The development of modern gene technologies allows for the expression of recombinant proteins in non-native hosts. Diversity in translational and post-translational modification pathways between species could potentially lead to discrete changes in the molecular architecture of the expressed protein and subsequent cellular function and antigenicity. Here, we show that transgenic expression of a plant protein (α -amylase inhibitor-1 from the common bean (*Phaseolus vulgaris* L. cv. Tendergreen)) in a non-native host (transgenic pea (*Pisum sativum* L.)) led to the synthesis of a structurally modified form of this inhibitor. Employing models of inflammation, we demonstrated in mice that consumption of the modified α AI and not the native form predisposed to antigen-specific CD4⁺ Th₂-type inflammation. Furthermore, consumption of the modified α AI concurrently with other heterogeneous proteins promoted immunological cross priming, which then elicited specific immunoreactivity of these proteins. Thus, transgenic expression of non-native proteins in plants may lead to the synthesis of structural variants possessing altered immunogenicity.

KEYWORDS: α -Amylase inhibitor; transgenic plant; animal model; Th2 inflammation; mass spectrophotometry

INTRODUCTION

Genetically modified (GM) plants are designed to enhance agronomic productivity or product quality and are being increasingly employed in both agricultural and livestock industries (1, 2). Recently, peas (*Pisum sativum* L.) expressing a gene for α -amylase inhibitor-1 (α AI) from the common bean (*Phaseolus vulgaris* L. cv. Tendergreen) were generated to protect the seeds from damage by inhibiting the α -amylase enzyme in old world bruchids (pea, cowpea, and azuki bean weevils) and are currently undergoing risk assessments (3–6).

The present study was initiated to (1) characterize the proteolytic processing and glycopeptide structures of α AI when transgenically expressed in peas (pea- α AI) and (2) evaluate in an in vivo model system the immunological consequence of oral consumption of pea- α AI. We demonstrate that expression

of α AI in pea leads to a structurally modified form of this inhibitor. Employing experimental models, we show that the structural modification can lead to altered antigenicity. These investigations reveal that expression of proteins in non-native hosts can lead to the synthesis of a protein variant with altered immunogenicity.

MATERIALS AND METHODS

Nontransgenic and Transgenic Plants. Seed meal was obtained from nontransgenic peas, genetically modified peas expressing bean α -amylase inhibitor-1 (α AI) (5), genetically modified narrow leaf lupin (*Lupinus angustifolius* L.) expressing sunflower seed albumin protein (SSA) in the seeds (SSA-lupin) (7), and from nontransgenic Pinto bean. Seeds were ground into fine flour in liquid N₂ using a mortar and pestle. This seed meal was then suspended in PBS (0.166 g meal/mL), homogenized, sieved through a 70 μ m mesh, and stored at –70 °C. In some experiments, seed meal homogenates were cooked at 100 °C for 30 min before administration to mice (indicated in text).

Purification of SSA from Transgenic Lupin and α AI from Common Beans and from Transgenic Peas. α AI was purified from the common beans (Pinto and Tendergreen) and transgenic peas and SSA from genetically modified narrow leafed lupin (SSA-lupin) as previously described (7, 8). Purified proteins were analyzed by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE, 15–

25% gradient, 1 mm thick, mini-gel format) and MALDI-TOF mass spectrometry.

Western Immunoblot Analysis. α AI polypeptide composition was determined in protein extracts from common bean and transgenic peas as previously described (3). Protein was extracted from seeds with 0.5 M NaCl, 1 mM EDTA, and 0.1 M *N*-tris(hydroxymethyl)methylaminoethanesulfonic acid at pH 7.8. Aliquots of reduced protein (20 μ g by Bradford assay) were fractionated by SDS-PAGE and electroblotted onto nitrocellulose membrane. α AI polypeptides were detected with an α AI antiserum from rabbit and goat anti-rabbit IgG conjugated to alkaline phosphatase (3). The concentration of α AI in transgenic peas was determined as 4% of total protein as previously described (3).

Structural Analysis of Purified α AI from the Pinto and Tendergreen Beans and from Transgenic Peas. Purified α AI from the common beans, Pinto and Tendergreen, and from transgenic peas were analyzed by matrix-assisted laser desorption/ionization-time-of-flight-mass spectrometry (MALDI-TOF-MS). The proteins were dissolved in water (approximately 1 μ g/ μ L), and then 1 μ L was mixed with 1 μ L of matrix solution (saturated sinapinic acid in 50% acetonitrile/0.1% trifluoroacetic acid) on the sample plate of a Voyager Elite MALDI-TOF mass spectrometer (PerSeptive Biosystems) and allowed to dry. Spectra were collected in linear mode with myoglobin used for close external calibration (Sigma, Cat. No. M-1882, 16952.6 [M + H]⁺, 8476.8 [M + 2H]²⁺).

Mice and Intragastric Administration of Seed Meal from Nontransgenic and Transgenic Plants. BALB/c mice were obtained from specific pathogen-free facilities at the Australian National University. Mice were intragastrically administered 250 μ L of seed meal suspension (~100 mg/mL) containing either transgenic peas, nontransgenic peas, SSA-lupin, or Pinto bean twice a week for 4 weeks. In some experiments, serum was taken from the mice at the start of the third and fifth weeks during feeding. The serum antibody titers were determined as previously described (9).

Mice and Delayed Type Hypersensitivity Responses. BALB/c mice were administered seed meal as described above. Seven days following the final intra-gastric challenge, mice were subcutaneously injected with 25 μ L of the appropriate antigen [Tendergreen- α AI, pea α -AI, or lupin SSA (1 mg/mL in PBS)] into the footpad. The positive control [(+) control] is mice immunized by i.p. injection of 200 μ L containing 50 μ g of Tendergreen- α AI dissolved in PBS with Alum (1 mg/mL) and subsequently receiving 25 μ L of purified Tendergreen- α AI (1 mg/mL PBS). The negative control [(-) control] is mice immunized by i.p. injection of 200 μ L containing 50 μ g of Tendergreen- α AI dissolved in PBS with Alum (1 mg/mL) and subsequently receiving 25 μ L of PBS. DTH responses were assessed by measuring the specific increase in footpad thickness using a digmatic calliper (Mitutoyo, Kawasaki, Japan) 24 h following the challenge. Serum was collected on day 14, and antibody titers were determined as previously described (9).

Murine Model of CD4⁺ Th2 Cell-Mediated Inflammation. BALB/c WT mice were administered seed meal as indicated in the text. Seven and nine days following the final intra-gastric challenge, mice were anesthetized with an intravenous injection of 100 μ L of Saffan solution (1:4 diluted in PBS). Mice were intubated with a 22 gauge catheter needle, through which purified α AI from Tendergreen bean or transgenic pea (1 mg/mL PBS), or vehicle control (PBS), was instilled. Airway responsiveness (AHR), mucus production, and eosinophilia were measured 24 h following the final intra-tracheal challenge. AHR to methacholine was assessed in conscious, unrestrained mice by barometric plethysmography, using apparatus and software supplied by Buxco (Troy, NY) as previously described (9). This system yields a dimensionless parameter known as enhanced pause (Penh), reflecting changes in waveform of the pressure signal from the plethysmography chamber combined with a timing comparison of early and late expiration, which can be used to empirically monitor airway function. Measurements were performed as previously described (9). Lung tissue representing the central (bronchi-bronchiole) and peripheral (alveoli) airways was fixed, processed, and stained with Alcian Blue-PAS for enumeration of mucin-secreting cells or Charbol's chromotrope-Haematoxylin for identification of eosinophils as previously described (9).

Intragastric Administration of Purified α AI and OVA. Mice were administered 200 μ L of affinity purified Tendergreen- or transgenic pea- α AI (5 μ g) with ovalbumin (OVA, 1 mg/mL) in a PBS suspension three times a week for 2 weeks. One week following feeding, the mice were intubated with a 22 gauge catheter needle, through which 25 μ L of OVA (1 mg/mL PBS), or vehicle control (PBS), was instilled and the CD4⁺ Th2-inflammation indices determined as described above. Serum was taken from the mice 1 day after the final intra-tracheal challenge, and serum antibody titers were determined as described (9).

Antigen Specific CD4⁺ T-Cell Response. Peribronchial lymph nodes (PBLN) were subjected to pea- α AI or α CD3/ α CD28 stimulation as previously described (9). In brief, 5 \times 10⁵ PBLN cells/mL were cultured with α AI (50 μ g/mL) or α CD3 (5 μ g/mL)/ α CD28 (1 μ g/mL) for 96 h. IL-4, IL-5, IFN γ levels were determined in supernatants from stimulated PBLN homogenates by using the OptEIA Mouse IL-4, IL-5, and IFN γ kits (Pharmingen).

Statistical Analysis. The significance of differences between experimental groups was analyzed using Student's unpaired *t*-test. Values are reported as the mean \pm SEM. Differences in means were considered significant if *p* < 0.05.

RESULTS

MALDI-TOF-MS Analysis of α AI. To assess the consequences of transgenic expression of the bean α AI in peas, we initially performed a structural analysis of the transgenically expressed protein (pea- α AI). Pea- α AI was compared by Western blot analysis and MALDI-TOF-MS with natively expressed α AI from the common beans, cvs. Pinto (Pinto- α AI) and Tendergreen (Tendergreen- α AI) (collectively termed bean- α AI). Previous studies have shown that bean- α AI is synthesized as a pre-pro- α AI polypeptide that is cleaved following Asn⁷⁷ to form two peptide chains (α and β), both of which are glycosylated and have one or more amino acid residue(s) removed from their C-termini (8). This post-translational processing results in major forms of the α and β chains with masses of 11 646 and 17 319, respectively, and minor forms containing alternative glycans (10–12). Western immunoblot analysis of Tendergreen- α AI and pea- α AI revealed immunoreactive bands in the 11 000–18 000 mass range consistent with the reported structure (10–13). Detailed comparison of Tendergreen- α AI with pea- α AI revealed differences in the banding profile, suggesting possible differences in the molecular structure of natively and transgenically expressed α AI (Figure 1A).

To better resolve the differences between pea- α AI and bean- α AI, affinity purified α AI was analyzed by MALDI-TOF-MS (Figure 1B). The mass spectra of Tendergreen- α AI and Pinto- α AI closely matched a previously published spectrum (10) of a bean- α AI (*Phaseolus vulgaris* L. cv. Greensleeves) confirming that both Tendergreen- and Pinto- α AI possess similar well-characterized post-translational modifications and very similar relative abundance of minor processing variants (10, 11). Alignment of our spectra with the previously published data (10) allowed identification of peaks in the pea-, Tendergreen-, and Pinto- α AI spectra. The major form of the α -chain (11 646 Da) of bean- α AI contains residues 1–76 by cleavage of the pro-protein following Asn⁷⁷, removal of Asn⁷⁷, and the addition of sugar residues (Man₆GlcNAc₂ at Asn¹² and Man₉GlcNAc₂ at Asn⁶⁵). Minor forms of the α -chain of bean- α AI differed by having one to three fewer mannose residues resulting in a series of peaks in the MALDI-TOF spectrum that differ by 162 mass units. In contrast, less heavily glycosylated forms dominated for the α -chain of pea- α AI. In particular, an α -chain with two fewer mannose residues (11 322 Da) was the most abundant for pea- α AI but the least abundant for Tendergreen- α AI (Figure 1C(i)). A further difference in the pea- α AI spectrum was a series of minor peaks differing from the main α -chain peaks by either

Figure 1. The masses of standard proteins are indicated. **(B)** Aligned MALDI-TOF mass spectra of purified α AI from transgenic pea and the common beans, Tendergreen and Pinto. **(C)** Detail from the spectra in panel B showing the regions of the α -chain (i) and the β -chain (ii).

+98 or -64 mass units, indicating another modification of some of the pea- α AI α -chains (**Figure 1C(i)**).

The major form of the β -chain of Greensleeves- α AI (16527 Da) contains residues 78–216 by cleavage of the pro-protein following Asn⁷⁷, the removal of the seven C-terminal residues following Asn²¹⁶, and the addition of sugar residues (Man₃-GlcNAc₂Xyl₁ at Asn¹⁴⁰) (10–13). The β -chain region of the Tendergreen- α AI spectrum closely aligned with that of Greensleeves- α AI (**Figure 1C**). The β -chain region of the Pinto- α AI

spectrum also closely resembled that of Greensleeves- α AI except that both major and minor peaks of Pinto- α AI were shifted by approximately +104 mass units. This mass discrepancy is consistent with five amino acid residue differences between the β -chains of Tendergreen- α AI and Pinto- α AI as predicted by gene sequence comparison (see Supporting Information Figure 1). Further, there are also three predicted residue differences between the Tendergreen- α AI and Pinto- α AI α -chains that result in a difference of +1 mass unit, which would not be

detected by our methods. These sequence differences are consistent with previous reports of α AI polymorphisms among bean cultivars (12, 13). The pea- α AI spectrum showed major peaks corresponding to the two major and minor forms of the β -chain found in Tendergreen- α AI; however, the pea- α AI spectrum also showed a number of other peaks (Figure 1C(ii)). DNA sequencing of the transgene in pea and comparison with the published sequence (14) confirmed that the nucleotide sequences were identical, establishing that the observed further forms of the pea- α AI are related by variations in post-translational modifications including glycosylation (Figure 1C(ii)).

Analysis of the spectra of pea- and bean- α AI also revealed several other differences. First, a number of peaks at \sim 8–9000 and 5824 mass units and below were observed in the bean- α AI spectrum, which are consistent with a previously reported protein that copurifies with bean- α AI (10) and doubly charged ($(MH_2)^{2+}$) forms of the α -chain, respectively. Further, a peak at 4223 mass units was detected in the pea- α AI spectrum, which has not been previously reported. While this peak is barely detected in the bean- α AI spectrum presented here, the peak was observed in a number of other bean- α AI preparations (results not shown). The mass of this peak is consistent with the first 39 residues of the β -chain, which could be obtained by cleavage following an Asn residue, the same protease specificity that provides the reported processing of α AI at Asn⁷⁷. Consistent with this hypothesis, a small peak was detected in some preparations at about 12 304 mass units that could correspond to the remainder of the β -chain.

While pea- α AI has not yet been characterized as thoroughly as the bean- α AI, it is clear that the transgenic expression of the bean α AI gene in the pea led to differences of glycosylation and possibly other differences in both the α - and the β -chains.

Immunological Consequence of Oral Consumption of Beans. Peas are used as a feed component in the livestock industry and also in human diets. Generally, dietary protein antigens undergo gastric digestion leading to the formation of nonimmunogenic peptides and the induction of a state of specific immunological unresponsiveness termed oral tolerance (15, 16). However, the demonstration of structural differences between the transgenic α AI in pea and the natively expressed bean forms raised the concern that the tolerance mechanism may be perturbed, possibly leading to enhanced immunoreactivity.

The induction of oral tolerance results in the failure of the immune system to elicit an active immune response to subsequent exposure to the same antigen in the skin (delayed type hypersensitivity [DTH] response) or lung (CD4⁺ T-helper [Th₂] cell-mediated inflammation). To examine potential differences in immunological responsiveness following oral consumption, mice were fed Pinto bean, which expresses a native form of α AI and subsequently received purified Tendergreen- α AI in the skin and lung. Most varieties of common beans such as Red Kidney or Tendergreen contain high levels of phytohemagglutinin (PHA), an anti-nutritional factor that induces dietary toxicity in rodents and birds. We therefore used the Pinto variety that contains very low levels of PHA (17, 18) as the appropriate control for oral exposure. Oral consumption of native uncooked Pinto bean seed flour followed by intra-tracheal (i.t.) challenge with Tendergreen- α AI or phosphate buffered saline (PBS) failed to induce an α AI-specific IgG₁ antibody response (Figure 2A). Similarly, sub-cutaneous (s.c.) challenge of the footpad or i.t. challenge of Pinto bean-fed mice with Tendergreen- α AI also failed to promote a DTH response (results not shown) or a pulmonary Th₂-inflammatory response [pulmonary eosinophilia, mucus hypersecretion, and enhanced AHR to a bronchocon-

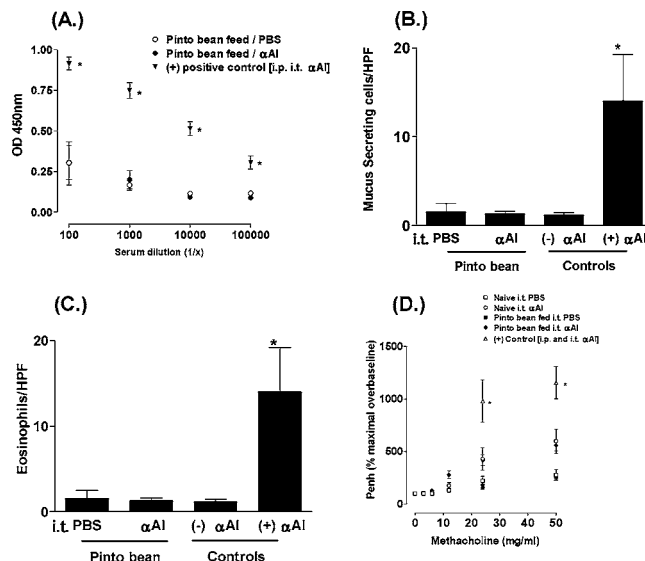

Figure 2. Experimental consumption of bean (cv. Pinto) seed meal does not predispose to inflammation. (A) α AI-specific IgG₁ in serum and (B) mucus-secreting cell numbers and (C) eosinophil levels in lung tissue from Pinto bean-fed mice i.t. challenged with PBS or Tendergreen- α AI. (D) AHR in Pinto bean-fed mice i.t. challenged with PBS or Tendergreen- α AI. strictive agents], respectively (Figure 2B–D). While the level of AHR in the Pinto bean-fed α AI-challenged mice was higher than PBS-challenged mice, the level of responsiveness is not significantly different from that of naïve mice i.t. challenged with Tendergreen- α AI (Figure 2D). As a positive control, mice were sensitized by intra-peritoneal (i.p.) injection and subsequently challenged via the airways with bean-derived α AI to induce immunological responsiveness (Figure 2A–D). Collectively, these data showed that oral consumption of the native bean form of α AI followed by respiratory exposure to bean- α AI did not promote immunological responsiveness or inflammation.

Immunological Consequence of Oral Consumption of Transgenic Peas. To determine whether oral consumption of the transgenic α AI (from pea) elicited an immunological response, mice were orally administered transgenic pea seed meal and α AI; serum antibody titers and DTH responses were examined. Interestingly, in mice that were fed transgenic pea, but not nontransgenic pea, α AI-specific IgG₁ was detected at 2 weeks and at significant levels after 4 weeks of oral exposure (Figure 3A). Consistent with the antibody findings, mice fed nontransgenic pea seed meal did not develop DTH responses following footpad challenge with purified pea- α AI (Figure 3B). In contrast, mice fed transgenic pea seed meal exhibited a significant DTH response as compared to the nontransgenic pea exposed group when purified pea- α AI was injected into the footpad (Figure 3B). As a control for any general effect of genetic modification, we repeated the experiment with material from two other genetically modified plants, lupin (*Lupinus angustifolius* L.) expressing sunflower seed albumin (SSA) [transgenic lupin] (9) and chickpeas (*Cicer arietinum* L.) expressing bean derived α AI. Mice were orally administered lupin or transgenic lupin or chickpea or transgenic chickpea seed meal and subsequently footpad challenged with SSA or α AI and DTH responses were examined. In contrast to transgenic pea, mice fed transgenic lupin or chickpea did not develop

(D–G) $\times 400$ magnification.

DTH responses following footpad challenge with the transgenically expressed and purified SSA or α AI protein (Figure 3B; results not shown). Thus, consumption of transgenic pea containing α AI promoted α AI-specific immunological responsiveness.

To characterize the type of immune response elicited against pea- α AI following oral consumption of transgenic pea, we employed a well-characterized murine model of CD4⁺ Th₂ cell-

mediated inflammation (19). Mice were orally administered transgenic pea seed meal and subsequently i.t. challenged with purified pea- α AI, and key features of Th₂-inflammation [pulmonary eosinophilia, mucus hypersecretion, and AHR] were examined. I.t. challenge of nontransgenic pea-fed mice with purified pea- α AI failed to induce features of Th₂-inflammation (Figure 4A–G). Furthermore, airways responsiveness to the cholinergic spasmogen, methacholine, was not induced in these

Figure 5. Consumption of transgenic pea seed meal predisposed to CD4⁺ T-cell derived Th₂-type cytokine production. IL-4 (A), IL-5 (B), and IFN γ (C) levels in supernatants from α CD3/ α CD28 or pea- α AI or media alone stimulated PBLN cells from nontransgenic and transgenic pea-fed mice i.t. challenged with α AI from pea. Data are expressed as the mean \pm SEM from 3 to 6 mice per group from duplicate experiments. Statistical significance of differences ($p < 0.05$) was determined using Student's unpaired *t*-test.

mice (Figure 4H). However, instillation of pea- α AI into the lungs of mice fed transgenic pea induced key features of Th₂-type inflammation including pulmonary eosinophilia, mucus hypersecretion, and AHR (Figure 4A–H).

Pulmonary eosinophilia, mucus hypersecretion, and AHR are critically linked to the effector function of the Th₂ cytokines (20). To examine whether consumption of transgenic pea promoted a α AI-specific CD4⁺ Th₂-type T-cell response, CD4⁺ T-cells in peribronchial lymph node (PBLN) cultures from mice fed nontransgenic pea or transgenic pea seeds challenged with pea- α AI were stimulated with pea- α AI and cytokine profiles determined. Stimulation of CD4⁺ T-cells in peribronchial lymph node (PBLN) cultures from nontransgenic pea-fed mice challenged with pea- α AI did not elicit Th₂ (interleukin (IL)-4 and IL-5)- or Th₁-type (gamma interferon, IFN γ) cytokine production in response to pea- α AI stimulation (Figure 5A–C). By contrast, stimulation of PBLN cultures with pea- α AI from i.t. challenged mice fed transgenic pea resulted in the significant production of Th₂ cytokines (Figure 5A–C). Thus, oral exposure of mice to transgenic pea, but not nontransgenic seed meal, predisposed to systemic immunological responsiveness characterized by a Th₂-type immune profile.

Pea- α AI Promotes Immune Responses to Other Oral Antigens. Previous investigations have demonstrated that various plant-derived proteins such as tomatine possess immunomodulatory activity and potentiate and polarize immune responses (21–23). We have demonstrated that consumption of transgenic pea in the presence of a large number of potential dietary antigens in the gastrointestinal tract induces an active systemic Th₂-immune response against pea- α AI. In light of these findings, we were next interested in determining whether consumed pea- α AI possessed immunomodulatory activity for Th₂ immune responses and could sensitize mice to heterogeneous nongenetically modified food antigens. Thus, we intra-gastrically (i.g.) administered purified Tendergreen- or pea- α AI with the well-characterized dietary antigen, chicken egg white protein OVA, or OVA alone and subsequently i.t. challenged mice with OVA. I.g. administration of OVA alone did not systemically sensitize mice to OVA (Figure 6A). Further, subsequent OVA challenge in the airways did not promote Th₂-inflammation (mucus hypersecretion, pulmonary eosinophilia, or AHR). Similarly, i.g. administration of bean- α AI and OVA did not systemically sensitize mice or predispose to Th₂-inflammatory processes. However, consumption of pea- α AI and OVA promoted a strong OVA-specific Th₂-type antibody

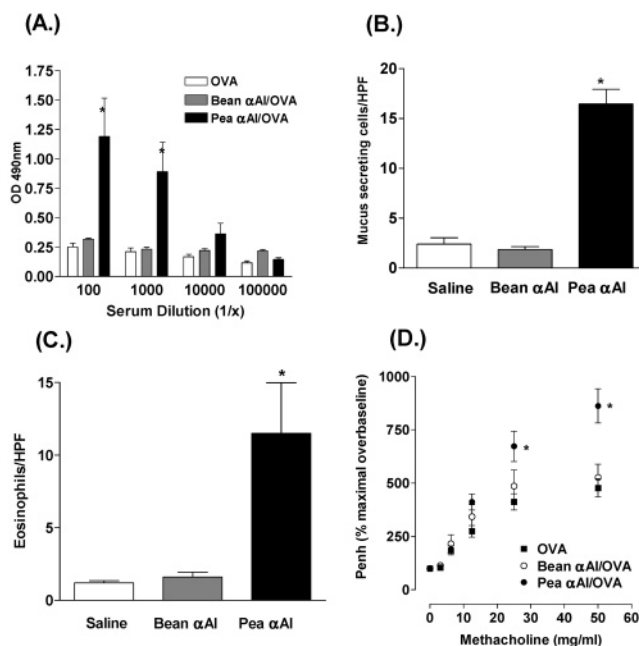

Figure 6. Intra-gastric administration of α AI from pea induces cross-priming of heterogeneous food antigens. OVA-specific IgG₁ levels (A) and the Th₂-inflammation phenotype (mucus hypersecretion) (B), pulmonary eosinophilia (C), and airways hyperreactivity (D) in mice that were fed (i.g. challenged) ovalbumin (OVA) alone (the control) or in combination with natively expressed Tendergreen bean- α AI or transgenically expressed (pea) α AI and subsequently intra-tracheal challenged with purified OVA. Data are expressed as the mean \pm SEM from 4 to 6 mice per group. * $p < 0.05$ as compared to OVA and bean α AI/OVA.

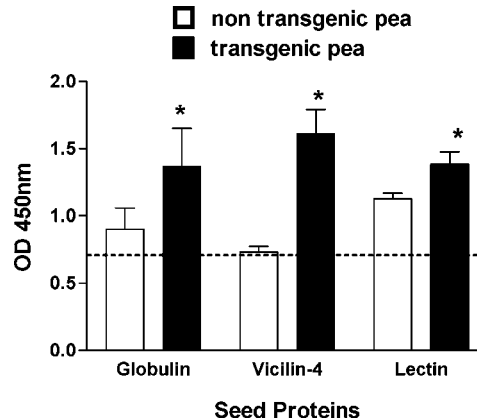

Figure 7. α AI from pea induces cross-priming of pea proteins. Pea globulin-, vicilin-4, and lectin-specific IgG₁ levels in serum from mice that were intragastrically administered 250 μ L (~100 mg/mL) of either nontransgenic or transgenic pea seed meal twice a week for 4 weeks. Data are expressed as mean \pm SEM from 4 to 5 mice per group. * $p < 0.05$ as compared to nontransgenic pea.

response (Figure 6A) and predisposed mice to OVA-induced Th₂-inflammation (Figure 6B–D). To support this observation, we examined serum levels of antigen-specific IgG₁ against pea seed proteins (pea globulins, lectin, and vicilin-4) in transgenic pea and nontransgenic pea-fed mice. Interestingly, levels of antigen-specific IgG₁ against pea globulins, lectin, and vicilin-4 in serum of transgenic pea fed mice were significantly higher than those of nontransgenic pea-fed mice, suggesting a heightened immune responsiveness to dietary proteins due to pea- α AI (Figure 7). Thus, these studies demonstrate that modified α AI possesses immunomodulatory activity and that consumption

of the modified α AI concurrently with heterogeneous proteins can promote immunological cross priming, which predisposes to specific immunoreactivity to these proteins.

DISCUSSION

Recently, peas expressing a gene for α AI from the common bean were generated for protection against field and storage pests (3–6). Characterization of α AI by structural analysis has demonstrated that transgenic expression of this protein in peas led to the synthesis of a modified form of α AI. Further, we show that the modified form of α AI possessed altered antigenic properties and consumption of this protein by mice predisposed to α AI-specific CD4⁺ Th₂-type inflammation and elicited immunoreactivity to concurrently consumed heterogeneous food antigens.

Bean- α AI undergoes significant post-translational modification including variable glycosylation and proteolytic processing leading to the synthesis of a mature functional protein (8, 11). We demonstrate that differences in glycosylation and/or other modifications of the pea- α AI lead to altered antigenicity. Consistent with our observations, investigators have previously demonstrated that differential glycosylation of subunits of a cereal α -amylase-inhibitor family (unrelated to legume α AIs) enhances IgE-binding capacity (24). Moreover, glycosylated cereal α AI subunits have been shown to possess significantly enhanced IgE-binding affinity when compared to the unglycosylated forms (24). These cereal proteins possess identical amino acid sequences and only differ in their carbohydrate moieties, indicating that glycosylation can confer IgE-binding capacity and Th₂-inflammation. In particular, recent investigations have demonstrated that glycan side chains linked to high mannose-type N-glycans on plant-derived glycoproteins can confer immunogenicity and are IgE binding determinants (25, 26). Moreover, α (1,3)-fucose and β (1,2)-xylose linkage to high mannose-type N-glycans (Man₃GlcNAc₂–Man₉GlcNAc₂) promote immunogenicity and IgE binding. The β -chain of pea- α AI possesses β (1,2)-xylose linked high mannose-type N-glycans, and other complex glycoforms and the α -chain may possess an as yet undefined glycoform variant, and it remains to be determined how these modifications alter pea- α AI immunogenicity.

Functional and structural properties of pea- α AI may contribute to its ability to circumvent immune tolerance and elicit inflammatory responses. Bean- α AI is a potent inhibitor of human α -amylase activity and can induce gastrointestinal dysfunction (27). Comparison of bean- and pea-derived α AI activity revealed no difference in enzymatic activity between the two proteins (results not shown). Furthermore, we examined the gastrointestinal tract of pea and transgenic pea-fed mice and observed no histological abnormalities to the gastrointestinal tissue in either group (results not shown). Bean- α AI is also a heat-stable protein and partially resistant to proteolytic degradation (28, 29). Extensive boiling (100 °C for 20 min), while significantly reducing α -amylase inhibitory activity, failed to alter the ability of the transgenic pea to prime for Th₂-inflammation when challenged in the lung [results not shown: see Supporting Information Figure 2]. These findings are consistent with previous demonstrations that cooking of plant material such as lentils and peanuts does not diminish the allergenic potential of certain proteins (30, 31). Furthermore, these studies suggest that the altered immunogenicity of α AI is unrelated to its properties as an amylase inhibitor.

We demonstrate that the immune response elicited against pea- α AI following oral consumption of transgenic pea is

characterized by CD4⁺ Th₂ cell-mediated inflammation, in particular, the presence of IL-4 and IL-5. To examine whether the immune response was dependent on IL-5 and eosinophils, we employed IL-5 and eotaxin-deficient mice. IL-5/eotaxin-deficient mice were i.g. administered nontransgenic and transgenic seed meal and subsequently i.t. challenged with purified α AI. We show that i.t. challenge of transgenic pea fed IL-5/eotaxin-deficient mice induced Th₂-inflammation that was significantly elevated over nontransgenic fed mice (32). These investigations suggest that the immune response elicited against pea- α AI following oral consumption of transgenic pea is not dependent on IL-5 and eosinophils.

In this study, we have demonstrated that transgenic expression of α AI in a pea can lead to the synthesis of a modified form of the protein with altered antigenic properties. Furthermore, we show that concomitant exposure of the gastrointestinal tract to modified α AI and heterogeneous food antigens cross primes and elicits immunogenicity. Currently, we do not know the frequency at which alterations in structure and immunogenicity of transgenically expressed proteins occur or whether this is unique to transgenically expressed α AI. These investigations, however, demonstrate that transgenic expression of non-native proteins in plants may lead to the synthesis of structural variants with altered immunogenicity.

ABBREVIATIONS USED

α AI, α -amylase inhibitor-1; pea (*Pisum sativum* L.), transgenic pea; *Phaseolus vulgaris* L. cv. Tendergreen, *Pisum sativum* L. expressing α -amylase inhibitor-1 from the common bean; MALDI-TOF-MS, matrix-assisted laser desorption/ionization-time-of-flight-mass spectrometry.

ACKNOWLEDGMENT

We thank Aulikki Koskinen and Anne Prins for excellent technical assistance and David Tremethick, Ian Young, and Klaus Matthaei for their helpful discussions and preparation of the manuscript. GenBank accession number for common bean cv. Pinto is AY603476.

Supporting Information Available: Amino acid sequence of α AI from common bean and consumption of pea seed meal predisposed to Th₂-type inflammation. This material is available free of charge via the Internet at <http://pubs.acs.org>.
