(Received October 10, 1991)

Pyridazine-bridged metal complexes have been extensively studied. Nearly all these investigations have involved the use of binucleating ligands [1, 2]. Established structures involve either polymeric or binuclear arrangements.

We have developed a new approach in which we use metal complexes of quadridentate bis-pyridazinecarboxamides as ligands [3]. We now report that coordination of these metal complexes to metal halides yields the first examples of trinuclear complexes involving pyridazine bridging, as illustrated in I.

I,  $[M(\text{bpdpn})]_2M'\text{Hal}_2$  (involving N,N-coordination by  $M(\text{bpdpn})$  to  $M'\text{Hal}_2$ ).

Examples are shown in Table 1 of parent metal bis-pyridazinecarboxamide complexes of the type  $M(\text{bpdpn})$  ( $\text{H}_2\text{bpdpn} = N,N'$ -bis(3'-pyridazinecarboxamide)-1,3-propane). Also shown are trimetallic products obtained by coordinating these  $M(\text{bpdpn})$  complexes to metal chlorides.

The deprotonated ligand  $\text{bpdpn}^{2-}$  appears to act as a distorted square-planar  $N_4$ -donor in the parent

\*Author to whom correspondence should be addressed.

TABLE 1. Magnetic data for parent  $M(\text{bpdpn})$  complexes and the resulting trimetallic  $\{M(\text{bpdpn})\}_2M'\text{Cl}_2$  complexes

Compound <sup>a</sup>	$\mu_{\text{eff}}$ (BM) <sup>b</sup>		$\theta$ (K) <sup>c</sup>
	304 K	89 K	
$\text{Cu}(\text{bpdpn}) \cdot 2\text{H}_2\text{O}^d$	1.95	1.87	-13
$\text{Ni}(\text{bpdpn}) \cdot 2\text{H}_2\text{O}^d$	diamagnetic		
$\{\text{Cu}(\text{bpdpn})\}_2\text{CuCl}_2^b$	1.55	1.10	<sup>e</sup>
$\{\text{Cu}(\text{bpdpn})\}_2\text{NiCl}_2$	3.62 <sup>f</sup>	2.48	-210 <sup>g</sup>
$\{\text{Ni}(\text{bpdpn})\}_2\text{NiCl}_2$	3.24	3.08	-10

<sup>a</sup>Satisfactory elemental analyses were obtained for all compounds. <sup>b</sup>The  $\mu_{\text{eff}}$  values in parentheses for  $\{\text{Cu}(\text{bpdpn})\}_2\text{CuCl}_2$  are calculated per mole of  $\text{Cu}^{\text{II}}$ . The remaining data are all calculated per mole of complex. <sup>c</sup>Curie-Weiss law taken as  $\chi^{-1} = C(T - \theta)$ . <sup>d</sup>Data from ref. 3. <sup>e</sup>Non-linear over the temperature range. <sup>f</sup>Measured at 299 K. <sup>g</sup>Deviated from linearity at lower temperatures.

$M(\text{bpdpn})$  complexes. This is shown by an X-ray structure analysis of  $[\text{Cu}(\text{bpdpn})\text{H}_2\text{O}] \cdot \text{H}_2\text{O}$  which has square-pyramidal  $N_4\text{O}$ -coordination with an apically coordinated water molecule [4]. Furthermore, the  $\text{Ni}^{\text{II}}$  complex  $\text{Ni}(\text{bpdpn}) \cdot 2\text{H}_2\text{O}$  is diamagnetic, in keeping with planar  $N_4$ -coordination. Also, Stephens and Vagg, as part of an extensive series of structure determinations, have shown that the  $\text{Cu}^{\text{II}}$  and  $\text{Ni}^{\text{II}}$  complexes with the corresponding bis-picolinamide ligand involve distorted square-planar  $N_4$ -coordination [5, 6].

The magnetic properties (Table 1) of the  $\text{Cu}_3$  and  $\text{Cu}_2\text{Ni}$  complexes indicate trinuclear structures, of the type illustrated in I, in which the metal bis-pyridazinecarboxamides act as bidentate N,N-donors, via the 1-pyridazine nitrogens, to the metal chloride entities. Both these complexes are strongly antiferromagnetic. The room temperature  $\mu_{\text{eff}}$  value (per  $\text{Cu}^{\text{II}}$ ) of the  $\text{Cu}_3$  complex is 1.55 BM; this is below the usual range of c. 1.8–2.0 BM for magnetically dilute copper(II). Furthermore the  $\mu_{\text{eff}}$  decreases to 1.10 BM at 89 K. The  $\mu_{\text{eff}}$  value (per mole of complex) of the  $\text{Cu}_2\text{Ni}$  complex is 3.62 BM at room temperature. This is similar to the calculated value of 3.55 BM for a high spin  $\text{Cu}^{\text{II}}_2\text{Ni}^{\text{II}}$  combination in which the constituent metals have typical  $\mu_{\text{eff}}$  values of 1.9 and 3.0 BM. The  $\mu_{\text{eff}}$  value for the  $\text{Cu}_2\text{Ni}$  complex decreases markedly to 2.48 BM at 89 K, yielding a large Weiss  $\theta$  constant of -210 K.

These magnetic data are good evidence for N,N-coordination by  $\text{Cu}(\text{bpdpn})$  leading to pyridazine bridging, which commonly produces strong antiferromagnetism [1, 2]. Furthermore, the temperature variations of the magnetic data fit trimer models [7]. The agreement  $R$  factors ( $R = [\sum(\chi_{\text{obs}} - \chi_{\text{calc}})^2 / \sum(\chi_{\text{obs}})^2]^{1/2}$ ) are 0.014 and 0.007 for the  $\text{Cu}_3$  and  $\text{Cu}_2\text{Ni}$  complexes, respectively [7]. In contrast, there is no significant magnetic interaction with the  $\text{Ni}_3$  complex, whose magnetism is consistent with the presence of two diamagnetic  $\text{Ni}(\text{bpdpn})$

entities and one paramagnetic nickel(II) chloride species.

The electronic spectra of the deeply coloured parent  $M(\text{bpdpn}) \cdot 2\text{H}_2\text{O}$  complexes contain intense absorption commencing at  $c. 15\,000\text{ cm}^{-1}$  and extending through the higher frequency region. In the trimetallic complexes, this absorption appears to be also present, largely unchanged. In the  $\text{Ni}_3$  and  $\text{Cu}_2\text{Ni}$  complexes, structures of type I are expected to produce additional absorption at  $c. 9\text{--}10\,000\text{ cm}^{-1}$ , associated with the  $\nu_1$  ( ${}^3\text{T}_{2g} \leftarrow {}^3\text{A}_{2g}$ ) absorption for the nickel(II) chloride entities. In these complexes, there is, in fact, evidence for weak, broad, additional absorption at  $c. 9\text{--}10\,000\text{ cm}^{-1}$ . With the  $\text{Cu}_3$  complex, absorptions from the copper(II) chloride and  $\text{Cu}(\text{bpdpn})$  species appear to overlap, because there is no significant absorption below  $c. 15\,000\text{ cm}^{-1}$ .

X-ray structural studies in this system are underway, and the results will be communicated in due course, together with the results of studies of the interaction of  $M(\text{bpdpn})$  entities with other metallic species.
