### Abstract

Two empirical models which express the relationship between the solute solubility and the concentration of one of the solvents in a binary solvent system are presented. The proposed models have been compared with previous similar models similar either in their original or modified forms from accuracy and predictability points of view using many experimental data taken from the literature. Both models were in some respects superior to the original and modified forms of the previous models. The modification of some of the previous models has improved the accuracy of the original models.

*Keywords:* Solubility; Binary solvent system; Cosolvency; Models for calculation

---

The use of solvent mixtures for affecting solubility has several applications in different fields of the pharmaceutical sciences including the formulation of liquid dosage forms. The quantification of drug solubility in the solvent mixtures enables one to predict and calculate the mixture composition for an optimum drug formulation. Several models are available for the calculation of the solubility in the solvent mixtures. In some models the solubility has been expressed in terms of the

physicochemical properties of the solute and solvent system (Yalkowsky et al., 1975; Martin et al., 1980; Acree et al., 1991; Acree and Tucker, 1994; Barzegar-Jalali et al., 1996). In other models, the relation between the solubility and the concentration of the solvents in a binary solvent system has been provided (Yalkowsky and Roseman, 1981; Williams and Amidon, 1984; Ochsner et al., 1985; Acree et al., 1991; Barzegar-Jalali and Hanaee, 1994).

In the present work, two empirical equations which express the relationship between the solubility and the concentration of one of the solvents

\* Corresponding author.

in a binary solvent system are given. The accuracy and predictability of the proposed equations are compared with those of the three-suffix excess free energy model (Williams and Amidon, 1984), mixture response-surface methodology (Ochsner et al., 1985) and nearly ideal binary solvent (NIBS)/Redlich–Kister model (Acree et al., 1991) as well as the modifications of the NIBS/Redlich–Kister model and the three-suffix excess free energy methods.

The proposed models are as follows:

$$\log(-\log X_m) = A_{-3}10^{-3f_a} + A_{-1}10^{-f_a} + A_0 + A_110^{f_a} + A_310^{3f_a} \quad (1)$$

$$\log(-\log X_m) = B_{-2}(\log f_a)^{-2} + B_{-1}(\log f_a)^{-1} + B_0 + B_1(\log f_a) + B_2(\log f_a)^2 \quad (2)$$

where  $X_m$  is the mole fraction solubility in the mixed solvent system,  $f_a$  denotes the concentration of one of the solvents in the binary solvent mixture expressed in volume and/or mole fraction, and the terms  $A$  and  $B$  are the parameters or constants of the models. Eq. (1) is applicable to all values of  $f_a$  from 0 to 1 whereas Eq. (2) holds for  $0 < f_a < 1$ .

The previously published equations which provide the relation between mole fraction solubility of the solute and concentrations of the solvents in the binary solvent system are the three-suffix excess free energy model (Eq. (3)), mixture response-surface methodology (Eq. (4)) and NIBS/Redlich–Kister model (Eq. (5)):

$$\log X_m = f_a \log X_a + f_b \log X_b + W_1 f_a f_b (2f_a - 1) + W_2 f_a^2 f_b + W_3 f_a f_b^2 \quad (3)$$

$$\log X_m = \beta_1 f_a + \beta_2 f_b + \beta_3 f_a^2 + \beta_4 f_b^2 + \beta_5 f_a f_b \quad (4)$$

$$\log X_m = f_a \log X_a + f_b \log X_b + f_a f_b [S_0 + S_1(f_a - f_b) + S_2(f_a - f_b)^2] \quad (5)$$

where  $f_a$  and  $f_b$  represent the volume and/or mole fraction concentrations of the solvents  $a$  and  $b$  in the binary system,  $X_a$  and  $X_b$  are mole fraction

solubilities of solute in the two neat solvents,  $W_1$ ,  $W_2$  and  $W_3$  are constants of the model which equal  $A_{1-3} q_2/q_1$ ,  $2A_{3-1} q_2/q_3$  and  $C_2$  in the original paper (Williams and Amidon, 1984), respectively.  $\beta_1$ – $\beta_5$  are coefficients of the model,  $f'_a$  and  $f'_b$  are given by:  $f'_a = 0.96f_a + 0.02$  and  $f'_b = 0.96f_b + 0.02$  (Ochsner et al., 1985), and  $S_0$ – $S_2$  are curve fitting parameters of the model.

In addition to the original models 3 and 5, the following modified forms of the models i.e. Eqs. (6) and (7) have been also used:

$$\log X_m = M_1 f_a + M_2 f_b + M_3 f_a f_b (2f_a - 1) + M_4 f_a^2 f_b + M_5 f_a f_b^2 \quad (6)$$

$$\log X_m = J_1 f_a + J_2 f_b + f_a f_b [J_3 + J_4(f_a - f_b) + J_5(f_a - f_b)^2] \quad (7)$$

where  $M_1$ – $M_5$  and  $J_1$ – $J_5$  are model parameters.

Eqs. (1)–(7) were applied to solubility data for some solutes in the binary solvent systems taken from the literature. The details of the systems are given in Table 1.

In Table 2, the constants of Eq. (1) together with its coefficients of determination ( $R^2$ ) and  $F$ -values are shown. For the sake of space, the model constants and statistical parameters of the other equations are not given.

The percent average error of the model predicted solubility with respect to the experimental solubility, %A.E., for each model was calculated by Eq. (8):

$$\%A.E. = 1/Z \sum [100|(X_m)_p - (X_m)_e|/(X_m)_e] \quad (8)$$

where  $Z$  equals the number of data,  $N$ , in each system for models 1 and 3–7 and  $(N - 2)$  for the model 2,  $(X_m)_p$  and  $(X_m)_e$  denote the predicted and experimental values of  $X_m$  at  $f_a$ . The value of %A.E. was an indicator of the accuracy and predictability of the model. The lower the %A.E., the greater the accuracy of the model. The percent overall average error i.e. the sum of %A.E. divided by the total system number, %O.A.E. =  $(\sum \%A.E.)/88$ , and the number of the systems adhered best to a model, judged from the number of the lower %A.E. values, were used for comparison of the models.

Table 1  
Systems used for application of Eqs. (1)–(7)

System No.	Solute in solvent <i>a</i> + solvent <i>b</i>	Reference
1	Anthracene in benzene + cyclohexane	Acree and Rytting (1983)
2	Anthracene in benzene + n-heptane	Acree and Rytting (1983)

%O.A.E	1.95	1.98	3.93	2.47	3.07	3.63	2.17	

*N*, number of data in each system.

In Table 3, the values of %A.E. and %O.A.E. are provided. According to this table, the accuracy of the models with respect to %O.A.E. decreased in the following order: Eq. (1) > Eq. (2) > Eq. (7) > Eq. (4) > Eq. (5) > Eq. (6) > Eq. (3)

Eq. (1) was the most accurate model (%O.A.E. = 1.95) and Eq. (3) was the least accurate (%O.A.E. = 3.93). It can be seen from the above order that when the original Eqs. (3) and (5) were modified to Eqs. (6) and (7), the accuracy was improved. For example, modification of Eq. (5) to Eq. (7) decreased the %O.A.E. from 3.07 to 2.17.

In terms of the number of systems adhered best to a model which could be inferred from Table 3, Eq. (2) was the best followed by Eqs. (7), (5), (1), (4), (3) and (6), respectively.

The analyses given for 88 systems suggested that because of lower percent overall average error, models 1 and 2 were superior to the previous models. In addition, the highest number of systems adhered best to model 2 indicating its suitability.
