Received December 15, 1978

*The successful isolation of  $\text{NiL}(\text{CO})_3$  and  $\text{NiL}_3(\text{CO})$  ( $\text{L} = \text{Me}_2\text{NPF}_2$ ) is reported. Boron trifluoride reacts with  $\text{NiL}_2(\text{CO})_2$  to yield  $\text{NiL}_2(\text{CO})_2 \cdot n\text{BF}_3$ , where  $n = 1.44$  at  $-128^\circ\text{C}$  and  $1.11$  at  $2^\circ\text{C}$ , and with  $\text{NiL}_4$  to yield  $\text{NiL}_4 \cdot n\text{BF}_3$ , where  $n = 2.6$  at  $-100^\circ\text{C}$ ,  $n = 1.78$  at  $-3^\circ\text{C}$  and  $n = 1.24$  at  $+20^\circ\text{C}$ . Nuclear magnetic resonance and infrared spectral data is presented which indicates that the  $\text{BF}_3$  coordinates to the nitrogen of the coordinated  $\text{Me}_2\text{NPF}_2$  ligands. Mass spectral data for the adducts has also been obtained.*

### Introduction

Among the more interesting of the trivalent phosphorus fluorides are the dialkyldiaminofluorophosphines. Such ligands offer two potential Lewis donor sites and indeed it has been demonstrated that  $\text{Me}_2\text{NEF}_2$  ( $\text{E} = \text{P}, \text{As}$ ) can bind to Lewis acids by either of the two donor sites, depending on the nature of the Lewis acid [1, 2].

Schmutzler [3] and Nixon and co-workers [4, 5] have prepared and studied the various dimethylaminodifluorophosphine complexes of Ni(0), but while the species  $\text{NiL}_4$  and  $\text{NiL}_2(\text{CO})_2$  ( $\text{L} = \text{Me}_2\text{NPF}_2$ ) have been isolated and characterised well, the  $\text{NiL}(\text{CO})_3$  and  $\text{NiL}_3(\text{CO})$  have only been obtained *in situ* and not been isolated. We here wish to report the isolation of these last two species and also the reactions of the  $\text{NiL}_4(\text{CO})_{4-n}$  complexes with boron trifluoride.

### Results and Discussion

Nickel tetracarbonyl and  $(\text{CH}_3)_2\text{NPF}_2$  react regardless of the order of addition or stoichiometry to produce  $\text{NiL}_2(\text{CO})_2$ . No matter how much L is added to  $\text{Ni}(\text{CO})_4$  only  $\text{NiL}_2(\text{CO})_2$  and (if enough L is added and the reaction heated)  $\text{NiL}_4$  are formed, and

it is impossible by using stoichiometric control of L to produce directly  $\text{NiL}(\text{CO})_3$  or  $\text{NiL}_3(\text{CO})$  [3]. If  $\text{NiL}_2(\text{CO})_2$  is stored for 4 to 8 weeks significant amounts (20 to 30%) of  $\text{NiL}(\text{CO})_3$  and  $\text{NiL}_3(\text{CO})$  are formed as a mixture with the original  $\text{NiL}_2(\text{CO})_2$ . This behaviour had been noticed by Nixon, Murray and Schmutzler [6] for  $\text{L} = \text{Me}_2\text{NPF}_2$ ,  $\text{Et}_2\text{NPF}_2$  and  $\text{C}_5\text{H}_{10}\text{NPF}_2$  and by Clark [7] for  $\text{L} = \text{PF}_3$ . The rate of rearrangement for  $\text{L} = \text{PF}_3$  is much faster [6] than for  $\text{L} =$  dialkyldiaminofluorophosphine. Clark [7] was able to separate  $\text{Ni}(\text{PF}_3)(\text{CO})_2$  and  $\text{Ni}(\text{PF}_3)_2(\text{CO})_2$  and  $\text{Ni}(\text{PF}_3)_3(\text{CO})$  by vapour phase chromatography, but attempts to separate and prove the independent existence of  $\text{NiL}_3(\text{CO})$  and  $\text{NiL}(\text{CO})_3$  where  $\text{L} = \text{Me}_2\text{NPF}_2$  have been unsuccessful prior to this work [3, 6, 8–10]. Nixon and Schmutzler [6, 8] have attributed this observed rearrangement to a dissociative process to form CO or L where the rate of dissociation is much slower in the case of the dialkyldiaminofluorophosphines as compared to  $\text{PF}_3$ . However, since the rearrangement is observed also *in vacuo* and no free L or CO is observed by us it is unlikely that the reaction proceeds via the dissociative mechanism suggested by Nixon and Schmutzler. The  $\text{NiL}(\text{CO})_3$ ,  $\text{NiL}_2(\text{CO})_2$  and  $\text{NiL}_3(\text{CO})$  are nicely separated by high pressure liquid chromatography which proves the independent existence of  $\text{NiL}_3(\text{CO})$  and  $\text{NiL}(\text{CO})_3$  as opposed to their existence as equilibrium species in solution which could not be isolated as independent species.

Our results from the n.m.r. measurements are similar to those reported by other workers [3, 11], viz:  $\text{NiL}_4$  ( $\delta_{\text{F}} + 38.9$ ,  $\delta_{\text{P}} - 167$ ,  $J_{\text{P-F}} 1104$ ),  $\text{NiL}_3(\text{CO})$  ( $\delta_{\text{F}} + 41.6$ ,  $J_{\text{P-F}} 1137$ ),  $\text{NiL}(\text{CO})_3$  ( $\delta_{\text{F}} + 44.8$ ,  $J_{\text{P-F}} 1157$ ),  $\text{NiL}_2(\text{CO})_2$  ( $\delta_{\text{F}} + 43.3$ ,  $\delta_{\text{P}} - 168.5$ ,  $J_{\text{P-F}} 1150$ ).

From the study done by Fleming and Parry [1] it is known the  $\text{BF}_3$  will add to the nitrogen of  $(\text{CH}_3)_2\text{NPF}_2$ . When  $(\text{CH}_3)_2\text{NPF}_2$  displaces two CO ligands in  $\text{Ni}(\text{CO})_4$  to form  $\text{NiL}_2(\text{CO})_2$  the  $(\text{CH}_3)_2\text{NPF}_2$  has been shown by Schmutzler [3] to coordinate to the

Ni through the phosphorus. There is now an extended  $\pi$  network from the nitrogen to the phosphorus ( $2p\pi \rightarrow 3d\pi$ ), backbonding from the Ni to the P ( $3d\pi_{\text{Ni}} \rightarrow 3d\pi_{\text{P}}$ ) and also backbonding from the Ni to the antibonding orbitals of CO. If  $\text{BF}_3$  coordinates to the nitrogen of  $\text{Ni}(\text{PF}_2\text{NMe}_2)_2(\text{CO})_2$  this should affect the whole extended  $\pi$  network, and cause noticeable changes in several of the stretching frequencies of the complex.

The  $\text{BF}_3$  uptake study described in the experimental section was done to determine how much  $\text{BF}_3$ ,  $n$ , the  $\text{NiL}_2(\text{CO})_2 \cdot n\text{BF}_3$  adduct contained over a large temperature range ( $-128$  to  $+3$  °C). At  $-128$  °C the excess  $\text{BF}_3$  has a vapour pressure of about 45 torr and with this vapour pressure it is possible to condense off into a  $-178$  °C trap all the uncomplexed  $\text{BF}_3$ . At  $-128$  °C,  $n = 1.44$ , indicating that more than one species is present in the reaction product [*i.e.*  $\text{NiL}_2(\text{CO})_2$ ,  $\text{NiL}_2(\text{CO})_2 \cdot n\text{BF}_3$  ( $n = 1, 2$ )]. Uptake of  $\text{BF}_3$  studies at temperatures lower than  $-128$  °C could not be carried out since it would be impossible experimentally to remove the excess uncomplexed  $\text{BF}_3$ . At  $+2$  °C the moles of  $\text{BF}_3$  present in the reaction product is 1.11.

If the  $\text{BF}_3$  coordinates through the oxygen of the CO in  $\text{NiL}_2(\text{CO})_2$  and not at all through the nitrogen of the L, minimal uptake of  $\text{BF}_3$  by  $\text{NiL}_4$  would be expected. If the  $\text{BF}_3$  coordinates with both the N and O sites of  $\text{NiL}_2(\text{CO})_2$ , a maximum value of  $n = 4$  would result from the uptake study. For this reason, a  $\text{BF}_3$  uptake study was performed with  $\text{NiL}_4$ .  $\text{NiL}_4$  has four nitrogen and no carbonyl donor sites available for coordination to  $\text{BF}_3$ . At  $-100$  °C  $n = 2.6$  for  $\text{NiL}_4 \cdot n\text{BF}_3$ . This indicates that the nitrogen of L in  $\text{NiL}_4$  readily takes up  $\text{BF}_3$  and is thus likely that the nitrogen of L also takes up  $\text{BF}_3$  in  $\text{NiL}_2(\text{CO})_2$ . Therefore at  $-100$  °C there must be either/or  $\text{NiL}_4 \cdot 3\text{BF}_3$  and  $\text{NiL}_4 \cdot 4\text{BF}_3$  present in the reaction mixture; of course, some  $\text{NiL}_4 \cdot \text{BF}_3$  and

$\text{NiL}_4 \cdot 2\text{BF}_3$  could also be present. Again, as was the case with  $\text{NiL}_2(\text{CO})_2$  it was impossible to force the uptake of  $\text{BF}_3$  to  $n = 4$  by lowering the reaction warm-up temperature much lower than  $-100$  °C since the vapour pressure of the excess uncomplexed  $\text{BF}_3$  gets too low to allow easy removal of the excess  $\text{BF}_3$ . The reaction of  $\text{BF}_3$  with either  $\text{NiL}_2(\text{CO})_2$  or  $\text{NiL}_4$  was shown by mass balance and infrared to be totally reversible indicating that no rearrangement had taken place:

For neat  $\text{NiL}_2(\text{CO})_2 \cdot n\text{BF}_3$  with slight  $\text{BF}_3$  overpressure the  $^{19}\text{F}$  n.m.r. shows two sets of gross doublets and a broad singlet. The first set of gross doublets has a chemical shift of  $+43.7$  ppm and a P-F coupling constant of 1150 Hz due to the ligand that has no  $\text{BF}_3$  coordinated to it and the second doublet with a shift of  $+45.8$  ppm and P-F coupling constant of 1184 Hz due to the ligand with  $\text{BF}_3$  coordinated to it. The very broad upfield singlet at  $+141.8$  is assigned to  $\text{BF}_3$  (probably due to overlapping peaks of coordinated and uncoordinated  $\text{BF}_3^*$ ). The  $^{31}\text{P}$  spectrum shows two overlapping triplets, one triplet has  $\delta_{\text{P}} -168.5$  ppm and  $J_{\text{P-F}} = 1150$  Hz due to the ligand without  $\text{BF}_3$  and the second triplet has  $\delta_{\text{P}} -166.3$  ppm and  $J_{\text{P-F}} = 1184$  Hz. In comparing  $^{19}\text{F}$  nmr data of Cavell [11] for  $\text{Me}_2\text{NPF}_2$  with the  $^{19}\text{F}$  nmr data of Fleming and Parry [1] for  $\text{Me}_2\text{NPF}_2 \cdot \text{BF}_3$  there is an increase in  $\delta_{\text{F}}$  (shifts to higher field) and  $J_{\text{P-F}}$  when  $\text{BF}_3$  coordinates to L. Also the  $^{31}\text{P}$

\*A referee has also pointed out that it is possible that the broadness could be due to the fact that fluorine is attached to boron which has a quadrupole.

TABLE I. Comparison of Major Assigned Infrared Bands.

Band Assignment	L <sup>a</sup>	$\text{NiL}_2(\text{CO})_2$	$\text{NiL}_2(\text{CO})_2 \cdot n\text{BF}_3$	$\text{NiL}_4$	$\text{NiL}_4 \cdot n\text{BF}_3$

<sup>a</sup>L =  $\text{Me}_2\text{NPF}_2$ . <sup>b</sup>dim. = greatly diminished in intensity compared to 1185. <sup>c</sup>B<sub>1</sub> bands overlapping, broadened and B<sub>1</sub> region shifted to higher wave number. <sup>d</sup>br = broadened.

shift data show a decrease in  $\delta_p$  when BF<sub>3</sub> coordinates to L. This same trend is noted for the coordination of BF<sub>3</sub> to NiL<sub>2</sub>(CO)<sub>2</sub>. Below 25 °C the NiL<sub>2</sub>(CO)<sub>2</sub>·nBF<sub>3</sub> adduct begins to form solid particles in solution thereby decreasing the concentration of adduct in solution. Also at lower temperatures the solubility of NiL<sub>2</sub>(CO)<sub>2</sub>·nBF<sub>3</sub> in NiL<sub>2</sub>(CO)<sub>2</sub> or CH<sub>2</sub>Cl<sub>2</sub> is insufficient to run the <sup>19</sup>F spectrum. Attempts to dissolve the solid adduct in acetone produced only NiL<sub>2</sub>(CO)<sub>2</sub> and (CH<sub>3</sub>)<sub>2</sub>C=O·BF<sub>3</sub>. The NiL<sub>4</sub>·nBF<sub>3</sub> adduct was insufficiently soluble in all solvents commonly used for <sup>19</sup>F spectra. Attempts to dissolve the NiL<sub>4</sub>·nBF<sub>3</sub> in acetone produced a solution of NiL<sub>4</sub> and (CH<sub>3</sub>)<sub>2</sub>C=O·BF<sub>3</sub> indicating that the oxygen of acetone is a better Lewis base than the nitrogen of the complex toward the hard Lewis acid BF<sub>3</sub>. If one adds BF<sub>3</sub> to a solution of either NiL<sub>2</sub>(CO)<sub>2</sub> or NiL<sub>4</sub> in CH<sub>2</sub>Cl<sub>2</sub>, solid BF<sub>3</sub> adduct product precipitates out without any detectable BF<sub>3</sub> adduct remaining in solution.

The major characteristic bands of the infrared spectra of Me<sub>2</sub>NPF<sub>2</sub> (L), NiL<sub>2</sub>(CO)<sub>2</sub>, NiL<sub>2</sub>(CO)<sub>2</sub>·nBF<sub>3</sub>, NiL<sub>4</sub> and NiL<sub>4</sub>·nBF<sub>3</sub> are listed in Table I. The tentative assignments of the new compounds made in this study have been based on those made by other workers [1, 3, 7, 12, 13]. Braunholtz [13] has shown for a large number of compounds of the type N-CH<sub>3</sub> an absorption band of medium to strong intensity is present between 2760 and 2820 cm<sup>-1</sup> due to the symmetrical stretch of a methyl group attached to a nitrogen whose lone pair is not involved in coordination. The presence or absence of this band in the 2760–2820 cm<sup>-1</sup> range provides a valuable diagnostic test for this group. For L, NiL<sub>2</sub>(CO)<sub>2</sub> and NiL<sub>4</sub>, the N-CH<sub>3</sub>  $\nu_s$  band is present indicating the nitrogen lone pair is not coordinated. The band is greatly diminished in intensity in NiL<sub>2</sub>(CO)<sub>2</sub>·nBF<sub>3</sub> and NiL<sub>4</sub>·nBF<sub>3</sub> indicating that some of the nitrogen lone pairs of these two compounds are forming adducts with BF<sub>3</sub> causing the band intensity to diminish. If n = 2 for NiL<sub>2</sub>(CO)<sub>2</sub>·nBF<sub>3</sub> or n = 4 for NiL<sub>4</sub>·nBF<sub>3</sub> the band would be expected to disappear completely. The band in the region 600–560 cm<sup>-1</sup> has been attributed to a B-N symmetrical stretch by using <sup>10</sup>B and <sup>11</sup>B isotope studies [1]. Bands appear in this region for NiL<sub>2</sub>(CO)<sub>2</sub>·BF<sub>3</sub> and NiL<sub>4</sub>·nBF<sub>3</sub> giving further evidence for the existence of a B-N bond in these three compounds. The A<sub>1</sub> C-O symmetrical stretch for NiL<sub>2</sub>(CO)<sub>2</sub> is at 2060 cm<sup>-1</sup>. When BF<sub>3</sub> is added to NiL<sub>2</sub>(CO)<sub>2</sub> two new A<sub>1</sub> bands appear at 2070 and 2098 cm<sup>-1</sup> tentatively assigned to NiL<sub>2</sub>(CO)<sub>2</sub>·nBF<sub>3</sub> where n = 1 and 2 respectively. The B<sub>1</sub> C-O stretching region undergoes a similar shift to higher frequency but these bands overlap making assignment impossible. The shift to higher frequency of the two new A<sub>1</sub> bands indicates that as the BF<sub>3</sub> coordinates to the nitrogen of NiL<sub>2</sub>(CO)<sub>2</sub>, the nitrogen lone pair is no longer available to

TABLE II. Infrared Carbonyl Stretching Frequencies and Assignments for NiL<sub>4-n</sub>(CO)<sub>n</sub> (n = 1, 2, 3).

	$\nu_{C-O}$ cm <sup>-1</sup>	Assignment
NiL(CO) <sub>3</sub>	2102 m	A <sub>1</sub>

	2050 w, shoulder	Ni(C <sup>13</sup> O)(C <sup>12</sup> O)L <sub>2</sub>
	2009 s	B <sub>1</sub>
	1975 w	Ni(C <sup>13</sup> O)(C <sup>12</sup> O)L <sub>2</sub>
NiL <sub>3</sub> (CO)	2018 s	A <sub>1</sub>
	1970 w	Ni(C <sup>13</sup> O)L <sub>3</sub>

s = strong; m = medium; w = weak; sh = shoulder.

\*Has some E-band splitting due to low symmetry of L.

undergo 2p → 3d bonding with the empty d orbitals on phosphorus. This makes the phosphorus a better acceptor from the nickel which causes the nickel to donate more of its d electrons into the empty d orbitals on phosphorus at the expense of donating some of these electrons to the antibonding orbitals of the carbonyl. Since fewer electrons are now being donated to the antibonding orbitals of the carbonyl, the carbonyl bond order increases and this is reflected in the shift to higher A<sub>1</sub> carbonyl stretching frequencies for NiL<sub>2</sub>(CO)<sub>2</sub>·nBF<sub>3</sub>.

The P-F stretching frequencies ( $\nu_a$  and  $\nu_s$  respectively) are shifted to higher frequency in going from L to L·BF<sub>3</sub>. This indicates a strengthening of the P-F bond in L·BF<sub>3</sub>. When BF<sub>3</sub> coordinates to the nitrogen, the nitrogen can no longer 2p $\pi$  → 3d $\pi$  bond to the phosphorus. This causes the phosphorus to take a greater share of the electrons in the P-F bond which makes the bond stronger and more covalent which is reflected in the shift of the P-F stretching bands to higher frequency. The same trend is noted in going from NiL<sub>2</sub>(CO)<sub>2</sub> to NiL<sub>2</sub>(CO)<sub>2</sub>·nBF<sub>3</sub> which can be explained in the same terms (although the magnitude of the shift is slightly less for the NiL<sub>2</sub>(CO)<sub>2</sub> case compared to L). One sees an opposite trend in a shift to low frequencies for the P-F stretch in going from NiL<sub>4</sub> to NiL<sub>4</sub>·nBF<sub>3</sub>. The reason for this is not clear. Perhaps this partly reflects a steric effect in NiL<sub>4</sub> which is not seen in NiL<sub>2</sub>(CO)<sub>2</sub> or L.

Table II lists the infrared carbonyl stretching frequencies for NiL(CO)<sub>3</sub>, NiL<sub>2</sub>(CO)<sub>2</sub> and NiL<sub>3</sub>(CO) and assignments are made by comparison with those of Loutelier and Bigorne [12] for the corresponding series of PF<sub>3</sub> compounds. By comparing the A<sub>1</sub> mode which is in all three, one sees a decrease in  $\nu_{A_1}$  from NiL(CO)<sub>3</sub> to NiL<sub>3</sub>(CO) indicating that as more Me<sub>2</sub>NPF<sub>2</sub> replace CO, the coordinating phosphorus is a poorer  $\pi$  acceptor of electrons from Ni and consequently as poorer  $\pi$  acceptor L's are added, more

TABLE III. Mass Spectrum of  $\text{NiL}_2(\text{CO})_2 \cdot n\text{BF}_3$  (E.I. Mode).

m/e	Ion	Relative Intensity
476	$\text{NiL}_2(\text{CO})_2 \cdot 2\text{BF}_3^+$	16
408	$\text{NiL}_2(\text{CO})_2 \cdot \text{BF}_3^+$	6
380	$\text{NiL}_2(\text{CO}) \cdot \text{BF}_3^+$	12
340	$\text{NiL}_2(\text{CO})_2^+$	5
312	$\text{NiL}_2(\text{CO})^+$	2
284	$\text{NiL}_2^+$	2
199	$\text{NiL}(\text{CO})^+$	3
181	$\text{L} \cdot \text{BF}_3^+$	8
171	$\text{NiL}(\text{CO})^+$	2
113	$\text{L}^+$	100

TABLE IV. Mass Spectrum of  $\text{NiL}_4 \cdot n\text{BF}_3$  (E.I. Mode).

m/e	Ion	Relative Intensity
578	$\text{NiL}_4 \cdot \text{BF}_3^+$	2
510	$\text{NiL}_4^+$	20
465	$\text{NiL}_3 \cdot \text{BF}_3^+$	18
397	$\text{NiL}_3^+$	60
352	$\text{NiL}_2 \cdot \text{BF}_3^+$	7
284	$\text{NiL}_2^+$	70

171	$\text{NiL}^+$	30
113	$\text{L}^+$	100

Ni d-electrons are being donated into the antibonding orbitals of the C–O as one goes from the  $\text{L}_1$  to the  $\text{L}_3$ . The increased donation of electrons by Ni into C–O antibonding orbitals causes a decrease in the C–O bond order and hence a shift to lower frequencies of the  $\text{A}_1$  C–O stretch as one goes from  $\text{L}_1$  to  $\text{L}_3$ . The E mode has some splitting due to the low symmetry of L.

The complete mass spectrum of  $\text{NiL}_2(\text{CO})_2 \cdot n\text{BF}_3$  run in the E.I. mode is listed in Table III. The mass spectrum shows evidence for the existence of the species  $\text{NiL}_2(\text{CO})_2 \cdot 2\text{BF}_3$  and  $\text{NiL}_2(\text{CO})_2 \cdot \text{BF}_3$ . It is interesting to note that the preferred breakdown pattern of the adducts is the loss of  $\text{L} \cdot \text{BF}_3$  from the  $\text{NiL}_2(\text{CO}) \cdot \text{BF}_3^+$  ion to form  $\text{NiL}(\text{CO})^+$  instead of the loss of CO to form  $\text{NiL}_2 \cdot \text{BF}_3^+$ . There is no evidence for the loss of L when an  $\text{L} \cdot \text{BF}_3$  group is present also. Another mass spectrum run on an aged sample of  $\text{NiL}_2(\text{CO})_2$  showed the presence of the species  $\text{NiL}_3(\text{CO})^+$  m/e = 425 and  $\text{NiL}(\text{CO})_3^+$  m/e = 225.  $\text{BF}_3$  addition to this mixed aged sample showed presence of  $\text{NiL}_3(\text{CO})_3 \cdot 2\text{BF}_3^+$  m/e = 561,  $\text{NiL}_3(\text{CO}) \cdot \text{BF}_3$  m/e = 493 and  $\text{NiL}(\text{CO})_3 \cdot \text{BF}_3$  m/e = 323.

The complete mass spectrum of  $\text{NiL}_4 \cdot n\text{BF}_3$  run in the E.I. mode is listed in Table IV. The mass spectrum shows evidence for the existence of  $\text{NiL}_4 \cdot \text{BF}_3$ . It is known from the  $\text{BF}_3$  uptake studies that either/or  $\text{NiL}_4 \cdot 4\text{BF}_3$  and  $\text{NiL}_4 \cdot 3\text{BF}_3$  may be present. The relative intensity of m/e 578 ( $\text{NiL}_4 \cdot \text{BF}_3^+$ ) is only 2%.  $\text{NiL}_4 \cdot 4\text{BF}_3^+$  would have an m/e = 782 and  $\text{NiL}_4 \cdot 3\text{BF}_3^+$  would have an m/e = 714. The high mass of these two species would cause a low volatility under the conditions that the spectrum was run and consequently were not seen as  $\text{NiL}_4 \cdot 4\text{BF}_3$  or  $\text{NiL}_4 \cdot 3\text{BF}_3$ , but  $\text{BF}_3$  was pumped off until  $\text{NiL}_4 \cdot \text{BF}_3$  was present which was sufficiently volatile at  $10^{-7}$  torr to be seen.

## Experimental

### Starting Materials

Nickel tetracarbonyl was obtained from Strem Chemical Co. in a 100 g gas cylinder pressurized with carbon monoxide to 15 psi. The  $\text{Ni}(\text{CO})_4$  was frozen at  $-178^\circ\text{C}$  (liquid in trap) and the remaining CO gas was pumped off prior to the initial use.  $\text{PF}_3$  was obtained from Ozark-Mahoning. Commercial  $\text{BF}_3$  and  $(\text{CH}_3)_2\text{NH}$  were obtained from Matheson and were shown by gas phase infrared to be essentially pure.

### Dimethylaminodifluorophosphine

Using a modified version of Cavell's procedure [11], gaseous dimethylamine was bled into a previously evacuated 5000-ml bulb on the vacuum line to a pressure of 500 torr and was then closed off.  $\text{PF}_3$  was added to the rest of the vacuum line at a pressure of 700 torr. The closed off stop cock to the 5000-ml bulb was opened and this over-pressure of  $\text{PF}_3$  was then bled into the bulb containing the dimethylamine while the line pressure was maintained at a pressure of about 700 torr by the continued addition of  $\text{PF}_3$  to the line. The  $\text{PF}_3$  addition was periodically stopped to check for continued reaction via pressure drop and was discontinued after no pressure drop was noted after stopping the addition of  $\text{PF}_3$  to the line. This procedure assured that all the dimethylamine had reacted and that there was an excess of  $\text{PF}_3$  present since the vapour pressure of the product is less than 300 torr at ambient temperature [12].

The volatile product,  $(\text{CH}_3)_2\text{NPF}_2$ , was separated from the excess  $\text{PF}_3$  by high vacuum, low temperature fractionation through traps cooled to  $-45$ ,  $-78$ ,  $-178^\circ\text{C}$  consecutively. The  $\text{PF}_3$  passes through to the  $-178^\circ\text{C}$  trap while the  $(\text{CH}_3)_2\text{NPF}_2$  stops in the  $-45^\circ$  and  $-78^\circ\text{C}$  traps. The  $(\text{CH}_3)_2\text{NPF}_2$  was identified and checked for purity by comparing its infrared with that of Cavell's [11].

This modification of Cavell's method has the advantage of allowing one to prepare large quantities

of the dimethylaminodifluorophosphine at one time.

#### *Ni(Me<sub>2</sub>NPF<sub>2</sub>)<sub>4</sub> and Ni(Me<sub>2</sub>NPF<sub>2</sub>)<sub>2</sub>(CO)<sub>2</sub>*

These were prepared by standard literature methods [3, 4].

#### *Isolation of NiL<sub>3</sub>(CO) and NiL(CO)<sub>3</sub>*

A sample of a mixture of NiL<sub>n</sub>(CO)<sub>4-n</sub> (n = 1, 2, 3) was dissolved in spectral grade hexane to make an approximately 20% (by volume) solution. The hexane solution was purged with dry nitrogen. The liquid chromatograms were carried out on a Waters Associate L.C. run at 1600 psi and at a flow rate of 1.5 ml/min. Three peaks were detected using the refractive index detector. The first corresponded to the NiL(CO)<sub>3</sub>, the second to NiL<sub>2</sub>(CO)<sub>2</sub> and the third to NiL<sub>3</sub>(CO). The identification was made by <sup>19</sup>F nmr. The chromatogram peaks were well separated and the liquid chromatogram output was collected in N<sub>2</sub> filled polyethylene bottles as each peak was seen on the refractive index detector. This process was repeated about 8 times with all l.c. outputs corresponding to peak 1, peak 2 and peak 3 being respectively combined. The solutions were concentrated by evaporation of some of the hexane solvent by bubbling dry N<sub>2</sub> through the solution until the final volume was about 5 ml. Infrared spectra were made with the concentrated solutions of the samples using a 0.1 mm KBr liquid infrared cell. The spectra were recorded on a very slow scan time using an ultra fine tip pen and were calibrated using the sharp 1601.4 cm<sup>-1</sup> band of polystyrene file.

The major infrared peaks are tabulated and assigned in the Results and Discussion.

The compound NiL(CO)<sub>3</sub> was volatile and had significant vapor pressure at room temperature. NiL<sub>2</sub>(CO)<sub>2</sub> and NiL<sub>3</sub>(CO) had essentially no vapor pressure at room temperature and were essentially non-volatile at a 10<sup>-2</sup> torr pressure at room temperature.

#### *Reaction of NiL<sub>2</sub>(CO)<sub>2</sub> with BF<sub>3</sub>*

A 75 ml Fischer-Porter reactor was evacuated and tared. The reactor was then opened in a dry N<sub>2</sub> filled glove bag. Freshly prepared NiL<sub>2</sub>(CO)<sub>2</sub> (L = Me<sub>2</sub>NPF<sub>2</sub>) was added, the reactor was again evacuated and it was then determined that 5.00 × 10<sup>-3</sup> mol of NiL<sub>2</sub>(CO)<sub>2</sub> had been added. The reactor and contents were then cooled to -178 °C and BF<sub>3</sub> (5.0 × 10<sup>-2</sup> mol) was condensed into the reactor and allowed to interact with the NiL<sub>2</sub>(CO)<sub>2</sub> for 1 hr. The reactor and contents were then allowed to warm to -128 °C and allowed to interact for an additional hour. The excess, uncomplexed BF<sub>3</sub> was slowly condensed off at -128 °C until no noticeable additional BF<sub>3</sub> pressure was given off under a static vacuum of <1 torr for a period of 15 minutes. The Fischer-Porter

reactor containing the NiL<sub>2</sub>(CO)<sub>2</sub>·nBF<sub>3</sub> adduct was then sealed and allowed to warm to room temperature and the mol, n, of BF<sub>3</sub> added was determined by mass gain: n = 1.44 at -128 °C. The above procedure was repeated at -80 °C and +2 °C in place of -128 °C and it was determined by mass gain that n = 1.2 at -80 °C and n = 1.11 at +2 °C. The BF<sub>3</sub> addition could be totally reversed by pumping on the adduct overnight at room temperature. The reversibility was shown by both mass balance and identical infrared spectra before the BF<sub>3</sub> was added and after the BF<sub>3</sub> was all pumped off. The various above BF<sub>3</sub> adducts are solids which show in the infrared the characteristic B-N stretching vibration at 610 cm<sup>-1</sup> (B-N stretch region 560-660 cm<sup>-1</sup> [1]).

The <sup>19</sup>F nmr spectrum run neat at room temperature with a slight overpressure of BF<sub>3</sub> consisted of two doublets and a broad singlet, one doublet was centered at 43.7 ppm (J<sub>p-f</sub> = 1150 cps) and the other was centered at 45.8 ppm (J<sub>p-f</sub> = 1184 cps). The very broad singlet was at 141.8 ppm. Attempts to run low temperature nmr either neat or in CH<sub>2</sub>Cl<sub>2</sub> proved unsuccessful due to the precipitation of solid adduct which made meaningful resolution impossible.

The <sup>31</sup>P nmr spectrum run on this same sample showed basically two overlapping triplets, one centered at -168.5 ppm (J<sub>p-f</sub> = 1150 cps) and the other centered at about -166.3 ppm (J<sub>p-f</sub> = 1184 cps).

#### *Reaction of NiL<sub>4</sub> with BF<sub>3</sub>*

A 75 ml Fischer-Porter reactor was evacuated and tared. The reactor was then placed in a dry N<sub>2</sub>-filled glove bag. A concentrated solution of freshly filtered (to remove any insoluble oxidation product) NiL<sub>4</sub> in CH<sub>2</sub>Cl<sub>2</sub> was added to the reactor. The CH<sub>2</sub>Cl<sub>2</sub> solvent was slowly pumped off on the vacuum line leaving behind the NiL<sub>4</sub> (2.59 × 10<sup>-3</sup> mol). The evacuated reactor and contents were then cooled to -178 °C and BF<sub>3</sub> (5.0 × 10<sup>-3</sup> mol) was condensed into the reactor and allowed to interact with the NiL<sub>4</sub> for 1 hr. The reactor and contents were then allowed to warm to -100 °C and were allowed to interact for an additional hour. The excess, uncomplexed BF<sub>3</sub> was slowly condensed off at -100 °C until no noticeable additional BF<sub>3</sub> pressure was given off under a static vacuum of <1 torr for a period of 15 min. The Fischer-Porter reactor containing the NiL<sub>4</sub>·nBF<sub>3</sub> adduct was then sealed and allowed to warm to room temperature and the mol, n, of BF<sub>3</sub> added were determined by mass gain: n = 1.78 at -3° and n = 1.24 at +20 °C. The BF<sub>3</sub> addition could be totally reversed by pumping on the adduct overnight at room temperature. The reversibility was shown by both mass balance and identical infrared spectra before the BF<sub>3</sub> was added and after the BF<sub>3</sub> was all pumped off. The n = 2.6 adduct is a solid, the n =

1.78 and  $n = 1.24$  adducts are very viscous oils having almost the consistency of glass slightly above its softening temperature.
