

## Pyrazolato and Related Anions. Part IV. Salts of 4-Nitropyrazole

G. NIEUWPOORT, J. G. VOS\* and W. L. GROENEVELD

*Gorlaeus Laboratories, Rijksuniversiteit Leiden, P.O. Box 9502, 2300 RA Leiden, The Netherlands*

Received November 3, 1977

*A number of metal salts of 4-nitropyrazole (HNO<sub>2</sub>Pz) is reported. Salts of Cd, Zn, Mn, Co, Ni and Cu are synthesized from ammonia solution, or by addition of NaOH to a HNO<sub>2</sub>Pz complex in water.*

*The compounds are identified and characterized by chemical analyses, infrared and ligand field spectra. The pyrazolato anion coordinates as a bidentate ligand. In the salts of Cd, Mn, Co, Ni, and Cu ammonia and water molecules are participating in the coordination of the metal ion. A tentative vibrational assignment of salts and neutral ligand is given.*

### Introduction

This paper is a part of our investigations on salts of pyrazoles. Earlier papers [1, 2] dealt with the preparation and characterization of salts of pyrazole (HPz), 4-chloropyrazole (HClPz), 4-bromopyrazole (HBrPz) and 4-iodopyrazole (HIPz).

Coordination complexes of neutral 4-nitropyrazole (HNO<sub>2</sub>Pz) have been published and used for an assignment of the infrared spectrum of the HNO<sub>2</sub>Pz ligand by Reedijk *et al.* [3]. The preparation and the far-infrared spectrum of Ag(NO<sub>2</sub>Pz) have been reported by Okkersen [4].

In the salts of HPz and HXPz a correlation between the  $pK_{\text{base}}$  of the neutral ligand and the spectra of the obtained products is not conclusive. The ligand field spectra give an indication of a reflex of the  $pK_{\text{base}}$  on the nephelauxetic effect, but a possible shift in metal–ligand vibrations in the far-infrared spectrum of halogenopyrazolates is obscured by an interaction between metal–ligand vibrations and carbon–halogen vibrations [2]. In HNO<sub>2</sub>Pz these interacting ligand vibrations are absent and the low  $pK_{\text{base}}$  of HNO<sub>2</sub>Pz (–1.96) may yield more information about the correlation between this  $pK_{\text{b}}$  and the ligand field spectra. So the salts of this pyrazole derivatives have been prepared and investigated. In this paper a tentative assignment of the salts has been given, mainly based on the infrared and Raman spectra of the zinc compound. This assignment has been used for the description of the infrared and Raman spectra of the neutral ligand.

### Experimental

4-nitropyrazole was synthesized as described by Morgan [5]. Commercially available metal salts were used without further purification. To obtain the pyrazolato salts two procedures were followed: 1) a hydrated metal chloride was added to HNO<sub>2</sub>Pz, both dissolved in 25% aqueous solution of ammonia.

2) addition of NaOH to a solution of a HNO<sub>2</sub>Pz solvated metal complex in water.

In both cases the salts were obtained as precipitates, centrifugated, washed with water, ethyl alcohol and diethyl ether and finally dried *in vacuo* at room temperature (Table I, 1a, 2a). Compounds which contained water and ammonia were heated at 180 °C (Table I, 1b, 2b). No decomposition of the salts was found up to 250 °C. The Mn(II) and Co(II) salts appeared to be sensitive to oxygen and had to be prepared in N<sub>2</sub> atmosphere. The dry Mn(II) compound could be isolated but the Co(II) compound, obtained as a yellow powder from ammonia solution was oxidized very rapidly. We only succeeded in recording ligand field and infrared spectra of this compound, while no satisfactory analyses were obtained. These spectral data are given because of the importance of this compound in the present series. The information obtained from infrared and ligand field spectra is in agreement with the formula Co(NO<sub>2</sub>Pz)<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>·xH<sub>2</sub>O.

1-D,4-nitropyrazole was prepared by refluxing of a solution of HNO<sub>2</sub>Pz in D<sub>2</sub>O.

From infrared intensity measurements the deuteration appeared to be completed for about 90%.

### Physical Measurements and Analyses

Thermal analytical measurements were carried out by Mr. W. Cramer on a Mettler Vacuum Thermal Analyzer TA-1. The compounds were heated up to 300 °C at a rate of 8 °C/min in nitrogen atmosphere. Diffuse reflectance spectra were obtained on a Beckman DK-2A ratio recording spectrophotometer with MgO as a reference. Infrared spectra were recorded on a Perkin–Elmer 580 infrared spectrophotometer (4000–180 cm<sup>–1</sup>), as nujol mulls and Cs I pellets (wavenumber accuracy better than 2 cm<sup>–1</sup>).

<sup>a</sup>Calculated values are in parentheses.

Laser-Raman spectra were recorded on a Jeol JRS-4000 Laser-Raman spectrophotometer equipped with a Coherent Radiation CR-2 Argon gas ion laser. Spectra of the solid compounds in capillaries were measured at both the 514.5 and 488.0 nm lines; CCl<sub>4</sub> served as a calibrant. Wavenumbers are believed to be accurate to 3 cm<sup>-1</sup> in all regions. Raman spectra were recorded at the Vrije Universiteit in Amsterdam by Dr. M. W. G. de Bolster. Metal analyses were carried out by complexometric titrations after decomposition by heating in nitric acid. Carbon, hydrogen, and nitrogen analyses were carried out by the Micro-analytical Department of Organisch Chemisch Instituut TNO, Croesestraat 79 Utrecht, under the supervision of Mr. W. J. Buis.

## Results and Discussion

### Thermoanalytical Experiments

The compounds Ni(NO<sub>2</sub>Pz)<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>·2H<sub>2</sub>O and Cu(NO<sub>2</sub>Pz)<sub>2</sub>(NH<sub>3</sub>) were subjected to thermoanalytical measurements. The DTG curve of the Ni salt shows a decrease in weight of 9% at 160 °C. This is in agreement with a loss of two mol NH<sub>3</sub> (theor. 9.6%) or H<sub>2</sub>O (theor. 10.1%). A strong DTA peak is

observed at 156 °C. This peak is probably caused by the transition from Ni(NO<sub>2</sub>Pz)<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>·2H<sub>2</sub>O to the green Ni(NO<sub>2</sub>Pz)<sub>2</sub>(H<sub>2</sub>O)<sub>2</sub>. In Ni(BrPz)<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>·2H<sub>2</sub>O this transition is found at 200 °C. We therefore assume that the ammonia molecules are lost first and that the removal of the water is taking place in a more moderated way. This is in agreement with the observed infrared and ligand field spectra of the compounds which are dried at 180 °C.

For Cu(NO<sub>2</sub>Pz)<sub>2</sub>(NH<sub>3</sub>) a DTA peak is observed at 250 °C. The DTG curve indicates a loss of weight of 7.5% at 250 °C. We ascribe this transition to the formation of the compound Cu(NO<sub>2</sub>Pz)<sub>2</sub>, with an expected loss of weight of 5.6% for the removal of the NH<sub>3</sub>.

### Infrared Spectra

The symmetry of NO<sub>2</sub>Pz<sup>-</sup> with the five-membered ring and NO<sub>2</sub> group in plane is C<sub>s</sub> or C<sub>2v</sub>. Taking the Y-axis perpendicular to the plane and excluding metal-ligand and N-H vibrations in C<sub>2v</sub> symmetry the normal modes 9A<sub>1</sub>, 8B<sub>1</sub>, 3A<sub>2</sub> and 4B<sub>2</sub> are expected.

When the symmetry is C<sub>s</sub>, the normal modes are 17A' and 7A''. All fundamentals are active in the Raman spectrum. Only the A<sub>2</sub> modes are infrared inactive.

<sup>a</sup> s = strong, m = medium, w = weak, sh = shoulder, v = very, br = broad, — = not investigated.

For both the neutral ligand in solid state and the coordinated anion in the solid compounds a  $C_{2v}$  symmetry can be concluded from the infrared and Raman spectra (see Table II). For the anion this is in agreement with a bidentate coordination via the nitrogen atoms. In other pyrazoles in the solid state hydrogen bonding causes a 'pseudo  $C_{2v}$ ' symmetry. The  $C_{2v}$  symmetry is distorted by distinction in the N-H bonds. In  $HNO_2Pz$  these N-H bonds are probably much more comparable as the low  $pK_b$  correlates with weakened N-H bindings and this might explain the  $C_{2v}$  symmetry for the neutral ligand in the solid state. In transition metal complexes of the neutral ligand a  $C_s$  symmetry is found (Fig. 1a, b, c). In Table

II infrared and Raman data of salts of  $HNO_2Pz$  are listed, together with data of the complex  $NiCl_2 \cdot (HNO_2Pz)_4$  and the neutral ligand itself.

For the description of the normal vibrations, we used the assignments of pyrazole and halogeno pyrazoles, which we reported in a previous paper [7], as far as the vibrations of the five-membered ring are concerned. For the normal modes associated with the C-NO<sub>2</sub> group assignments of other nitrocompounds as nitromethane [8], nitrobenzene [9-11] and 3-nitrotriazole [12, 13] were compared with the earlier assignment of 4-nitropyrazole reported by Reedijk [3].

The concept for the vibrations of nonsubstituted five-membered rings is based on the following con-

Figure 1. Infrared spectra of  $Ni(HNO_2Pz)_4Cl_2$ ,  $HNO_2Pz$  and  $Zn(NO_2Pz)_2$  as CsI pellets between 4000–400  $cm^{-1}$ .

siderations.  $A_1$  and  $B_1$  vibrations are usually found at wavenumbers higher than  $900\text{ cm}^{-1}$  [3, 6, 14–16]. Raman spectra were recorded in order to be able to assign the  $A_1$  modes, as these modes usually give rise to strong Raman absorptions. The remaining bands above  $900\text{ cm}^{-1}$  are  $B_1$  modes. Differentiation between the  $A_2$  and  $B_2$  modes in the  $600\text{--}900\text{ cm}^{-1}$  region can easily be made, as the  $A_2$  species are infrared inactive. For a number of vibrations associated with the nitro group the assignments are rather controversial, especially the C–N modes. The  $\nu\text{C–N}$  in nitrobenzene for example is found at  $850\text{ cm}^{-1}$  according to Stephenson [9] and at  $1266\text{ cm}^{-1}$  according to Mooney [10]. In 3-nitrotriazole [12] the  $\nu\text{C–N}$  is held responsible for a band at  $1510\text{ cm}^{-1}$ . In this last paper the C–N bond length, based on a X-ray diffraction analysis [13], is reported to be  $1.40\text{ \AA}$ , in which case the  $\nu\text{C–N}$  indeed should be found higher than  $1300\text{ cm}^{-1}$  [10]. We therefore attribute a band at  $1440\text{ cm}^{-1}$  to the C–N stretch mode. The C–N bending modes are assigned to bands

Figure 2. Raman spectra of  $\text{HNO}_2\text{Pz}$  and  $\text{Zn}(\text{NO}_2\text{Pz})_2$  in the solid state between  $1600\text{--}100\text{ cm}^{-1}$ .

at  $480$  and  $210\text{ cm}^{-1}$  in  $\text{Zn}(\text{NO}_2\text{Pz})_2$ , whereas the  $-\text{NO}_2$  twisting should be found at low wavenumber [11] and is therefore not observed. The other  $-\text{NO}_2$  vibrations are taken from the literature [8–12].

In Table III the  $\text{NH}_3$  rocking frequency of a number of compounds is listed. The  $\text{NH}_3$  rocking vibration is the most sensitive to the nature of the metal of all  $\text{NH}_3$  vibrations: the higher the rocking frequency the stronger the  $\text{M–NH}_3$  bond [17].

<sup>a</sup>Taken from  $\text{Cu}(\text{NH}_3)_4\text{Cl}_2$ .

From this data the order of strength of the  $\text{M–N}$  bond appears to be  $\text{Cu} > \text{Ni} > \text{Co} > \text{Mn} \approx \text{Cd}$ . In salts of  $\text{HNO}_2\text{Pz}$  the  $\text{NH}_3$  molecules are coordinated more strongly than in the salts of halogeno pyrazoles. In all reported compounds the  $\text{NH}_3$  rocking vibrations are found at lower wavelengths than in the corresponding hexammine complexes of the metal chlorides [17].

#### Far-infrared Spectra

Far-infrared spectra were recorded in order to obtain information about the metal–ligand bond. The spectral data are listed in Table IV. As stated in Part I of this series the symmetry round the metal ion is  $D_{2d}$ ,  $D_{2h}$  or  $D_2$ , when the ligand is included. In the first two cases, where the nitrogen atoms are coordinating with respectively square-planar and tetrahedral symmetry, two infrared active metal–ligand stretch vibrations are expected. When the direct symmetry round the metal is not  $D_{4h}$  or  $T_d$  the overall symmetry is  $D_2$  and three metal–ligand stretch bands become infrared active.

The observed metal–ligand bands follow the Irving–Williams sequence, and are found in a region which is normal for nitrogen donor ligands, but at wavelengths higher than in the corresponding complexes of the neutral ligands [3, 18]. The metal–ligand vibrations in nitropyrazole salts occur at lower wavenumbers than in the salts of pyrazole [1]. Differences of about  $10\text{ cm}^{-1}$ , which are usually found comparing complexes of the neutral ligands [3], are observed here as well. This shift is probably caused by the lower  $\text{pK}_b$  of nitropyrazole, but also the higher mass of this ligand might be important. For the Ni salt the observed difference is much larger. This is apparently caused by a different coordination of the metal ion. In  $\text{Ni}(\text{Pz})_2$ , where metal–ligand bands are

found at 452 and 408  $\text{cm}^{-1}$ , a square-planar arrangement is found from the ligand field spectrum.

In  $\text{Ni}(\text{BrPz})_2(\text{NH}_3)_2 \cdot 2\text{H}_2\text{O}$  an infrared band at 320  $\text{cm}^{-1}$  has been assigned as a M-NH<sub>3</sub> stretch mode [2]. In the now reported compounds this stretch vibration is expected to occur at about the same wavelength. No definite assignment can be made because other metal-ligand vibrations are present in this region.

#### Ligand Field Spectra

Ligand field spectra were recorded in order to obtain information about the direct environment of the metal ion. The spectral data are listed in Table V. The ligand field spectrum of the Co(III) salt is in agreement with a low spin octahedral coordinated metal ion. Compared with the Co(III) salts, which we reported earlier, the absorption band which is ascribed to the  ${}^1\text{T}_{1g} \leftarrow {}^1\text{A}_{1g}$  transition shifts to higher wavelengths. So the assumption we made that a lower  $\text{pK}_b$  induces a higher value for the  $F_4$  parameter

seems to be realistic [2]. From the absorption bands of the Co(II) salt (see Experimental) an octahedral coordination of the metal ion is expected.

The calculated spectral parameters [19] are  $Dq = 1110 \text{ cm}^{-1}$  and  $B = 825 \text{ cm}^{-1}$ . From the infrared spectrum and the ligand field spectrum it is evident that the ammonia molecules are coordinated. In the Co(II) salts reported earlier [2], the cobalt ions were coordinated tetrahedrally; no ammonia molecules were present.

The ligand field spectrum of  $\text{Ni}(\text{NO}_2\text{Pz})_2(\text{NH}_3)_2 \cdot 2\text{H}_2\text{O}$  indicates octahedral coordinated metal ions. For this mixed complex we calculate [20]  $Dq = 1130 \text{ cm}^{-1}$  and  $B = 830 \text{ cm}^{-1}$ . For  $\text{Ni}(\text{BrPz})_2(\text{NH}_3)_2 \cdot 2\text{H}_2\text{O}$  [2] we observe an almost equal value for  $Dq$  (1140  $\text{cm}^{-1}$ ) and a lower value for  $B$  (766  $\text{cm}^{-1}$ ). With the rule of average environment [21] we calculate a  $Dq$  value of 1155  $\text{cm}^{-1}$  for the  $\text{NO}_2\text{Pz}^-$  salt; for  $\text{BrPz}^-$  we found 1170  $\text{cm}^{-1}$ .

In  $\text{Ni}(\text{NO}_2\text{Pz})_2(\text{H}_2\text{O})_2$  the water is coordinated, which results in a pseudo-octahedral coordination.

The ligand field bands observed for the Cu salts are found at wavelengths which are too high for tetrahedral coordination. From the infrared spectra of the blue Cu(II) salt, coordination of ammonia is evident. We therefore expect a five coordination in this compound. A square-planar coordination is expected for  $\text{Cu}(\text{NO}_2\text{Pz})_2$ .  $\text{NO}_2\text{Pz}^-$  seems to coordinate less strongly than the anions we reported before. Instead of a square-planar Ni compound a distorted octahedral coordination is observed and an octahedral Co(II) salt including coordinated  $\text{NH}_3$  molecules is found instead of a tetrahedral Co(II) salt. As we stated in the infrared part of this paper, the coordination of ammonia in the salts of  $\text{HNO}_2\text{Pz}$  is stronger than in the salts of the halogenopyrazoles. We might conclude from this that when the anion becomes a weaker ligand the  $\text{NH}_3$  molecules are coordinating more strongly and almost identical pseudo octahedral coordinations are obtained. The higher value for B in  $\text{Ni}(\text{NO}_2\text{Pz})_2(\text{NH}_3)_2 \cdot 2\text{H}_2\text{O}$  might be explained by stronger coordinating ammonia molecules as well as by the lower  $\text{pK}_b$  of the neutral ligand.

### Conclusions

(i) In all salts the anion possesses  $\text{C}_{2v}$  symmetry and therefore acts as a bidentate ligand.

(ii) The low  $\text{pK}_b$  of  $\text{HNO}_2\text{Pz}$  probably causes weaker coordination of the anion than in salts of pyrazole.

(iii) Because of the weaker coordination of  $\text{NO}_2\text{Pz}^-$  ammonia molecules are taking part in the coordination of the metal ion in a number of salts.
