Comments on Production and Characterization of Aflatoxin B₂ Oximinoacetate

Sir: In an otherwise excellent paper on the chemistry of aflatoxin B₂ oximinoacetate in the March/April 1989 issue of the *Journal of Agricultural and Food Chemistry* K. L. Hastings et al. (1989) perpetuate a misunderstanding about the formation of Schiff bases with amino functions in proteins.

The Schiff base formed by an aldehyde having a hydroxy group α to the carbonyl is susceptible to further prototropic transformation known as the Amadori rearrangement.

This process is well documented for sugars and glyceraldehyde. The Amadori rearrangement also occurs with Schiff bases formed by the 8,9-dihydro-8,9-dihydroxy derivatives of aflatoxin B₁ or via the epoxide or the dichloride (dibromide). The ultimate structure is the result of still further prototropic shifts (Sabbioni et al., 1987). While it is remotely possible that these transformations are induced only in the process of isolation, the evidence argues that a Schiff base is not the actual structure present in a protein that has reacted with aflatoxin B₁ dihydrodiol (or equivalent).

Therefore, in the paper by Hastings et al. (1989) the

structures for the Schiff base conjugate and the dichloride (dibromide) conjugate in Figure 1 are incorrect. The structures of the guanine adduct, which lacks a proton on the N-7 position of guanine, is correct as shown because it cannot undergo further rearrangement.

Registry No. Aflatoxin B₂ oximinoacetate, 118920-31-3.
