#### Abstract

The crystal structure of the major isomer of KIH-6127 was investigated by X-ray crystallographic techniques. The solid state structure and its conformation were confirmed as the E form. Thus KIH-6127 is mainly consistent with methyl 2-[(4,6-dimethoxypyrimidin-2-yl)oxy]-6-[1-E-(methoxyimino)ethyl] benzoate (compound 1: Table 1). Further modifications of the iminoxy moiety to introduce a variety of hal oalkyl, haloalkenyl, and others were made, and the Z isomers of several derivatives were prepared. The physicochemical properties of these derivatives were measured, including their $\log \mathrm{P}$ and $\mathrm{K}_{\mathrm{d}}$ values. We tested their herbicidal activity against barnyard grass and their phytotoxicity to transplanted rice in flooded paddy conditions. We also studied the role of the iminoxy moiety, on the basis of the hypothesis that the difference in the E/Z configurations of the iminoxy moiety determines their biological activity. However, clear differences in the herbicidal activities were not observed between these isomer groups. Each Z isomer was more hydrophilic than its E counterpart. To investigate this finding more intensively in a single $\mathrm{E} / \mathrm{Z}$ pair, the surface area of each E/Z isomer of KIH-6127 was calculated from the X-ray data for the KIH-6127E form. The $Z$ conformation of the iminoxy moiety appears to take a more compact mol ecular conformation, resulting in the Z isomer having more hydrophilic surface area than the corresponding E isomer. QSAR studies focused on the iminoxy moiety. Both pre-and post-emergence activities of the compounds were well correlated with the square of the $\log \mathrm{P}$ value for both configurations of the iminoxy moiety. In other words, these configurations merely contributed to the activity by way of their hydrophilicity. The difference between optimum $\log \mathrm{P}$ values for pre versus post-emergence indicated that the optimum compound is more lipophilic for pre than for post-emergence activity. Phytotoxity against rice also correlated well with the $\mathrm{K}_{\mathrm{d}}$ value. Thus stronger soil adsorption of the compounds provides higher safety for rice. On the basis of those QSAR studies, compound $\mathbf{1}$ was selected as the optimal compound for development as a commercial herbicide.

Keywords: Methyl 2-[(4,6-dimethoxypyrimidin-2-yl) oxy]-6-[1-E-(methoxyimino)ethyl] benzoate; KIH6127; Pyriminobac-methyl; herbicide; barnyard grass; ALS; QSAR

## INTRODUCTION

Methyl 2-[(4,6-dimethoxypyrimidin-2-yl)oxy]-6-[1(methoxyimino)ethyl] benzoate [KIH-6127, Pyrimino-bac-methyl; Figure 1, $\mathbf{1}$; the technical grade is a mixture of the E and $Z$ forms (2), respectively] has been found to be particularly effective herbicide against barnyard grass (Echinochloa oryzicola) over a wide range of growth stages including pre-emergence application. This compound has excellent safety for transplanted rice crops in flooded paddy conditions (Hanai \&t al., 1993). Pyriminobac-methyl was approved in 1996 and was first launched earlier this year as one of the active ingredients of the one-shot rice herbicide Prosper (trade name of Kumiai) in J apan. Compound $\mathbf{1}$ has been proposed to inhibit the plant enzyme acetolactate synthase (ALS), blocking branched chain amino acid biosynthesis (Shimizu et al., 1994).

As reported previously (Tamaru et al., 1997), synthesis of KIH-6127 yields a mixture of two isomers ( $\mathbf{1}$ and 2) in a >9:1 (major/minor) ratio. These isomers have been separated by silica-gel column chromatography,

and their stereochemistry was initially determined by NMR spectrometry. The major isomer was tentatively assigned as being the E isomer (1) (Tamaru et al., 1997). However, we required more precise structural information for compound $\mathbf{1}$ for our project. In this paper, we report results of X-ray crystallography to determine the solid state structure and precise configuration of the 1 -(methoxyimino)ethyl moiety of compound $\mathbf{1 .}$

a Herbicidal activity against E. oryzicola in pre-emergence. ${ }^{b}$ Calculated by the QSAR equations. c Herbicidal activity against E. oryzicola in three-leaf growth stage. ${ }^{d}$ Phytotoxity against O. sativa. ${ }^{e}$ Logarithm of partition coefficient in 1-octanol/water. ${ }^{\text {f }}$ The $K_{d}$ value as soil adsorption. ${ }^{\text {g }} \mathrm{NT}$, not tested.

Structure-activity studies examined the influences of the following moieties on biological activity: 6-alkyl $\left(R^{1}\right)$, ester ( $R^{2}$ ), al koxyimino ( $R^{3}$ ), the bridge atom (X), and the 4,6-disubstituted pyrimidine moieties (A, B, Z) (Figure 2, compound 3) (Tamaru et al., 1997). The results showed that the iminoxy moiety has the dominant effects on biological activity. Changes of the alkyl group in the iminoxy moiety were less influential on biol ogical activity. Thus, changes in the iminoxy moiety offered the most structural flexibility without adversely affecting biological activity.
To investigate the contribution of iminoxy moiety, the QSAR study focused on the iminoxy derivatives including the Z isomers and clarified physicochemical and stereochemical behavior on biological activities.

## MATERIALS AND METHODS

Preparation of Test Compounds. Physical properties of test compounds covered in this paper are given in Table 2. Melting points cited are not corrected. The structures of the compounds were confirmed by NMR along with IR and mass spectroscopy. ${ }^{1} \mathrm{H}$ NMR spectra were obtained on a J EOL J MN-PMX-60si. The solvent used was deuterochloroform unless otherwise noted. ${ }^{1} \mathrm{H}$ chemical shifts are in parts per million ( $\delta$ ) with respect to tetramethylsilane. Test compounds (Figure 2, structure 3; also see Tables 1 and 2 ) were synthesized according to the procedure previously reported (Tamaru et al., 1996, 1997) except compound 16 (Figure 3). The Z isomers were separated and purified by silica-gel column chromatography or high-pressure liquid chromatography (HPLC) as reported (Tamaru et al., 1997). HPLC was carried out on a J ASCO, PU-981/UV-970 with following conditions: the column (octadecylsilica, particle size 120 Å) was $4.6 \times 150 \mathrm{~mm}$ (AM302, YMC); solvent system was acetonitrile/water $=6 / 4(\mathrm{v} / \mathrm{v})$ (sensitivity, 0.02 AuFS); flow rate, $1 \mathrm{~mL} / \mathrm{min}$; column temperature, $35{ }^{\circ} \mathrm{C}$; UV detection, at 245 nm ; injection volume, 10 $\mu \mathrm{L}$ ). Unless otherwise noted, the inorganic chemicals and reagent grade solvents were obtained from Wako and Cica,
and the organic reagents were from Aldrich and Wako. The water used for HPLC was obtained from Milli-RX and Milli-Q systems.

Synthesis of Compounds 16 and 23. Among all test compounds, compound 16 (Figure 3 and Table 1) was obtained in lower yield (12.5\%) along with the undesired $\mathbf{2 3}$ (Figure 3) due to further cydization of $\mathbf{1 6}$. This synthesis used potassium acetate base in methanol at reflux for 1 h or at room temperature overnight (Tamaru et al., 1997). The amount of $\mathbf{2 3}$ gradually increased, depending on the reaction time, despite the presence of unreacted starting material, 21 (Figure 3). Improvement was necessary because 16 was used as the starting material for synthesis of other derivatives.

We initially proposed that such cyclization reactions may be enhanced under base conditions or higher reaction temperatures. However, treatment of 21 without potassium acetate still gave unacceptable formation of 23. After several attempts, we found that some experimental runs without the drying tube gave relatively good yields. Thus the reaction using aqueous hydroxylamine hydrochloride (22) at $5^{\circ} \mathrm{C}$ gave desired 16 in good yield (63\%).

Synthesis of Methyl 2-[(4,6-Dimethoxypyrimidin-2-yl)-oxy]-6-[1-(hydroxyimino)ethyl] Benzoate (16). An aqueous solution of hydroxylaminehydrochloride (22: $19.7 \mathrm{~g}, 0.275$ mol , in 45 mL of water) was added dropwise to a solution of methyl 2-acetyl-6-[(4,6-dimethoxypyrimidin-2-yl) oxy] benzoate (21: $8.3 \mathrm{~g}, 0.25 \mathrm{~mol}$ ) in methanol ( 550 mL ) at $5^{\circ} \mathrm{C}$. The mixture was stirred overnight at $5^{\circ} \mathrm{C}$ and then poured into cold water and extracted with ethyl acetate. The organic layer was washed with water, dried over anhydrous magnesium sulfate, and concentrated in vacuo at $25^{\circ} \mathrm{C}$. The residue was dissolved in a small amount of ethyl acetate and purified by silica-gel column chromatography with hexane + ethyl acetate ( $10+1$ to $6+1$ by volume) as the eluent to give $\mathbf{1 6}$ ( $5.5 \mathrm{~g} ; 63 \%$ yield). NMR chemical shifts and melting points are cited in Table 2.

Selective Synthesis of 8-[(4,6-Dimethoxypyrimidin-2-yl)oxy]-4-methylbenzo[d]oxazin-1-one (23). A suspension of 21 ( $15.1 \mathrm{~g}, 0.0454 \mathrm{~mol}$ ) and $23(4.74 \mathrm{~g}, 0.0681 \mathrm{~mol})$ in methanol ( 200 mL ) was refluxed with stirring for 2 h until

dissolved. During additional heating for 8 h , a white precipitate was gradually observed in the reaction solvent. The reaction mixture was then cooled to room temperature, and the precipitate was filtered and washed with isopropyl ether to give 23 ( $6.5 \mathrm{~g} ; 45.4 \%$ yield); mp 168-170 ${ }^{\circ} \mathrm{C}$. $\left[^{1} \mathrm{H}\right] N M R ~ \delta$ : $2.53(\mathrm{~s}, 1 \mathrm{H}), 3.73(\mathrm{~s}, 1 \mathrm{H}), 5.70(\mathrm{~s}, 1 \mathrm{H}), 7.40-8.07(\mathrm{~m}, 3 \mathrm{H}) \mathrm{ppm}$.

Formulation of Test Chemicals and Preparation of Test Pots. Each test compound was formulated as a 100 g ai/kg wettable powder, containing Emalgen $810\left(5.0 \mathrm{~g} \mathrm{~kg}^{-1}\right.$, 1-octyl-4-polyoxoethyleneoxybenzene, K ao Ltd.), Demolon (5.0 $\mathrm{g} \mathrm{kg}^{-1}$, sodium polymethylnaphthalenesulfonic acid, K ao Ltd.), Kunilite 250 ( $180 \mathrm{~g} \mathrm{~kg}^{-1}$, diatomaceous earth, K unimine Ltd.), Carplex No. 80 ( $60 \mathrm{~g} \mathrm{~kg}^{-1}$, silicon dioxide, Shionogi Co., Ltd.), and Zeeklite (clay).

The wettable powder was diluted with water to the desired concentrations. Plastic pots (square; $100 \mathrm{~cm}^{2}$ in surface area) were filled with paddy soil (clay loam soil: sand $45 \%$, silt $31.1 \%$, and clay $23.9 \%$; organic matter $1.44 \%, \mathrm{pH} 5.6$ ), which was collected locally from a paddy field in Kikugawa, J apan. Unless otherwise noted, the same soil was used in this work. Water was added up to 3 cm in depth to create flooded paddy conditions. The level of flooding water was maintained throughout the test period. Twenty seeds of E. oryzicol a (Ec) were seeded at a depth of 0.5 cm one day after puddling and fertilization. A rice seeding (Oryza sativa, two-leaf growth stage) (Or) was transplanted at a depth of 3 cm in the same pot. One day after seeding for the pre-emergencetest or when Ec reached the three-leaf growth stage for the post-emergence
test, an aqueous sol ution ( 10 mL ) of a wettable powder of the chemicals at the desired dosages was shaken and poured into the pots individually. The test pots were placed in a greenhouse and maintained under the following conditions throughout the experiments: room temperature was maintained at $20-35^{\circ} \mathrm{C}$ and water temperature was maintained at $15-30$ ${ }^{\circ} \mathrm{C}$, under natural daylight conditions.

Evaluation of Biological Activities. The herbicidal symptoms of all test compounds were the same: stunting and slight yellowing. These symptoms are typical for ALS inhibitors (Shimizu et al., 1994). The results of the visual evaluation scores based on these symptoms are well correlated empirically to those based on dry weights. Therefore, we used an empirical visual evaluation method focusing on the stunting symptom. Three weeks after treatment (DAT 21), the herbicidal activity and rice injury ratings were visually evaluated on a percent scale, comparing the herbicidal symptoms of each observed pot with two reference pots which indicated $0 \%$ (= no control or no crop injury) and 100\% (= completely killed). ED 50 values were cal culated as the amounts of active ingredient per hectare ( g ai $\mathrm{ha}^{-1}$ ) required for $50 \%$ of maximum injury to barnyard grass or rice. For the QSAR analysis, the activity of each chemical against barnyard grass and rice is expressed as $I_{50}$ $\left(I_{50}=E D_{50} /\left[M W \times 10^{2}\right]\right)$, i.e., units of molar concentration of active ingredient per are ( M ai $\mathrm{a}^{-1}$ ). QSAR equations were carried out using $\mathrm{pl}_{50}$ ( $\log \left[1 / \mathrm{I}_{50}\right]$; the logarithm of the reciprocal
 (Or) in kg ai $\mathrm{ha}^{-1}$, and $\mathrm{pl}_{50}$ in $\mathrm{mol}^{\mathrm{ai}} \mathrm{a}^{-1}$ ) are cited in Table 1.

${ }^{\text {a }}$ Estimated standard deviations in parentheses.
Structure-Activity Studies. The structure-activity correlation was anal yzed by multiple regression analysis (Fujita et al., 1964), using the TUTORS program (Takahashi et al., 1989). The regression was done stepwise, introducing or withdrawing parameters to minimize the sum of squared deviations. The level of significance of each term was judged by the F-ratio and Student's t-tests.

In our preliminary analysis employing several substituent parameters (i.e., Hansch-Fujita's substituent parameter, $\pi$, and the electronic parameter, $\sigma$, etc.), an indicator variable which represents E/Z configurations was also considered as a descriptor, due to the difficulty of discriminating such stereochemistry by substituent parameter (i.e., each E/Z isomeric substituent pair has the same $\pi$ value). All attempts using such substituent parameters did not gave satisfactory results. Finally we selected the log P (1-octanol/water partition coefficient) and $\mathrm{K}_{\mathrm{d}}$ (soil adsorption coefficient) values (Lambert et al., 1968) which represent the full molecule and which were obtained experimentally.

Measurements of the $\log \mathbf{P}$ and $K_{d}$ Values. The $\log P$ and $K_{d}$ values are listed in Table 1. The $\log P$ values used in this study were obtained experimentally by the shake-flask method (Fujita et al., 1964; OECD, 1989). Soil adsorption coefficients were obtained experimentally as follows: Kikugawa soil (used in biological tests also and described under Preparation of Test Pots) was sieved under 0.5 mm after drying at $80^{\circ} \mathrm{C}$ for 24 h and then at $120^{\circ} \mathrm{C}$ for 24 h at 30 mmHg . The soil ( 6 g , dry weight), with 30 mL of aqueous $\mathrm{CaCl}_{2}\left(10^{-2} \mathrm{M}\right)$ solution containing the test compound at four different concentrations (water solubility (WS) > 10 ppm and compound at $5,2.5,1.25$, and 0.625 ppm or WS $<10 \mathrm{ppm}$ and compound at $0.5 \mathrm{WS}, 0.25 \mathrm{WS}, 0.125 \mathrm{WS}$, and 0.0625 WS ), was shaken at $20{ }^{\circ} \mathrm{C}$ for $16-20 \mathrm{~h}$. After being shaken, each suspension was centrifuged ( 8000 rpm for 20 min ) and the concentration of the compound in the equilibrium solution was measured by HPLC (same conditions described in "Preparation of Test Compounds"). The amount of the compound adsorbed by the soil was obtained from measured concentrations of both the initial and equilibrium solutions.

The soil adsorption coefficient $\left(\mathrm{K}_{\mathrm{d}}\right)$ and adsorption exponent $(1 / n)$ were obtained with the following equation:

$$
\log x / m=\log K_{d}+1 / n \log C_{w}
$$

where $\mathrm{x} / \mathrm{m}$ is the equilibrium concentration of amounts of the compound adsorbed by a unit amount of soil ( $\mathrm{mg} / \mathrm{g}$ ), which is equal to [amount of initially added test compound - amount of test compound in the equilibrium solution]/soil weight, and $\mathrm{C}_{\mathrm{w}}$ is the equilibrium concentration of test compound in the solution phase $(\mathrm{mg} / \mathrm{mL})$.

X-ray Crystallography. Methyl 2-[1-(methoxyimino)-ethyl]-6-[(4,6-dimethoxypyrimidin-2-yl)oxy] benzoate ( $\mathbf{1}$ and $\mathbf{2}$ as $\mathrm{E} / \mathrm{Z}$ mixture in Figure 1) was prepared according to the procedure previously reported (Tamaru et al., 1997). The major isomer, tentatively assumed as E isomer (1), was obtained by recrystallization from a mixture of ethyl acetate and diisopropyl ether. A colorless prism, single crystal of approximately $0.2 \times 0.2 \times 0.3 \mathrm{~mm}^{3}$, was crystallized in the space group $P 2_{1 / a}$ (No. 14), with $a=14.2100 \AA(2), b=7.8590$ $\AA(1), \mathrm{c}=15.9200 \AA(2), \beta=99.4400 \AA(1), \mathrm{Z}=4, \mathrm{D}_{\text {calcd }}=$ $1.368 \mathrm{~g} \mathrm{~cm}^{-3}, \mathrm{~F}_{000}=760.00$, and $\mu(\mathrm{CuK} \alpha)=8.88 \mathrm{~cm}^{-1}$, as monoclinic.

Data collection was performed with an automated diffractometer at room temperature. The number of reflections used for unit cell determination was measured within $2 \theta=(0.0-$ $0.0^{\circ}$ ), with the graphite-monochromated CuK $\alpha$ radiation ( $1=$ $1.54178 \AA$ A). The $\mathrm{R}_{\text {sym }}$ of averaging the equivalent reflections was 0.018 . The Omega scan peak width at half-height is $0.00^{\circ}$.

The structure was solved and resolved by the automatic structure analysis package for the microcomputer, based on MULTAN 78 (Main et al., 1978). The structure was refined by the least squares method. The final R factor (the final agreement value) was 0.068 , including hydrogen atoms.

Computation of Surface Area. The atomic coordinates of the E isomer determined by X-ray crystallography were transformed to the Cartesian coordinates to construct initial atomic coordinates for the computer graphics program. This conformation was used to calculate both MO (Dewar et al., 1985) and surface area (Camilleri et al., 1988).

Unfortunately, recrystallization of the Z isomer suitable for the analysis was unsuccessful due to its lower melting point (melting point of compound $\mathbf{2}$ is $59-60{ }^{\circ} \mathrm{C}$; see Table 2). Therefore, the initial coordinates of the Z isomer were calculated by the following method: The methyl group at the imino moiety of the $E$ isomer (compound 1) was rotated to build $Z$ form temporarily and the optimization of three-dimensional structure of both $\mathrm{E} / \mathrm{Z}$ isomers was cal culated by semiempirical quantum chemical calculations with the AM 1 Hamiltonian of the MOPAC program (Dewar et al., 1985). The surface areas of both E/Z isomers were calculated using the QCPE 413 program. The surface area, final heat of formulation $\left(\Delta \mathrm{H}_{\mathrm{f}}\right)$, and total energy are listed in Table 7.

## RESULTS AND DISCUSSION

X-ray Crystallography. The final positional and thermal parameters for KIH-6127 E form (compound 1) with their estimated standard deviations are listed in Table 3. The calculated bond lengths, bond angles,

and torsion angles of the crystal are listed in Tables 4, 5 , and 6 , respectively. An ORTEP drawing of $\mathbf{1}$ with atomic numbering is cited in Figure 4 . Figure 5 shows the packing mode in the unit cell for $\mathbf{1}$ viewed al ong the b-axis.

The torsion angles about $\mathrm{O}(6)-\mathrm{N}(3)-\mathrm{C}(15)-\mathrm{C}(16)$ [Table 6; $-179.7^{\circ}$ ] were indi cated as the synperiplanar conformation between the methyl group and methoxy group in the iminoxy moiety, which confirmed the configuration of the oxime moiety as E form.

Among other moieties, the torsion angles about C(1)-$\mathrm{C}(2)-\mathrm{O}(3)-\mathrm{C}(9)$ and $\mathrm{N}(2)-\mathrm{C}(9)-\mathrm{O}(3)-\mathrm{C}(2)$ were indi-
cated as $-90.8^{\circ}$ and $175.1^{\circ}$, respectively, and the conformations indicated that the plane of the benzene ring was vertical against that of the pyrimidine ring. This conformation is the result of intermolecular repulsion due to the steric hindrance of the ortho-substituted methoxycarbonyl group. The dihedral angle between the plane of the benzene ring and the plane of the iminoxy moiety is $30^{\circ}$.

These findings clearly confirm compound $\mathbf{1}$ as the E form. Thus, KIH-6127 is mainly methyl 2-[(4,6-di-methoxypyrimidin-2-yl)oxy]-6-[1-E-(methoxyimino)ethyl] benzoate (compound 1).

Stereochemical Aspect of the E/Z Isomers. The activities of compounds having oximino or imino groups and possibly containing at least two isometric structures (such as E/Z forms) were of interest. Several examples were tested, and in specific instances we found that either configuration may provide superior biological activity (Hayakawa et al., 1991; Matsuura et al., 1994). Therefore, the configurational differences between these isomers may determine difference herbicidal activities.

To clarify such different stereochemical behavior, several Z isomers were isolated by chromatography and their herbicidal activities measured (Tamaru et al., 1997).

These Z isomers as well as their corresponding isomers showed high herbicidal activity despite the diversity of their configurations (Table 1). This similarity in activity was unexpected.

To investigate these findings, the physicochemical properties of the Z isomers such as $\log \mathrm{P}$ and the soil adsorption coefficient were measured and compared to their corresponding E isomers (Table 1). The Z isomers show stronger hydrophilic properties and weaker soil adsorption than their counterpart E isomers (Table 1).

In the past decade, the computation of the $\log P$ value from structural information has been pursued by many physical chemists (Hansch and Leo, 1995). The surface area of the molecule (i.e., the water-coated area at which each molecule is covered with a $1.5 \AA$ thick layer representing water) plays an important role as a key factor determining the log $P$ value. The surface area of the molecule also determines other structural properties of the molecule (Camilleri et al., 1988).

To examine the relationship between $\log P$ and the diversity of the configuration of the iminoxy moiety, we calculated the whole surface area of both isomers of KIH-6127 as a typical example. The calculated surface area of the $Z$ isomer is smaller than that of the $E$ isomer as listed in Table 7. It was suggested that the $Z$ configuration of the iminoxy moiety contributes to reduce the surface area of the molecule by taking a more compact molecular conformation. Consequently the $Z$ isomers become more hydrophilic than the corresponding E isomers. The diversity of their configurations merely contributes to the hydrophilicity of the compounds.

Results of QSAR Studies. The fourteen E isomers of KIH-6127 derivatives listed in Table 1 were analyzed to examine the quantitative correlation between their structures and herbicidal activity against barnyard grass in pre-emergence. The QSAR analysis gave eq 1 as

$$
\begin{align*}
\mathrm{PI}_{50}(\text { pre })= & \\
& -0.353(\log P)^{2}+2.151 \log P+0.977 \tag{1}
\end{align*}
$$

Figure 4. ORTEP drawing of KIH-6127-E (1) with atomic numbering.
where $\mathrm{n}=14, \mathrm{~S}=0.223, \mathrm{r}=0.943$, and $\mathrm{F}_{2,11}=44.0$. In this and the following equations, $s$ is the standard deviation, $r$ is the correlation coefficient, and $F$ is the F-test of the correlation with $p$ equal to the number of independent variables in the analysis and q equal to the degrees of freedom ( $q=n-p-1$ ). The figures in parentheses are the $95 \%$ confidence intervals.

Equation 1 shows herbicidal activity to be related parabolically to $\log P$ values of the test compounds. The optimal $\log P$ value obtained from eq 1 is 3.04 . It should be noted that compound 4 (OEt) has the nearest optimum value for $\log \mathrm{P}$. As a result, this value is little larger than that of KIH-6127 which we had selected. The equation also suggests that excessively lipophilic or hydrophilic compounds (beyond the range of between 2 and 4 for $\log P$ values) should have low pre-emergence herbicidal activity. However, the coefficient of the (log $P)^{2}$ term in eq 1 is large, meaning that the effect of changing the $\log \mathrm{P}$ value on the corresponding herbicidal activity is relatively small.

Figure 5. Packing mode in the unit cell for KIH-6127-E (1) viewed along the $b$-axis.

We discussed the stereochemical behavior of the configuration in the iminoxy moiety and then carried out a QSAR analysis including the $Z$ isomers as shown in eq 2.

$$
\begin{align*}
\mathrm{pl}_{50}(\mathrm{pre})= & \\
& -0.358(\log P)^{2}+2.193 \log P+0.884 \\
& (0.071) \tag{0.427}
\end{align*}
$$

Table 7. Calculated Surface Area and Results from the MO Calculation

|  | $E$ form <br> (compound 1) | Z form <br> (compound 2) |
| :--- | :---: | :---: |
| surface area | $343.72 \AA^{2}$ | $329.94 \AA^{2}$ |
| final heat of formation $\left(\Delta \mathrm{H}_{\mathrm{f}}\right)$ | 194.83 kcal | 201.01 kcal |
| total energy | -4964.87 ev | -4964.60 ev |

where $\mathrm{n}=19, \mathrm{~s}=0.214, \mathrm{r}=0.939$, and $\mathrm{F}_{2,16}=59.5$. From the results of both equations, the optimum $\log P$ values are 3.05 and 3.06, and the coefficients of the (log $P)^{2}$ term are 0.353 and 0.358 , respectively. These similarities supported the stability of the equation, even including the Z isomers, and al so our discussions about the stereochemical behavior.

Next, further QSAR analysis was done using $\mathrm{pl}_{50^{-}}$ (post) of the herbicidal activity against barnyard grass at the three-leaf growth stage to obtain eq 3 as

$$
\begin{aligned}
\mathrm{pl}_{50}(\text { post })= & \\
& -0.419(\log P)^{2}+2.262 \log P+0.743 \\
& (0.103)
\end{aligned}
$$

where $\mathrm{n}=15, \mathrm{~s}=0.252, \mathrm{r}=0.943$, and $\mathrm{F}_{2,12}=48.2$. Similarly to eq 2, eq 3 shows herbicidal activity to be related to the square of the $\log P$ values of the compounds. The optimal $\log P$ value obtained from eq 3 was 2.69 and smaller than that of eq 2. This suggested that a more hydrophilic compound is desirable for herbicidal activity against barnyard grass at the threeleaf growth stage rather than at pre-emergence application.

Because the coefficients of the $(\log P)^{2}$ terms in eqs $1-3$ are relatively large compared to log $P$ coefficients, the effects of changing $\log P$ on herbicidal activity are rather small.

In Table 1, the deviation between the minimum activity of pre-emergence and the maximum phytotoxicity is $1.78\left[\Delta \mathrm{pl}_{50}=\mathrm{pl}_{50}(\mathrm{pre})_{\text {min }}-\mathrm{pl}_{50}(\text { rice })_{\max }=3.65\right.$ $-1.87]$. The derivatives listed here show a selectivity greater than 10 times for barnyard grass over rice. The QSAR of the phytotoxicity against rice was carried out. Finally eq 4 was obtained after the preliminary analysis as

$$
\begin{equation*}
\mathrm{pl}_{50}(\text { rice })=-0.366 \mathrm{~K}_{\mathrm{d}}+2.164 \tag{4}
\end{equation*}
$$

(0.121)
where $\mathrm{n}=12, \mathrm{~s}=0.156, \mathrm{r}=0.906$, and $\mathrm{F}_{1,10}=45.4$. In eq 4, the soil adsorption coefficient $K_{d}$ is taken as a fixed parameter. The phytotoxicity toward rice is inversely proportional to the $K_{d}$ value.

Compound 1 was selected as the candidate for commercialization as a novel barnyard grass herbicide with a characteristics well balanced for pre-emergence activity, high-leaf growth stage activity, and acceptable safety.

## ACKNOWLEDGMENT

We express our thanks to Professor Nobuo Tanaka, Tokyo Institute of Technology, for his X-ray crystallographic experiments and many helpful suggestions for the results and manuscript.
