Received September 26, 1980

The kinetics of the anation reaction of  $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}]^{3+}$  by  $\text{H}_2\text{PO}_4^-/\text{H}_3\text{PO}_4$  in aqueous solution has been studied at 50, 60 and 70 °C and  $I = 1.0$  ( $\text{LiClO}_4$ ). The results indicate a rate law of the form  $k_{\text{obs}} = k_f[\text{H}_2\text{PO}_4^-]$ , with no (or small) contribution from  $\text{H}_3\text{PO}_4$ . No kinetic evidence of ion-pair formation has been observed in contrast to the analogous chromium(III) study. Values of  $k_f \times 10^5$  ( $\text{M}^{-1} \text{s}^{-1}$ ) are:  $4.50 \pm 0.07$ ,  $15.4 \pm 0.2$ , and  $53.9 \pm 0.8$  at 50, 60 and 70 °C respectively; the corresponding activation parameters are  $\Delta H^\ddagger = 26.9 \pm 0.8$  Kcal  $\text{mol}^{-1}$  and  $\Delta S^\ddagger = 4.2 \pm 2.4$  cal  $\text{K}^{-1} \text{mol}^{-1}$ .

### Introduction

The anation kinetics of  $[\text{Cr}(\text{NH}_3)_5\text{H}_2\text{O}]^{3+}$  by  $\text{H}_2\text{PO}_4^-/\text{H}_3\text{PO}_4$  has been reported recently [1]. On the other hand the analogous study of the reaction of  $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}]^{3+}$  with  $\text{H}_2\text{PO}_4^-/\text{H}_3\text{PO}_4$  has been only briefly investigated at 25 °C. Following our interest [1, 3, 4] in complexes containing phosphorus oxoanions we report a more complete study of the latter reaction at 50, 60 and 70 °C.

### Experimental

#### Materials

Aquopentaamminecobalt(III) perchlorate,  $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}](\text{ClO}_4)_3$  was prepared from carbonatopentaamminecobalt(III) nitrate,  $[\text{Co}(\text{NH}_3)_5\text{CO}_3] \cdot \text{NO}_3 \cdot \frac{1}{2}\text{H}_2\text{O}$  [5] and recrystallized twice [6]. The spectrum of aquo complex in 0.10 M  $\text{HClO}_4$ ,  $\lambda_{\text{max}}$  491 nm ( $\epsilon = 42.7 \text{ M}^{-1} \text{cm}^{-1}$ ),  $\lambda_{\text{min}}$  402 nm ( $\epsilon = 7.7 \text{ M}^{-1} \text{cm}^{-1}$ ),  $\lambda_{\text{max}}$  346 nm ( $\epsilon = 44.4 \text{ M}^{-1} \text{cm}^{-1}$ ) was in

agreement with literature values [7]. A solution of dihydrogenphosphatopentaamminecobalt(III) was made according to Schmidt and Taube [2]. Maxima and intensity ratio,  $\lambda_{\text{max}}$  515 nm,  $\lambda_{\text{max}}$  357 nm,  $\epsilon_1/\epsilon_2 = 0.70$  were also in accord with literature values [2]. The  $\text{LiClO}_4$  was prepared from  $\text{Li}_2\text{CO}_3$  and 60% analytical reagent  $\text{HClO}_4$  and recrystallized three times. A solution was made up and standardized by passing aliquots through Amberlite IR 120 (H) and titrating the eluted protons with sodium hydroxide. A solution of  $\text{LiH}_2\text{PO}_4$  was prepared by mixing equivalent amounts of solutions of  $\text{H}_3\text{PO}_4$  and  $\text{LiOH}$  and its molarity checked gravimetrically [8].

#### Kinetic Runs

The progress of the reaction was monitored at 530 nm where maximum difference between the extinction coefficient of aquo and phosphato complexes occurs, on a Beckman DU 2 spectrophotometer equipped with a thermospacer set connected to a Heto 01 E 623 thermostat ( $\pm 0.1$  °C). Kinetic runs were carried out in excess of total phosphate,  $[\text{PO}_4]_{\text{T}}$ , with regard to initial aquo-complex ( $9.87 \times 10^{-3} \text{ M}$ ). Values of  $k_{\text{obs}}$  were determined from the plots of  $-\ln(A_\infty - A_t)$  against time which were linear to more than 80% reaction. Final absorbance values ( $A_\infty$ ) were calculated from the spectrum of  $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{PO}_4]^{2+}$ . Successive scans (70 °C,  $[\text{PO}_4]_{\text{T}} = 0.3 \text{ M}$ ,  $[\text{H}^+] = 2.5 \times 10^{-3} \text{ M}$ ) on a Beckman UV 5230 spectrophotometer gave retention of isosbestic points at 477, 345 and 404 nm in agreement with those calculated (477, 346 and 403 nm). A run without added phosphate (60 °C,  $[\text{H}^+] = 0.001 \text{ M}$ ,  $I = 1.0$ ) gave no change in spectrum over a 5 h period. Values of  $[\text{H}^+]$ ,  $[\text{H}_2\text{PO}_4^-]$ , and  $[\text{H}_3\text{PO}_4]$  were calculated from added  $\text{HClO}_4$ ,  $\text{LiH}_2\text{PO}_4$ , and previously determined acidity constants of  $\text{H}_3\text{PO}_4$  in the same medium [1]. Errors quoted are standard deviations. Straight lines are least-squares fits with each point weighted as the inverse of its standard deviation.

## Results and Discussion

The system  $\text{H}_2\text{PO}_4^-/\text{H}_3\text{PO}_4^*$  reacts with  $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}]^{3+}$  to give  $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{PO}_4]^{2+}$  as the only product in agreement with the excellent reten-

\*A calculation using the three acidity constants of  $\text{H}_3\text{PO}_4$  showed that in the pH range used the only phosphorus containing species are  $\text{H}_3\text{PO}_4$  and  $\text{H}_2\text{PO}_4^-$ .

TABLE III. Values of  $k_f$  and Activation Parameters for the Anation of Aquopentaamminecobalt(III) by Phosphate.

| Temp. (°C) | $10^5 k_f, M^{-1}, s^{-1}$  |
|------------|---|
| 50.0       | $4.50 \pm 0.07$   |
| 60.0       | $15.4 \pm 0.2$  |
| 70.0       | $53.9 \pm 0.8$  |
|            | $\Delta H^\ddagger = 26.9 \pm 0.8 \text{ Kcal mol}^{-1}$              |
|            | $\Delta S^\ddagger = 4.2 \pm 2.4 \text{ cal K}^{-1} \text{ mol}^{-1}$ |

tion of calculated isobestic points (see Experimental). Values of  $k_{\text{obs}}$  as function of  $[\text{PO}_4]_{\text{T}}$  and  $[\text{H}^+]$  are given in Table I. Values of  $k_{\text{obs}}$  with same  $[\text{H}_2\text{PO}_4^-]$  do not show any clear increasing dependence on  $[\text{H}_3\text{PO}_4]$ , as can be seen from Table II for example, suggesting that  $\text{H}_3\text{PO}_4$  is non-reactive or much less so than  $\text{H}_2\text{PO}_4^-$ . Nonreactivity of a protonated anion in anation reactions has been previously reported by Swaddle *et al.* [9] in the system  $\text{N}_3^-/\text{HNO}_3 + [\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}]^{3+}$ .

The plots of  $k_{\text{obs}}$  against  $[\text{H}_2\text{PO}_4^-]$  (Fig. 1) and against  $[\text{PO}_4]_{\text{T}}$  (not shown) are linear without any curvature. The rate law has the form

TABLE IV. Second Order Rate Constants for the Anation of  $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}]^{3+}$  by Uninegative Anions at 60 °C.

| Anion                     | $10^4 k_f, M^{-1} s^{-1}$ | I                         | Ref.      |
|---------------------------|---------------------------|---------------------------|-----------|
| $\text{Cl}^-$             | 1.70                      | 2.0 ( $\text{LiClO}_4$ )  | 10        |
| $\text{AcO}^-$            | 2.5                       | 1.0 ( $\text{KNO}_3$ )    | 12        |
| $\text{N}_3^-$            | 2.24                      | 0.51 ( $\text{NaClO}_4$ ) | 9         |

| $\text{H}_2\text{PO}_4^-$ | 1.54                      | 1.0 ( $\text{LiClO}_4$ )  | This work |

Fig. 1. The dependence of  $k_{\text{obs}}$  on  $[\text{H}_2\text{PO}_4^-]$  for the anation of aquopentaamminecobalt(III) by phosphate.

$$k_{\text{obs}} = k_f[\text{H}_2\text{PO}_4^-]$$

Values of  $k_f$  and activation parameters are given in Table III. The value of  $k_f$  extrapolated to 25 °C ( $1.23 \times 10^{-6} M^{-1} s^{-1}$ ) is fairly similar to that found by Taube *et al.* ( $2.0 \times 10^{-6} M^{-1} s^{-1}$ ) in the equilibrium study of the same system at 25 °C [2].

Our results are in accordance with those of Kelm *et al.* [10]; they studied the anation reaction of  $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}]^{3+}$  and chloride sulphate (probably a mixture of  $\text{SO}_4^{2-}$  and  $\text{HSO}_4^-$ ) and did not find any curvature in the plots of  $k_{\text{obs}}$  against [anion] concluding that  $K_{\text{OS}}$  should be less than  $0.1 M^{-1}$ . All this does not agree with previously determined  $K_{\text{OS}}$  (25 °C) for  $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}]^{3+}/\text{X}^{n-}$  ( $\text{X}^{n-} = \text{H}_2\text{PO}_4^-, \text{SO}_4^{2-}$ ) of  $2.9 M^{-1}$  [2] and  $11.2 M^{-1}$  [11]

respectively; with such values some curvature should show up in the plots.

The analogous chromium system  $[\text{Cr}(\text{NH}_3)_5\text{H}_2\text{O}]^{3+} + \text{H}_2\text{PO}_4^-/\text{H}_3\text{PO}_4$  has been recently kinetically investigated under similar conditions [1]. It behaves differently since the plots of  $k_{\text{obs}}$  against  $[\text{PO}_4]_{\text{T}}$  show marked curvature. Equilibrium constants for outer-sphere complex formation

could be determined. One can speculate on how the variation of electronic configuration for the metallic centre ( $d^3$  to  $d^6$ ) can decrease the value of  $K_2$  from  $1.8 M^{-1}$  to less than *ca.*  $0.1 M^{-1}$ . Certainly the type of information obtained in these studies is invaluable in assessing the whole nature of outer sphere coordination which on the basis of the present studies is not solely determined by overall charge (and size) of reactants.

Finally it is of interest to compare our value of  $k_f$  for example at 60 °C,  $1.54 \times 10^{-4} M^{-1} s^{-1}$ , with those found by other authors for anation reactions of the same complex with different mononegative anions. Table IV indicates that our value of  $k_f$  is similar to those of the other mononegative anions, in accord with a mechanism with dissociative activation. The spread of rate constant is less than that now observed for  $[\text{Cr}(\text{NH}_3)_5\text{H}_2\text{O}]^{3+}$  which in turn is less than that observed for  $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$  which displays associative characteristics.
