Received October 21, 1976

The study of dipeptide-metal-nucleoside complexes, as models for the enzyme-metal-nucleic interactions, is most interesting to understand the many enzymic and other catalytic processes requiring metal ions [1]. We report here the synthesis and characterisation (by i.r. and  $^1\text{H}$  n.m.r. spectroscopies) of the hydrated complexes of glycyl-L-tyrosine ( $\text{H}_2\text{GT}$ )

of general formulae  $\text{M}(\text{H}_n\text{GT})\text{X}$ , and of those of  $\text{H}_2\text{GT}$  and cytidine (Cyd)

of general formulae  $\text{M}(\text{GT})(\text{Cyd})$  ( $\text{M} = \text{Co}^{\text{II}}, \text{Cu}^{\text{II}}$ ,  $\text{X} = \text{H}_2\text{O}$ ,  $n = 0$ ,  $\text{X} = \text{Cl}$ ,  $n = 1$ ) as well as of the charged species  $[\text{Cu}(\text{HGT})\text{Cyd}]\text{NO}_3$

### Experimental

#### $\text{Cu}(\text{GT})\text{H}_2\text{O}$

The complex was prepared by addition of commercial  $\text{H}_2\text{GT}$  ( $0.238 \text{ g}, 10^{-3} \text{ M}$ ) to an aqueous suspension of  $\text{Cu}(\text{OH})_2$  ( $1.25 \cdot 10^{-3} \text{ M}$ ) at  $\text{pH} = 6.5$ , according to A. R. Manyak *et al.* [2]. The product was recrystallised by slow evaporation of an aqueous solution.

#### $\text{Co}(\text{GT})\text{H}_2\text{O} \cdot 2\text{H}_2\text{O}$

A water-methanol (1/1) solution of  $\text{H}_2\text{GT}$  ( $0.238 \text{ g}, 10^{-3} \text{ M}$ ) was added to a water solution of  $\text{Co}(\text{CH}_3\text{COO}^-)_2 \cdot 4\text{H}_2\text{O}$  ( $0.249 \text{ g}, 10^{-3} \text{ M}$ ). The solution ( $\text{pH} = 5.9$ ) was heated ( $60^\circ\text{C}$ ) and stirred for 4 hr, under nitrogen, then evaporated to dryness.

The final product was redissolved in methanol and precipitated by diffusion of diethylether.

#### $\text{Cu}(\text{HGT})\text{Cl} \cdot 2\text{H}_2\text{O}$

An aqueous solution of  $\text{H}_2\text{GT}$  ( $0.238 \text{ g}, 10^{-3} \text{ M}$ ) and of  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$  ( $0.215 \text{ g}, 1.25 \cdot 10^{-3} \text{ M}$ ) were stirred at room temperature and at  $\text{pH} = 3.65$  for 2 hr. The complex was then isolated by addition of ethanol-diethylether (2/1).

#### $\text{Co}(\text{HGT})\text{Cl} \cdot \text{H}_2\text{O}$

$\text{H}_2\text{GT}$  ( $0.476 \text{ g}, 2 \cdot 10^{-3} \text{ M}$ ) and  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$  ( $0.475 \text{ g}, 2 \cdot 10^{-3} \text{ M}$ ) dissolved in water were stirred and heated ( $40^\circ\text{C}$ ) for 9 hr. After cooling, the solution ( $\text{pH} = 4.6$ ) was filtered to remove the unreacted  $\text{H}_2\text{GT}$ . The complex was isolated by addition of acetone.

#### $\text{Cu}(\text{GT})\text{Cyd} \cdot 2\text{H}_2\text{O}$

The complex was synthesised according to Szalda *et al.* [3], from  $0.084 \text{ g}$  ( $0.34 \cdot 10^{-3} \text{ M}$ ) of cytidine and  $0.105 \text{ g}$  ( $0.34 \cdot 10^{-3} \text{ M}$ ) of  $\text{Cu}(\text{GT})\text{H}_2\text{O}$ , and precipitated by addition of methanol-diethylether (1/1).

#### $\text{Co}(\text{GT})(\text{Cyd}) \cdot 6\text{H}_2\text{O}$

The same method as for  $\text{Cu}(\text{GT})(\text{Cyd}) \cdot 2\text{H}_2\text{O}$  was followed.

#### $[\text{Cu}(\text{HGT})\text{Cyd}]\text{NO}_3 \cdot 4\text{H}_2\text{O}$

A solution of the  $[\text{Cu}(\text{HGT})]^+$  cation was obtained by addition of  $\text{AgNO}_3$  ( $0.043 \text{ g}, 0.25 \cdot 10^{-3} \text{ M}$ ) to an aqueous solution of  $\text{Cu}(\text{HGT})\text{Cl} \cdot 2\text{H}_2\text{O}$  ( $0.100 \text{ g}, 0.25 \cdot 10^{-3} \text{ M}$ ). The solution was filtered to remove the precipitated  $\text{AgCl}$ , and  $0.062 \text{ g}$  ( $0.25 \cdot 10^{-3} \text{ M}$ ) of cytidine were added to the pale-green filtrate. The resulting solution turned immediately blue and was heated at  $60-70^\circ\text{C}$  for 2 hr, when the colour had become deep green. The resulting complex was isolated by addition of acetone, and recrystallised by slow evaporation from an aqueous solution.

The microanalytical results (C, H, N, see Table) agree satisfactorily with the proposed formulae. The i.r. spectra ( $4000-400 \text{ cm}^{-1}$ ) were obtained from KBr pellets on a Beckman IR 12 spectrophotometer. The  $^1\text{H}$  n.m.r. spectra were recorded on a FT Bruker WH 90 spectrometer, from  $\text{DMSO-d}_6$  solutions with  $\text{Me}_4\text{Si}$  as internal standard.

### Results and Discussion

The presence of the  $\nu$  and  $\delta(\text{NH}_3)$ ,  $\nu_{\text{as}}$  and  $\nu_{\text{s}}(\text{COO}^-)$  vibration bands in the i.r. spectrum of the free dipeptide  $\text{H}_2\text{GT}$  indicates the gly-L-tyr to be zwitterionic. In the isolated complexes, the bands due

<sup>a</sup> H<sub>2</sub>GT:  $\nu(\text{N}^+\text{H}_3) = 3030 \text{ cm}^{-1}$ ;  $\nu(\text{COO}^-) = 1603 \text{ cm}^{-1}$ ; amide I =  $1660 \text{ cm}^{-1}$ , S,

<sup>b</sup> Cyd:  $\nu(\text{C=O}) = 1675 \text{ S}$ ;  $\nu(\text{C=N}) = 1635 \text{ S}$ . S = strong; br = broad; m = medium.

to the <sup>+</sup>NH<sub>3</sub> group have disappeared, while those associated to COO<sup>-</sup> are shifted to lower frequencies ( $1585 \text{ cm}^{-1}$ ). We suppose therefore that the gly-L-tyr is always bound to the metal through both its terminal groups -NH<sub>2</sub> ( $\nu(\text{NH}_2)$  at  $3200\text{--}3250 \text{ cm}^{-1}$ ) and -COO<sup>-</sup>.

Whereas to the peptide bond -CONH-, two different binding ways are possible according to the reactional pH range. In the complexes I, II, V and VI prepared at pH = 6–7, the amide I band position at  $1600\text{--}1605 \text{ cm}^{-1}$  suggests, as shown by Martell and Kim [4], that the peptide bond is bound through the deprotonated nitrogen. On the contrary, at pH lower than 5.5 (in the case of complexes III, IV and VII), the peptide N is protonated and therefore less likely to bind to the metal ion. The corresponding shift of the  $\nu$  (amide I) to  $1620\text{--}1625 \text{ cm}^{-1}$  suggests a coordination through the ketone group [4]. This is confirmed by the crystal structure of an analogous complex, chloroglycyl-glycinato copper II monohydrate, reported by Shiro *et al.* [5], where the peptide bond is indeed co-ordinated through the oxygen.

Our results are further confirmed by a titration study of gly-L-tyr in presence of Cu<sup>II</sup> ions, with the loss of 2 protons (from <sup>+</sup>NH<sub>3</sub> and -CONH-), at pH values higher than 6, as shown by Dobbie *et al.* [6].

The i.r. spectra of the mixed ligands complexes indicate the cytidine to be coordinated through N3, since the  $\nu(\text{C=N})$  bands have disappeared. Moreover, in the case of Cu(GT)Cyd·2H<sub>2</sub>O and Co(GT)Cyd·6H<sub>2</sub>O the  $\nu(\text{C=O})$  band is shifted from  $1675 \text{ cm}^{-1}$  (in the free cytidine) to  $1655$  and  $1658 \text{ cm}^{-1}$  respectively. This suggests the ketone group to interact with the metal ion. Szalda *et al.* [3] have indeed put into evidence such a Cu-O interaction by X-ray analysis of the analogous complex Cu<sup>II</sup>(glycyl-

Figure. <sup>1</sup>H n.m.r. spectra in DMSO-d<sub>6</sub> solution of: (a) glycy-L-tyrosine alone (0.1 M) and in presence of (b)  $2.10^{-5} \text{ M}$ , (c)  $2.10^{-4} \text{ M}$  CuCl<sub>2</sub>; (a') cytidine alone (0.1 M) and in presence of (b')  $2.10^{-5} \text{ M}$ , (c')  $10^{-4} \text{ M}$  Cu(GT)H<sub>2</sub>O.

glycine)Cyd, where the coordination geometry about the copper atom is approximately square pyramidal. However, no such interaction appears to take place in the charged species [Cu(HGT)Cyd]NO<sub>3</sub>·4H<sub>2</sub>O, since the  $\nu(\text{C=O})$  band appears at a higher frequency (see Table). This may be explained by the competitive presence of the NO<sub>3</sub> anion near the metal ion.

The Cu<sup>II</sup> and Co<sup>II</sup> broadening effect on the p.m.r. lines of the free ligands was used to identify the nature of the different binding sites.

When adding progressively  $2.10^{-4} \text{ mol}$  of CuCl<sub>2</sub> to a solution of gly-L-tyr in DMSO at pH = 6 (see Figure), the CH<sub>2 $\alpha$</sub>  proton resonance is the first to

broaden and then to disappear. The adjacent  $\text{NH}_2$  group should therefore be the first coordination site. When  $10^{-3}$  mol of  $\text{CuCl}_2$  are added, the peptide proton and the  $\text{CH}_\alpha$  signals are also affected, indicating that the peptide N and the terminal carbonyl group react in a second time [7].

In the case of the mixed ligand complexes, when adding the paramagnetic complex  $\text{Cu}(\text{GT})\text{H}_2\text{O}$  to the free cytidine, the H-5 doublet is the first to broaden and disappear while the H-6 resonance does not broaden appreciably and remains a doublet. This indicates a greater vicinity of H-5 than H-6 to the coordination site and we suppose therefore the cytidine to have reacted with  $\text{Cu}^{\text{II}}$  and  $\text{Co}^{\text{II}}$  through N3 [8].
