

# MINIMAL UNIVERSAL COVERS IN $E^n$

BY  
H. G. EGGLESTON\*

## ABSTRACT

It is shown that any plane set of constant unit width contains a semi-circle of radius  $\frac{1}{2}$ , and using this a minimal universal plane cover is explicitly constructed. It is also shown that in an  $n$ -dimensional space with  $n > 2$  there are minimal universal covers of arbitrary large diameter.

**Introduction.** We shall consider subsets of real  $n$ -dimensional Euclidean space  $E^n$ . Denote by  $\mathcal{K}_n$  that class of subsets of  $E^n$  which have a width in every direction equal to 1. If two subsets  $X$  and  $Y$  of  $E^n$  are congruent we write  $X \sim Y$ .

A subset  $C$  of  $E^n$  is called a *universal cover* if it is closed, convex and such that for every subset  $A$  of  $E^n$  whose diameter is less than or equal to 1 we can find a subset  $B$  of  $C$  such that  $B \sim A$ . Since every such set  $A$  is contained in a member of  $\mathcal{K}_n$ , it is sufficient in proving that a set  $C$  is a universal cover to verify that the congruent subset  $B$  of  $C$  can be found corresponding to every set  $A$  that belongs to  $\mathcal{K}_n$ .

By a *minimal* universal cover is meant a universal cover of which no proper subset is also a universal cover.

In the plane the diameter of any minimal cover is less than 3 and the question has been asked (by V. Klee, see [2]) as to whether there is a finite upper bound of the diameters of compact minimal universal covers in  $E^n$ , depending possibly on  $n$ . We show that this is not the case by proving that for any given positive number  $K$  and any integer  $n$  with  $n \geq 3$ , there is a compact minimal universal cover in  $E^n$  whose diameter is greater than  $K$ .

We first prove that a certain plane set is a minimal universal plane cover by means of a lemma, which incidentally also shows that any set in  $\mathcal{K}_2$  contains a semicircle of radius  $\frac{1}{2}$  (see [1]).

**§1. An explicit example of a plane minimal universal cover.** In this section it is shown that a certain set  $Y$ , defined explicitly, is a plane minimal universal cover.  $Y$  is the union of a disc and of a Reuleaux triangle, both of unit diameter, so

placed that two of the vertices of the triangle are diametrically opposite points on the disc. See Figure 1.

Figure 1

If  $Y$  is a universal cover at all it must be a minimal one: indeed no proper subset of  $Y$  can contain both a disc and a Reuleaux triangle each of unit diameter.

We shall deduce that  $Y$  is a universal cover from the following lemma.

**LEMMA 1.** *If  $Z$  is a plane set of unit constant width then there are two points on the frontier of  $Z$ , say  $s, t$ , which are at unit distance apart and such that of the two semicircles of radius  $\frac{1}{2}$  that pass through both  $s$  and  $t$ , one at least, does not meet the interior of  $Z$ .*

For if this lemma were true then, since every point of  $Z$  is distant at most 1 from both  $s$  and  $t$ , it would follow that  $Z$  lies in a figure bounded by a semicircle on  $st$  and (on the opposite side of  $st$ ) two arcs of unit radius and centers  $s$  and  $t$ . This figure is congruent to  $Y$ . Thus  $Z$  is congruent to a subset of  $Y$ . But any set whose diameter does not exceed 1 is contained in a set of unit constant width. Hence  $Y$  is a universal cover. It remains to prove the lemma.

**Proof of the lemma.** By a standard approximation argument it is sufficient to establish the lemma when  $Z$  is a Reuleaux polygon and in what follows we consider this case only.

Two vertices of  $Z$ , say  $a, b$ , are said to be *opposite* if and only if they are at unit distance apart. In the frontier of  $Z$  lie two circular arcs whose centers are  $a$  and  $b$ . They lie on one and the same side of the line  $ab$ ; we call this the *positive* side and the other side will be called the *negative* side. The circumcircle of the part of  $Z$  on the negative side of  $ab$  will be denoted by  $\gamma_{ab}$ , its radius by  $r_{ab}$  ( $\gamma_{ab}$  is a disc).

In any case  $r_{ab} \geq \frac{1}{2}$  and we wish to establish the existence of two opposite vertices  $a, b$ , for which  $r_{ab} = \frac{1}{2}$ . We assume that no such vertices exist and show that this leads to a contradiction.

Any two vertices  $p, q$  on the frontier of  $Z$  divide this frontier into two arcs.

Moreover, if  $p$  and  $q$  are not opposite, then one of these two arcs contains no points opposite to  $p$  or  $q$ . The vertices of  $Z$  on this arc other than  $p$  or  $q$  are said to lie *between*  $p$  and  $q$ . If  $p$  and  $q$  are opposite then by the vertices between  $p$  and  $q$  we mean those that lie on the negative side of the line  $pq$ .

Since  $r_{pq} > \frac{1}{2}$ , there must, for any pair of opposite vertices  $p, q$ , be vertices between  $p$  and  $q$  which lie on  $\gamma_{pq}$ . Define the vertices  $v, w$  such that they lie on  $\gamma_{pq}$  and no other vertices between  $p$  and  $v$  or between  $q$  and  $w$  lie on  $\gamma_{pq}$ . Let there be  $f(p), g(q)$  vertices between  $p$  and  $v$  and between  $q$  and  $w$  respectively. Let  $h(pq) = \min(f(p), g(q))$  and  $\tau = \min_{p,q} h(pq)$ . Choose opposite vertices  $a, b$  so that  $\tau = h(ab)$  and suppose for definiteness that  $f(a) = h(ab)$ . Then let  $b_1$  be the vertex opposite  $a$  adjacent to  $b$  and  $a_1$  be the vertex opposite to  $b_1$  adjacent to  $a$ .

We consider two cases.

CASE (i)  $\tau = 0$ .

$a_1$  lies on  $\gamma_{ab}$  (see Figure 2).  $b_1$  lies outside  $\gamma_{ab}$  and the line joining  $b_1$  to the center of  $\gamma_{ab}$  bisects internally the angle  $ab_1a_1$ . Hence  $\gamma_{ab}$  cuts the segment  $b_1a_1$

Figure 2

in two points  $a_1$  and  $c$ , and the center of  $\gamma_{ab}$  lies on the positive side of  $a_1b_1$ . Thus the part of  $\gamma_{ab}$  on the negative side of  $a_1b_1$ , apart from the point  $a_1$ , lies interior to  $\gamma_{a_1b_1}$ . But this means that no vertex of  $Z$  on the negative side of  $a_1b_1$  lies on  $\gamma_{a_1b_1}$ . This is impossible since it implies  $r_{a_1b_1} = \frac{1}{2}$ .

CASE (ii)  $\tau > 0$ .

Let  $c$  be the vertex of  $Z$  between  $a$  and  $b$  on  $\gamma_{ab}$  nearest to  $a$  (see Figure 3). Because of the extremal property of  $a, b$  and  $c$  and because  $\tau > 0$ ,  $b, c$  and all the vertices of  $Z$  between  $a_1$  and  $c$  must be interior points of  $\gamma_{a_1b_1}$ . Since  $b, c$  are interior to  $\gamma_{a_1b_1}$ , of the two parts of  $\gamma_{ab}$  on the two sides of the line  $bc$  one must

Figure 3

lie interior to  $\gamma_{a_1 b_1}$ . Since  $a_1$  lies on the frontier of  $\gamma_{a_1 b_1}$  it must be that part of  $\gamma_{ab}$  on the side of  $bc$  opposite to  $a_1$ . Thus all the vertices of  $Z$  between  $b$  and  $c$  are interior to  $\gamma_{a_1 b_1}$ . Hence all the vertices of  $Z$  between  $a_1$  and  $b_1$  are interior to  $\gamma_{a_1 b_1}$ . Again this is impossible.

The lemma 1 is proved.

REMARK. The lemma also shows that any member of  $K_2$  contains a semicircle of radius  $\frac{1}{2}$ . For if  $Z$  is a Reuleaux polygon and in the notation of the lemma  $\gamma_{ab} = \frac{1}{2}$  then all vertices of  $Z$  on the negative side of  $ab$  lie in  $\gamma_{ab}$  and the frontier of  $Z$  on the positive side of  $ab$  (which is formed from circular arcs of radius 1 with centers at these vertices) lies outside or on the frontier of  $\gamma_{ab}$ . Thus of the frontier of  $\gamma_{ab}$  one semicircle lies inside  $Z$  and the other lies outside  $Z$  where inside and outside are to be interpreted in the weak sense; i.e., frontier points of  $Z$  can lie in the frontier of  $\gamma_{ab}$ .

§2. A minimal universal cover in  $E^n$  of large diameter. By a ball is meant a closed solid sphere; for example, a set such as  $\{(x_1, \dots, x_n) \mid \sum_{i=1}^n (x_i - k_i)^2 \leq r^2\}$  where  $(x_1, \dots, x_n)$  denote the coordinates of a point in  $E^n$ .

We need the following lemma.

LEMMA. 2. *There is a member  $W$  of  $\mathcal{K}_n$ ,  $n \geq 3$ , such that the projection of  $W$  in any direction is not an  $(n - 1)$ -dimensional ball.*

Let  $B_0$  be the  $n$ -dimensional ball with center  $(0, 0, \dots, 0)$  and radius  $\frac{1}{2}$ . Let  $B_i$  be the ball with radius 1 and center  $p_i$  where every coordinate of  $p_i$  is zero except the  $i^{\text{th}}$ , and the  $i^{\text{th}}$  coordinate is  $(7^{\frac{1}{2}} - 1)/2^{\frac{3}{2}}$ . Let  $U$  be the intersection of  $B_0$  and all the  $B_i$  and let  $V$  be the union of  $U$  and all the points  $p_i$ . Let  $W$  be a member of  $\mathcal{K}_n$  such that  $W \supset V$ .

Let  $W_\theta$  be the projection of  $W$  in the direction  $\theta$ . By direct calculation it can be seen that there is a point  $f$  on the frontier of  $W_\theta$  which is the projection of a point

of the frontier of  $W$  that lies interior to  $B_0$  and on the frontier of one of the  $B_i$ . But this means that the frontier of  $W_\theta$  in a sufficiently small neighborhood of  $f$  coincides with the frontier of an  $(n - 1)$  dimensional ball of radius 1. Thus  $W_\theta$  is not an  $(n - 1)$  dimensional of radius  $\frac{1}{2}$ . Since  $W_\theta \in \mathcal{X}_{n-1}$  it follows that  $W_\theta$  is not an  $(n - 1)$ -dimensional ball.

**COROLLARY.** *There is a member  $W$  of  $\mathcal{X}_n$  such that the greatest lower bound of the circumradii of projections of  $W$  in all directions is greater than  $\frac{1}{2}$ .*

The proof is obvious by compactness arguments.

**LEMMA 3.** *If  $Z \in K_2$  and every square circumscribing  $Z$  has its sides bisected by the points of contact with  $Z$  then  $Z$  is a circle.*

Let  $a, b$  be two points of  $Z$  distant 1 apart and such that the semicircle  $t_{ab}$  joining them lies in  $Z$ . Let the center of this semicircle be  $p$ , and let  $q$  be one of the points of  $Z$  most distant from  $p$ . The line through  $q$  perpendicular to  $pq$  is a support line of  $Z$ : hence by the hypothesis the support lines of  $Z$  parallel to  $pq$  touch the circle of which  $t_{ab}$  is a part. But then by hypothesis  $pq$  must be equal to  $\frac{1}{2}$ . Hence  $Z$  is a circle.

Denote by  $Z$  that member of  $\mathcal{X}_n$  such that the greatest lower bound of the circumradii of projections of  $Z$  in all directions has the largest possible value. Let this value be  $R$ ; then  $R > \frac{1}{2}$ .

**Construction of a universal minimal cover.** Let  $P$  be the infinite prism  $|x_i| \leq \frac{1}{2}, i = 1, 2, \dots, n - 1, x_n \geq 0$ .  $P$  is a universal cover and our universal minimal cover will be a subset of  $P$ . Denote the projection of any set  $X$  in  $E^n$  onto  $x_n = 0$  by  $X_0$ . Then if  $Y \in \mathcal{X}_n$  and  $Y \subset P$  we have  $Y_0 \in \mathcal{X}_{n-1}$  and  $Y_0 \subset P_0$  where  $P_0$  is the  $(n - 1)$ -dimensional cube whose faces lie in the intersections of the hyperplanes  $x_i = \pm \frac{1}{2}, i = 1, 2, \dots, n - 1$ , with  $x_n = 0$ . Of the  $2^{n-1}$  faces of this cube denote that which lies in  $x_1 = \frac{1}{2}$  by  $F$ .  $Y_0$  meets  $F$  in precisely one point; denote this point by  $F(Y)$ .

Consider the class of sets  $\mathcal{Y}$  congruent to  $Y$  which lie in  $P$  and can be obtained from  $Y$  by combining a rotation or reflection which leaves the line  $x_1 = x_2 = \dots = x_{n-1} = 0$  fixed, with a translation perpendicular to this line. Let  $F(\mathcal{Y})$  be the set of points formed by  $F(Y)$  for all  $Y \in \mathcal{Y}$ . Let  $F^*(\mathcal{Y})$  be the subset of the points of  $F(\mathcal{Y})$  that are most distant from the point  $(\frac{1}{2}, 0, \dots, 0)$  (i.e. the center of face  $F$ ). Both  $F(\mathcal{Y})$  and  $F^*(\mathcal{Y})$  are closed non-void sets. If  $(\frac{1}{2}, x_2, x_3, \dots, x_{n-1}, 0)$  belongs to  $F(\mathcal{Y})$  so do all the  $2^{n-2}$  points  $(\frac{1}{2}, \pm x_2, \pm x_3, \dots, \pm x_{n-1}, 0)$  and they are all the same distance from  $(\frac{1}{2}, 0, 0, \dots, 0)$ . Thus there is a point, say  $(\frac{1}{2}, x_2^*, x_3^*, \dots, x_{n-1}^*, 0)$ , of  $F^*(\mathcal{Y})$  for which  $x_i^* \geq 0$ . Select one such point and let  $Y^*$  be the set (or one of the sets) belonging to  $\mathcal{Y}^*$  such that  $F(Y^*) = (\frac{1}{2}, x_2^*, x_3^*, \dots, x_{n-1}^*, 0)$ . It follows from lemma 3 that  $Y^*$  is the point  $(\frac{1}{2}, 0, 0, \dots, 0)$  if and only if  $Y$  is a ball.

Next let  $g$  be a large positive number so that  $2(R - 1/2) \cdot g > K$  ( $K$  is the preassigned positive number,  $R$  the minimal circumradius of any projection of  $Z$ ), and let  $P_g$  be the intersection of  $P$  with the cone

$$(1) \quad x_1^2 + x_2^2 + \dots + x_{n-1}^2 \leq \frac{(x_n + g)^2}{(2g + 1)^2 - 1}$$

This cone intersects  $x_n = h$  in the  $(n - 1)$ -dimensional ball with center  $(0, 0, \dots, 0, h)$  and radius  $r_h = (h + g) / ((2g + 1)^2 - 1)^{1/2}$ . Since this radius is large for large values of  $h$  it follows that  $P_g$  is a universal cover.

Also the set  $P_g$  contains the  $n$ -dimensional unit ball with center at  $x_n = \frac{1}{2}, x_i = 0, i = 1, \dots, n - 1$ . Denote this ball by  $B^*$ .

For each set  $Y$  of  $\mathcal{X}_n$  in  $P$  select  $Y^*$  as described above and translate  $Y^*$  parallel to the  $x_n$  axis until it lies inside  $P_g$  and, subject to this condition, is as close to  $x_n = 0$  as possible. Let the translated set be  $Y^{**}$ . Let  $Q$  be the union of all these sets and let  $S$  be the convex cover of the closure of  $Q$ .  $Q$  and (therefore)  $S$  are bounded.  $S$  is a subset of  $P_g$  that meets the hyperplane  $x_n = 0$  (since  $Q \supset B^*$ ) and  $S$  also meets the hyperplane  $x_n = K$ . For consider where  $Z^{**}$  can lie. If  $Z^{**}$  lies in  $x_n < K$  then  $R \leq r_K$ , i.e.

$$R \leq (K + g) / ((2g + 1)^2 - 1)^{1/2} ,$$

which implies

$$R \leq \frac{K + g}{2(g + 1)^{1/2}} \leq \frac{K}{2g} + \frac{1}{2} .$$

Thus  $2(R - \frac{1}{2})g \leq K$ . But this contradicts our choice of  $g$ . Thus  $Z^{**}$  lies at least partly in  $x_n \geq K$ . Hence  $S$  lies partly in  $x_n \geq K$ , and the diameter of  $S$  is at least  $K$ .

$S$  is a compact universal cover; let  $T$  be a subset of  $S$  that is a minimal compact universal cover. By the same argument as that above  $T$  contains points in  $x_n \geq K$ . Now the line  $L$  defined by  $x_1 = \frac{1}{2}, x_2 = x_3 = \dots = x_{n-1} = 0$  meets  $Q$  in the single point  $q = (\frac{1}{2}, 0, \dots, 0, \frac{1}{2})$ . Moreover  $q$  is the only point of the closure of  $Q$  on  $L$ . For if this were not so let  $p$  in  $\bar{Q}$  lie on  $L, p \neq q$ . Then there exists a sequence of points  $p_j$  such that  $p_j \in Q$  and  $p_j \rightarrow q$  as  $j \rightarrow \infty$ . Then  $p_j$  belongs to one of the sets of which  $Q$  is the union, say  $p_j \in Y_j^{**}$ . Now  $Y_j^{**}$  meets  $x_1 = \frac{1}{2}$  in a single point, say  $y_j^*$ , and is moreover contained in an  $n$ -dimensional ball of radius 1 touching  $x_1 = \frac{1}{2}$  at  $y_j^*$ . If the distance  $py_j^*$  is  $\tan \theta_j$ , that of  $pp_j$  is greater than or equal to  $\sec \theta_j - 1$ . Since  $p_j \rightarrow p$  as  $j \rightarrow \infty$  it follows that  $\theta_j \rightarrow 0$  as  $j \rightarrow \infty$  and thus  $y_j^* \rightarrow p$  as  $j \rightarrow \infty$ . Let the coordinates of  $y_j^*$  be  $(y_1^{(j)}, y_2^{(j)}, \dots, y_n^{(j)})$ . Since  $p$  has its 2<sup>nd</sup>, 3<sup>rd</sup>, ...,  $(n - 1$ <sup>st</sup>) coordinates all zero this means that  $y_2^{(j)} \rightarrow 0, \dots, y_{n-1}^{(j)} \rightarrow 0$ . Now a subsequence  $\{Y_j\}$  converges to a member, say  $W$ , of  $\mathcal{X}_n$  and  $F^*(W)$  is the single point  $(\frac{1}{2}, 0, 0, \dots, 0)$ . By the remark concerning

Lemma 3,  $W$  must be such that all its two-dimensional projections are circles. Hence  $W$  is an  $n$ -dimensional ball, i.e.,  $W \sim B^*$ . Now  $Y_{j_i}^{**}$  is one of the sets of which  $Q$  is the union and thus  $Y_{j_i}^{**}$  cannot be translated inside  $P_q$  parallel to the  $x_n$  axis so that it lies nearer to  $x_n = 0$ . Thus  $Y_{j_i}^{**}$  meets the surface of the cone (1). Hence so also does  $W$ . Thus in fact  $W$  is  $B^*$ . But if this is so,  $Y_{j_i}^{**}$  converges to  $B^*$ . Hence  $y_{j_i}^{**}$  converges to  $q$  and  $p$  is  $q$ .

This contradiction establishes that the line  $L$  meets  $\bar{Q}$  in the single point  $q = (\frac{1}{2}, 0, \dots, 0, \frac{1}{2})$ .

Now  $S$  is the convex cover of  $\bar{Q}$  and  $\bar{Q}$  lies in the set  $x_1 \leq \frac{1}{2}$ , and if  $x_1 = \frac{1}{2}$ , then  $0 \leq x_i \leq \frac{1}{2}$ ,  $i = 2, \dots, n-1$ , and it follows that  $S$  cannot meet the line  $L$  in any point other than  $q$ .  $T$  is a universal cover and hence contains an  $n$ -dimensional ball of radius  $\frac{1}{2}$ .

$S \subset P$  and it follows that  $S$  meets the line  $L$ . Thus  $T$  contains  $B^*$ . Thus  $T$  contains the point  $(0, \dots, 0)$ . Hence  $T$  has diameter at least equal to  $K$ .

This establishes the required result.
