spectrometers. NMR spectra are quoted in ppm and were referenced internally relative to the residual protio-solvent $\rm [^1H]$ or solvent $\rm [^{13}C]$ resonances or externally to ¹⁵NH₃ [¹⁵N] and $C^{19}FCl_3$ [¹⁹F]. Where necessary, NMR assignments were confirmed by the use of two-dimensional H−¹H, ¹H−¹⁹F, and ¹H−¹³C correlation experiments. Infrared spectra of Nujol mulls were recorded on a Varian 3100 FT-IR. Elemental analyses were recorded by the analytical service of the Heidelberg Chemistry Department. The ligand precursor $(\text{H}_{2}\text{NCH}_{2})_{2}^{\circ}\text{C}(\text{CH}_{3})(2\text{-} \text{C}_{5}\text{H}_{4}\text{N})$ ₂(" $\text{H}_{2}\text{N}_{2}^{\text{-}H}\text{N}_{\text{py}}$ ") was prepared according to a published procedure.^{4b} Ph_2NNH_2 was prepared from the hydrochloride salt purchased from Acros, and purified by column chromatography (over silic[a,](#page-7-0) dichloromethane) prior to use. $LiNHNPh₂$ was synthesized according to the literature.¹⁹ All other reagents were obtained from commercial sources [Acros/Thermo Fischer, ABCR/Strem and Sigma-Aldrich] and used as re[cei](#page-7-0)ved unless explicitly stated. Trimethylsilyl reagents were degassed and stored in a glovebox.

Hydrogen atoms are omitted for clarity.

Preparation of Compounds. $H_2N_2^{PFP}N_{py}$ (1). Under an ensulter an ensulter an ensulter an ensulter an ensulter and the ensulter of a solution of *trans-diffu-caretatolbish of di-o*atmosphere of argon to a solution of trans-di(μ -acetato)bis[o -(di- o tolylphosphino)benzyl]palladium(II) (92 mg, 0.10 mmol, 2.0 mol %), cesium carbonate (8.15 g, 25 mmol, 5.0 equiv), and lithium bromide (0.17 g, 2.0 mmol, 0.4 equiv) in toluene (50 mL) were added the diamine MeC(2-C₅H₄N)(CH₂NH₂)₂ (0.83 g, 5.0 mmol, 1.0 equiv) and hexafluorobenzene (1.86 g, 10.0 mmol, 2.0 equiv), and the reaction mixture was stirred for 72 h under reflux. Subsequently, the solvent was removed under reduced pressure. The brown residue was redissolved in diethyl ether (50 mL) the resulting solution was washed with water $(2 \times 30 \text{ mL})$ and then with a saturated aqueous solution of NaCl $(2 \times 30 \text{ mL})$. The combined organic phases were dried over Na2SO4 and evaporated. The residue was purified by column chromatography on silica (pentane/diethyl ether 7:3, $R_f = 0.23$) to give the product as a light brown solid. Yield: 0.9 g (36%). The mono arylated ligand H_2N_2 ^{mono-PFP} N_{py} could be retrieved in the chromatographic workup and appeared after the fractions of 1 together with the unreacted starting material (characterization data given below). The mixture of both could be reused as educt for synthesis of the diarylated compound.

h₂] (215 mg, 0.26 mmol, 1.0 equiv) in benzene (5 mL) was added potassium hexamethyldisilazide (52 mg, 0.26 mmol, 1.0 equiv), and the reaction mixture was stirred for one day at room temperature. Subsequently, the solvent was removed under vacuum and the crude product was washed with pentane. The complex was obtained as a light brown powder. Yield: 80 mg (36%). ¹H NMR (C_6D_6 , 600.13 MHz, 296 K): δ = 1.18 (s, 6 H, 2*CH₃), 2.18 (s, 12 H, 2*N(CH₃)₂), 2.98 (d, $^2J_{HH}$ = 11.7 Hz, 4 H, 2*CHH), 3.08–3.17 (bs, 12 H, $2^*N(CH_3)_2$), 3.73–3.86 (m, 4 H, 2*CHH), 6.52 (d, $^3J_{\text{Ho-Phenyl/Hm-Phenyl}}$ $= 7.7$ Hz, 8H, 8^{*}H_{o-Phenyl}), 6.58 (t, ³J_{H5pyH6py/H4py} = 6.3 Hz 2 H, $2*H5_{\text{py}}$), 6.71 (t, ${}^{3}J_{\text{Hp-Phenyl/Hm-Phenyl}} = 7.4 \text{ Hz}$, 4 H, $4*H_{\text{p-Phenyl}}$), 6.89 $(d, \frac{3f}{H3py/H4py}$ = 8.0 Hz, 2 H, 2* $H3_{py}$), 6.98–7.05 (m, 10 H, $8*H_{\text{m-Phenyl}} + 2*H_{\text{3py}}$), 9.37–9.40 (m, 2H, 2*H6_{py}). ¹³C {¹H} NMR $(C_6D_6$, 150.91 MHz, 296 K): δ = 24.3 (CH₃), 44.9, 45.0, 45.1, 46.1, 46.1 (C-CH₃, N-(CH₃)₂), 63.7, 63.8 (CH₂), 118.1 (C_{o-Phenyl}), 119.8 $(C_{p\text{-Phenyl}})$, 120.1, 120.1 $(C_{p\text{y}}$, $C_{p\text{y}})$, 127.1 $(C\text{-N}(CH_3)_2)$, 128.6 $(C_{m\text{-}Phenyl})$ 136.9 $(C4_{\text{py}})$, 148.2, 148.4 (N- C_{Phipso}), 147.9 $(C6_{\text{py}})$, 163.0 $(C2_{\text{py}})$, $C_{\text{ar-F}}$ n.o., $C-N-C_{\text{Ph-Ligandipso}}$ n.o. ¹⁵N NMR $(C_6D_6, 40.52)$ MHz, 296 K): $\delta = 103.8$ (CH₂-N_{ar}), 163.8 (NNPh₂), 289.9 (N_{py}), NMe_2 n.o., $NNPh_2$ n.o. ¹⁹F NMR (C_6D_6 , 376.27 MHz, 296 K): $\delta =$

Table 1. Details of the Crystal Structure Determinations of 3·0.5benzene, 4·2benzene, 5, 7, and 8·0.5toluene

 -177.4 (td, ³J_{FpFm} = 21.4 Hz, ⁴J_{FpFo} = 9.4 Hz, 4 F, 4^{*}F_p), -164.0 (t, ³J_{FmFp,Fo} = 21.4 Hz, 4 F, 4^{*}F_m) -160.6 to -160.2 (m, 4 F, 4^{*}F_o), −148.8 to −148.5 (m, 4 F, $4*F_m$ benachbart zu C-NMe₂), −17.3 to −17.1 (m, 2 F, 2*Zr-F). IR (Nujol, NaCl, cm[−]¹): ν = 2917 vs, 2853 s, 1886 w, 1605 m, 1465 s, 1377 m, 1294 w, 1259 m, 1164 m, 1099 m, 1068 w, 1017 m, 995 m, 955 w, 843 m, 722 w, 674 w. Elemental analysis, $C_{74}H_{66}F_{18}K_2N_{14}Zr_2$: calcd C 50.67, H 3.79, N 11.18; found C 50.44, H 4.45, N 10.60.

FNHNPh₂] (75 mg, 0.1 mmol, 1.0 equiv) in benzene (2 mL) was ^{TFAP}N_{py})NNPh₂¹ (8). To a solution of $[\text{Zr}(\text{N}_2^{\text{TFAP}}\text{N}_{\text{py}})]$
b.1 (75 mg 0.1 mmol 1.0 equiv) in benzene (2 mL) was added lithium hexamethyldisilazide (19 mg, 0.1 mmol, 1.0 equiv), and the reaction mixture was stirred for one day at 60 °C. Subsequently, the solvent was removed under vacuum and the crude product was washed with pentane. The complex was obtained as a light brown powder. Yield: 20 mg (25%). ¹H NMR (C₆D₆, 600.13 MHz, 296 K): δ $= 1.01$ (s, 3H, CH₃), 2.58 (bs, 6H, N(CH₃)₂), 2.74 (bs, 6H, $N(CH_3)_2$), 3.38–3.65 (m, 4H, CH₂), 6.38 (t, ³J_{H5pyH6py/H4py} = 6.5 Hz, 1H, \overline{H}_{5py}), 6.73 (d, ${}^{3}J_{H3py/H4py}$ = 8.1 Hz, $1\overline{H}_{3py}$), 6.78 (t, ${}^{3}J_{Hp\text{-Phenyl}}$), 6.83–6.89 (m, 1H, ${}^{3}J_{Hp\text{-Phenyl}}$), 6.83–6.89 (m, 1H, H_{Py}), 7.13 (d, ${}^{3}J_{\text{HATHAr}}$ = 8.0 Hz, 4 H, $4{}^{*}H_{\text{m-Phenyl}}$), 7.31 (d, ${}^{3}J_{\text{J}}$ $J_{\text{Ho-Phenyl/Hmeta-Phenyl}} = 8.0 \text{ Hz}$, 4 H, 4^{*}H_{o-Phenyl}), 9.31 (d, ³J_{H6py/H5py} = 5.1 Hz, 1H, $H6_{py}$). ¹³C {¹H} NMR (C₆D₆, 150.91 MHz, 296 K): δ = 22.5 (CCH₃), 41.8, 42.2, 44.3, 44.5 (N-(CH₃)₂), 45.3 (C-CH₃), 62.0, 63.5 (CH₂), 117.5 (C_{o-Phenyl}), 119.0 (C_{p-Phenyl}), 119.2, 119.3 (C5_{py}, $(C3_{\text{py}})$, 126.8 $(C_{\text{m-Phenyl}})$, 137.3 $(C4_{\text{py}})$, 146.4 (C_{Phipso}) , 149.4 $(C6_{\text{py}})$, 161.7 (C2_{py}), C_{Ar−F} n.o., C_{ipso}-N n.o. ¹⁹F NMR (C₆D₆, 376.27 MHz, 296 K): $\delta = -160.6$ to -159.8 (m, 2F), -150.2 to -149.2 (m, 2F). IR (Nujol, NaCl, cm⁻¹): $\nu = 3273$ w, 2854 s, 2598 w, 1593 m, 1494 m, 1463 s, 1377 s, 1260 m, 1253 w, 1048 w, 976 m, 798 w, 722 m.

X-ray Crystal Structure Determinations. Crystal data and details of the structure determinations are listed in Table 1. Full shells of intensity data were collected at low temperature with a Bruker AXS Smart 1000 CCD diffractometer (Mo K α radiation, sealed tube, graphite monochromator) (3·0.5benzene) or an Agilent Technologies Supernova-E CCD diffractometer (Mo or Cu K α radiation, microfocus tube, multilayer mirror optics) (all others). Data were corrected for air and detector absorption and Lorentz and polarization effects;^{20,21} absorption by the crystal was treated with a semiempirical multiscan method,^{22−24} analytically,^{21,25} or numerically (Gaussian grid).²¹ [The](#page-7-0) structures were solved by direct methods with dual-space recycling²⁶ (3·0.5be[nzene](#page-7-0)), by the h[eavy](#page-7-0) atom method combined with st[ru](#page-7-0)cture expansion by direct methods applied to difference structure factors² (5) , or by the charge flip procedure²⁸ (all others) and refined by fu[ll](#page-7-0)matrix least-squares methods based on F^2 against all uniq[ue](#page-7-0) reflections.²⁹ All non-hydrogen ato[ms](#page-7-0) were given anisotropic displacement parameters. Hydrogen atoms were placed at calculated positions and refine[d w](#page-7-0)ith a riding model. When found necessary, disordered groups and/or solvent molecules where subjected to suitable geometry and adp restraints. Crystals of 3·0.5benzene were twinned; after detwinning (approximate twin fractions 0.76:0.24) refinement was carried out against all observations involving domain 1. In addition, due to severe disorder, electron density attributed to solvent of crystallization was removed from this structure with the BYPASS procedure,³⁰ as implemented in PLATON (SQUEEZE).³¹ Partial structure factors from the solvent masks were included in the refinemen[t a](#page-7-0)s separate contributions to F_{obs} .
