Exciplex Formation between Silver Ions and the Lowest MLCT Excited State of the Tris(Bipyrazine)ruthenium(II) Cation

A. B. P. LEVER*, PENNY SEYMOUR and PAMELA R. AUBURN *Department of Chemistry, York University, North York, Toronto, Ont., M3J lP3, Canada* (Received July 30,1987)

The lowest excited MLCT state of the [Ru- $(bpz)_{3}$ ²⁺ cation (1) is shown to react with silver ion in aqueous or acetonitrile solution to form exciplexes with up to six silver ions per excited cation. Lifetime, wavelength data are presented as a function of the $[Ag]/[Ru]$ ratio. An excited state (reductive quenching) potential of 1.55 V is derived from quenching by a range of methoxybenzenes. Data for quenching by metal ions are also presented. There is no ground state interaction between **1** and silver ions.

Introduction

The $\left[\text{Ru(bpz)}_3\right]^{2+}$ ion (1) (bpz = 2,2'-bipyrazine) has been the subject of extensive investigation $[1-18]$ because of its utility as a photocatalyst and its complementarity to the $[Ru(bpy)_3]^{2+}$ ion (2) (bpy = 2,2'-bipyridine) [191. A characteristic of **1,** not shared by 2, is the presence of six peripheral nitrogen atoms each with a lone pair of electrons capable of donation to a Lewis acid [20]. Thus, ground state **1,** and related bipyrazine complexes, have been observed to coordinate with protons [14, 201, pentacyanoferrate(II), [5], boron trifluoride [20], and pentaammineruthenium $(II)/(III)$ [21]. During a recent study of the luminescence quenching of **1,** it was observed that silver ions did not quench the lowest excited metal to ligand charge transfer (MLCT) transition while many organic quenchers and other metal ions were effective [8]. By analogy with the quenching behaviour of $2 \lfloor 19 \rfloor$, this was an unexpected result. However Kobayashi and co-workers have briefly reported reaction of silver ions with the peripheral nitrogen atoms of the $\left[\text{Ru(bpy)}_2\text{(bpz)}\right]^2$ ⁺ cation [22]. A ruthenium tris(bipyrazine) excited state cation with six silver atoms bound to the peripheral nitrogen atoms would possess a formal charge of 8+ and would thereby be expected to be a much stronger excited state oxidant than **1** itself, and con-

Abstract **Abstract ceivably** strong enough to oxidize water directly, providing a good rationale for the study.

Experimental

Materials

 $Ru(bpz)_{3}(PF_6)_{2}$ was synthesized and purified as previously described $[17]$. AgNO₃, anhydrous AgClO₄, KNO_3 , $Cu(NO_3)_2.6H_2O$ and $Ni(NO_3)_2.6H_2O$ were analytical grade. A loan of $RuCl₃·3H₂O$ from Johnson Matthey is gratefully acknowledged. The series of methoxybenzenes was used without further purification. Aqueous solutions were prepared with water which had been doubly distilled from $KMnO₄$ and passed through both mixed bed and organic water purification cartridges (Barnstead). Acetonitrile was Aldrich Gold Label. Tetrabutylammonium perchlorate (Eastman) (TBAP) was recrystallized from ethanol and vacuum dried.

Luminescent Emission Measurements

Emission spectra were recorded with a Varian SF-330 spectrofluorimeter. The exciting wavelength was 423 nm. In both solvent systems, the concentration of $\left[\text{Ru(bpz)}_3\right]^{2+}$ was about 1.6×10^{-5} M. Solutions were prepared in 0.1 M $KNO₃$ or 0.01 M TBAP in $CH₃CN$ to maintain constant ionic strength. In both systems, the PF_6^- salt of the ruthenium complex was used to eliminate possible formation of AgCl. AgNO₃ and AgClO₄ were used in aqueous and acetonitrile solution respectively.

The methodology of obtaining the luminescence measurements was the same as reported previously [8], and emission intensities were corrected for the inner filter effect. Quencher concentrations were in the range of $0.01-0.1$ M for the methoxybenzenes, and 0.01-0.5 M for the inorganic metal salts.

Lifetime measurements were carried out using a York University constructed 0.5 MW pulsed nitrogen laser and a Princeton Applied Research (PARC) Model 162 boxcar averager with Model 165 and 166 gated integrators. Data were plotted on a X-Y recorder and lifetimes calculated by manual transfer

^{*}Author to whom correspondence should be addressed.

Other Measurements

Absorption spectra were recorded on a Perkin-Elmer Hitachi Model 340 microprocessor spectrometer. ¹H NMR spectra were recorded in D_2O with a Bruker Aspect 300 spectrometer. Chemical shifts and scale are reported downfield from DSS. FT-IR spectra were recorded as KBr discs using a Nicolet SX20 spectrometer.

Results

(i) Ground State Studies

The addition of silver ion, as $AgClO₄$ or $AgNO₃$, to aqueous solutions of **1** in O-1500:1 molar ratio, and in the presence of 0.1 M or 0.01 M KNO₃ causes no change in the electronic absorption (visible or ultra-violet region) spectrum of **1.** Moreover the 'H NMR spectrum of **1** in water is unperturbed by the addition of excess silver ion. In another experiment, $[Ru(bpz)_3](ClO₄)_2$ and excess AgClO₄ were heated in water for 3 h and then evaporated to dryness. The FT-IR spectrum of the resulting solid was indistinguishable from that of a physical mixture of the reactants. **400 500 600 700**

(ii) Excited State Studies

(a) Wavelength dependence. When excited at 450 nm into the allowed lowest singlet-singlet MLCT transition, complex **1** emits near 600 nm from the

³MLCT state (1^{*}) associated with the Ru(t_{2g})⁶ \longrightarrow $\pi^*(1)$ (bpz) transition (Fig. 1) [17]. The wavelength of this emission depends upon added silver ion, shifting to the red (in aqueous or acetonitrile solution) (Fig. 2) as the [Ag]/[Ru] molar ratio increases. The shift is most dramatic at ratios of $100-1000$, with no shift within experimental error below 1OO:l ratio. The shift, in water, is about 2 nm larger in 0.1 M $KNO₃$ than in 0.01 M $KNO₃$.

Fig. 1. Absorption and emission spectra of the $\left[\text{Ru(bpz)}_3\right]^2$ cation in the absence of silver ion, and in the presence of silver nitrate at a molar ratio of $[Ag]/[Ru] = 10000:1$. The solution also contains 0.1 M KNO₃.

Fig. **2.** Uncorrected emission wavelength as a function of [Ag]/[Ru]. Lower data set (squares): acetonitrile containing 0.01 M TBAP. Upper data set $(+)$: water containing 0.1 M KNO3. Note the entry for 0 lies at 600 nm. The slit width was 2 nm, and the excitation wavelength 423 nm.

Fig. 3. Lifetime dependence as a function of [Ag]/[Ru]. (a) Acetonitrile (0) containing 0.01 M TBAP. (b) Water (\diamond) containing 0.1 M KNO₃. Although a straight line is shown through these data, the correlation is not necessarily linear. Excitation wavelength **423 nm.**

(b) Lifetime measurements. The lifetimes (Fig. 3) increase in acetonitrile and decrease in water with increasing $[Ag]/[Ru]$ ratio. The following empirical relationships pertain between lifetime (τ) , in ns, and the $[Ag]/[Ru]$ molar ratio:

 $(CH₃CN/0.01 M TBAP) \tau = 900 + 0.03 [Ag]/[Ru]$ *(R =* 0.985)

(Water/0.1 M KNO₃) $\tau = 1060 - 0.013$ [Ag]/[Ru] $(R = 0.947)$ (1)

A linear function is used for convenience to enable calculation of lifetimes at differing [Ag]/[Ru] ratio. However the correlation coefficients are not so good as to exclude a more complex dependence.

(c)Intensity *measurements. The* intensities, at a given emission wavelength, increase linearly in $CH₃CN/0.01$ M TBAP. with a 16% increase at a molar [Ag]/[Ru] ratio of 10000:1. In water, there is a decrease, which however is decidedly non-linear, being most extreme at low (<4000) molar [Ag]/[Ru] ratios.

(iii) Quenching Studies

The quenching of **l*** with various organic acceptors and donors in acetonitrile, and with metal ions in water, has been previously reported [8]. These

$$
I_0/I = 1 + K_{SV}[Q] = 1 + \tau_0 k_q[Q]
$$

studies are extended here through re-investigation in the presence of varying amounts of Ag' ion. In Fig. 4, and Table I, are shown Stern-Volmer slopes^{*}, $K_{\rm sv}$, for a variety of organic donors *versus* the [Ag]/[Ru] ratio, and the $E(Q^+/Q)$ potential. Quenching data for various metal ions in aqueous solution are also presented in Table I. N.B. All the above data are collected in nitrogen outgassed solutions. Oxygen is a fairly effective quencher.

Discussion

The UV-Vis/IR and especially NMR data show no detectable interaction between the ground state of **1** and silver ions under the conditions explored. The shift in wavelength of the emission from 1^* , and the increase in lifetime and intensity observed in acetonitrile solution show conclusively the interaction of silver ions with the lowest MLCT state of complex **1,** *i.e.* exciplexes are formed. The variation in lifetime and quenching K_{SV} values with $[Ag]/[Ru]$ ratio provides evidence for a series of $1(Ag_n)^*$ exciplexes, apparently in equilibrium with each other and with the silver ion. The possibility that the shift in peak emission wavelength maxima occurs through solvent dielectric changes is reduced by the use of constant ionic strength solutions, at least at lower [Ag]/[Ru] ratios. At high [Ag]/ [Ru] ratios, the silver ion concentration exceeds that of TBAP and may therefore introduce solvent dielectric effects. To increase the TBAP concentration is not practical due to precipitation ofl.

^{*}The **Stern-Volmer slope is obtained from a plot of intensity of emission (I), as a function of quencher concentration [Q], with respect to the unquenched emission intensity 10 via:**

where τ_0 is the lifetime of the excited state and k_{α} is the **quenching rate constant.**

Fig. 4. Stern-Volmer slopes, K_{sy} as a function of quencher potential and $[Ag]/[Ru]$ in acetonitrile (with 0.01 M TBAP). The data are collected from a series of methoxybenzenes as listed in Table I. From left to right on each line the [Ag]/[Ru] ratios are **0, 1000,500O** and 10000.

^eNo quenching observed in the absence of silver ion [8].

It does not appear possible from the data available to determine the values of n . The simplest explanation is that one silver atom is bound readily in the $[Ag]/[Ru] = 100-2000:1$ range, and that a second binds with difficulty in the 2000-10000:1 range. However the data do not distinguish an alternative explanation, namely, that in a manner similar to protonation [141, three silver atoms bind in the lower [Ag]/ [Ru] range one on each bipyrazine ring, and that $4-6$ silver atoms bind in the higher $[Ag]/[Ru]$ range. Given the increased shifts in emission wavelength for given $[Ag]/[Ru]$, with increasing ionic strength, multiple silver ion binding is inferred. For the purposes of discussion, therefore, the latter possibility will be assumed.

The red shift in the emission maximum reflects the Lewis acidity of the Ag⁺ ions which stabilize slightly the π^* levels involved in the MLCT transition. The extended lifetime of the silver bound excited states in acetonitrile solution may reflect reduced solvent collisional deactivation of the excited state whose wave function may not extend significantly over the silver ions.

The 3MLCT excited **l*** cation is an excellent oxidizing agent with a potential of $+1.45$ V for the couple $[Ru(bpz)_3^{2**}]/[Ru(bpz)_3^+]$, being about 0.7 V more positive than for the corresponding couple for 2 ^{*} [8]. The excited state potential of the species $[Ru(bpz)_3Ag_n]^{2+n*}$ can be determined via quenching studies (restricted by the requirement that the quencher does not react with silver ion, eliminating, for example, quenching by aromatic amines and nitro derivatives).

The (reductive) quenching data for a range of alkoxybenzenes do indeed reflect the increased oxidizing ability of the $1(Ag_n)^*$ system when compared to I* in the absence of silver (Table I). The K_{SV} values increase with decreasing $E(Q^+/Q)$ and increasing [Ag]/[Ru] ratio (Fig. 4, Table I). However we note that if the K_{SV} values are corrected for the variation in lifetime (via eqn. (1)), then the resulting k_q values (Table I) tend to be independent of the $[Ag]/[Ru]$ ratio above about 2000:1.

Applying the Rehm-Weller theory [23] to the data as discussed previously [8], and assuming that the encounter volume and diffusion rate constants remain unchanged (a pragmatic assumption given the rather limited accuracy of this type of experiment) the data (for high [Ag]/[Ru] ratio) may be fitted with an excited state reduction potential of about I .55 V, or about 100 mV more positive than for **l*** alone. The data are not good enough to delineate any special dependence upon n . Given that there is also a shift of about 100 mV to the red, in the emission energy at high $[Ag]/[Ru]$ ratio, the silver ions and the increased positive charge they impose, have actually increased the oxidizing power of 1* by about 200 mV, half of which is wasted.

Table I also includes data for quenching by metal ions in aqueous solution. Indeed the species may be a better oxidizing agent in aqueous solution than in acetonitrile wherein the (formal) 8+ charge is probably largely vitiated by ion pairing. However, in contrast to the acetonitrile data, the trends in the metal quenching data are for a reduction of K_{SV} , and k_{α} , with increasing $[Ag]/[Ru]$ irrespective of whether the metal ion is a reductive quencher such as $Fe²⁺$ or an oxidative quencher such as $[Co(NH_3)_5Cl]^2$, or perhaps Cu²⁺. This trend is seen most readily in the $Cu²⁺$ and $Ni²⁺$ data shown in Table I.

The dominant factor in this aqueous metal ion quenching is the increasing positive charge of the excited state species, with increasing [Ag]/[Ru], causing repulsion of these positively charged quenchers. Indeed this may be evidence that the number of silver ions bound to **l*** does increase with increasing $[Ag]/[Ru]$. Note further that K_{SV} does increase with increasing ionic strength for a given [Ag]/[Ru] ratio.

Conclusions

The $[Ru(bpz)_3(Ag_n)]^{(2+n)+*}$ exciplexes are photocatalysts which should prove valuable for neutral or negatively charged quenchers which can tolerate excess silver ion. They also represent an interesting avenue for tuning the excited state potential of the $[Ru(bpz)_3]^2$ ⁺ photocatalyst. Further studies are planned.
