The article demonstrates a method of simultaneous determination for 352 pesticide residues in grapes using primary–secondary amine (PSA) matrix solid phase dispersion (MSPD) cleanup and gas chromatography–mass spectrometry-selected ion monitoring (GC-MS-SIM). Grape samples (15 g) were mixed with 6 g of anhydrous magnesium sulfate and 1.5 g of sodium chloride, and then extracted with acetonitrile (15 mL) and cleaned up with 0.3 g of dispersive PSA. The analytes were determined by GC-MS-SIM. Four injections for one sample were acquired to cover a total of 352 pesticides. The limit of detection (LOD) for the method was 0.0017–0.2667 mg kg⁻¹, depending on the nature of compounds. The linear correlation coefficient (*r*) was equal to or greater than 0.95; at low, medium, and high fortification levels, recoveries ranged from 45% to 136% for 352 pesticides, among which the recoveries between 60%–120% accounted for 97%. The pesticides for which the relative standard deviations (RSD) were equal to or below 20% accounted for 95%. A positive of nine varieties of grape samples was detected out, one of which was obtained Changli city, Hebei province, China. Pesticides were identified by the retention time, molecule ions, fragment ions, and the abundance ratio of the selected ions. The analytical method was rugged, quick, cheap and effective, and suitable for the determination of a wide scope of 346 pesticides in grapes.

KEYWORDS: Grape; pesticide residues; PSA-MSPD; GC-MS-SIM

INTRODUCTION

It is well known that pesticides make important contributions to boost modern agricultural production but that they bring potential hazards to both the environment and food safety. Many international organizations and countries are greatly concerned about pesticide residues. To protect public health and ensure food safety, pesticide maximum residue limit (MRL) detection is established and has become an international threshold of entrance in international trade. As the consumption of grapes increase, the problem of pesticide residues in grape cause great concern. Up to now, CAC prescribes the MRL in grapes for 70 pesticides (1), USA is 102 (2), EU is 436 (3), Japan is 345 (4), and China is 5 (5). Presently, with the progress of scientific technique and the public's concern on food safety, more pesticides of MRL in grapes have been prescribed, and pesticide residual level is getting stricter. Naturally, there is much research on analytical techniques of residue pesticides, especially simultaneous determination of multiresidues. It has already become a hot topic. Many studies, which can simultaneously determine over a hundred pesticide residues, have been constantly published about agricultural produce such as fruits and vegetable (6), grains and

cereals (7), animal tissues (8), aquatic products (9, 10), edible fungi (11, 12), Chinese medicinal herbs (13), teas (14), etc. The author has retrieved 12 methods about the simultaneous determination of pesticide multiresidues in grapes since 2000. The varieties of pesticide that have been determined are 11 (15), 12 (16), 13 (17), 15 (18), 17 (19), 27 (20), 38 (21), 50 (22, 23), 67 (24), 74 (25), and 171 (26). Some methods are exclusively devoted to detect residue pesticides in grapes, and others can be applied to different fruits and vegetables, including grapes. Gonzalez et al. proposed a multiresidue method of determination of 11 new fungicides in grapes. Samples were extracted with ethyl acetate/hexane (1:1, v/v) and cleaned up with graphitized carbon blacks (GCB)/PSA solid phase extraction (SPE) cartridges using acetonitrile/toluene (3:1, v/v) as eluent, and the target compound was determined by gas chromatography–ion trap mass spectroscopy (GC-ITMS). LOD < 0.01 mg kg⁻¹, RSD < 16% (15). Oliva et al. and Navarro et al. described a multiresidue method for determining 12 insecticides and 17 fungicides in grapes. The matrix once extracted with an acetone/dichloromethane (1:1, v/v) mixture was filtered and concentrated. Nitrogen phosphorus detector (NPD) and electron capture detector (ECD) were used to identify and quantify the target, the findings being confirmed using a mass spectroscopy detector (MSD); no cleanup was necessary for either NPD or ECD (16, 17). Fernández et al.

researched a multiresidue method for the determination of 13 carbamate residues in grapes by matrix solid phase dispersion–liquid chromatography mass spectrometry (MSPD-LC-MS). The efficiency of different solid phases (C18, C8 cyano, amine and phenyl) for the MSPD was compared. Mean recoveries using C 8 varied from 64–106% with a RSD of 5–15% in the concentration range of 0.01–10 mg kg⁻¹. The LOD ranged from 0.001 to 0.01 mg kg⁻¹ (18). Albero et al. developed a rapid multiresidue method for the determination of 15 herbicides in grapes. Samples were extracted and cleaned up by MSPD with Florisil, determined by GC-MS-SIM. The LOD ranged from 0.1 to 1.6 μg kg⁻¹, and recoveries ranged from 80 to 115%; RSD ≤ 10% (19). Cunha et al. used acetonitrile as extracting solvent and Quick, Easy, Cheap, Effective, Rugged and Safe (QuEChERS) for cleanup to analyze 27 representative pesticides in grapes. Recoveries were acceptable at three different spiking levels (from 0.04 to 2.5 μg g⁻¹), and RSD was from 3 to 21%. Limit of quantitation (LOQ) was from 0.02 to 5 μg g⁻¹ (20). Taylor et al. extracted 38 pesticides from grapes with crude extracts and no sample clean up before analysis by LC-MS-MS. Mean recoveries ranged from 63% to 96% with RSD < 20% (21). Savant et al. determined 50 pesticides in grape by GC-ITMS-multiple reaction monitoring (MRM). The samples were extracted by ethyl acetate and cleaned up by dispersive solid phase extraction with PSA (25 mg). Sample preparation was done by using a programmable temperature vaporizer (PTV) with a large volume injection (20 μL) through a multibaffled linear vessel. Recoveries ranged within 70–120% at 10, 20, and 50 ng g⁻¹ with RSD < 20% (*n* = 6) (22). Albero et al. developed a multiresidue method for the simultaneous determination of 50 pesticides in commercial juices. The extraction procedure was carried out in C18 columns, eluted by hexane-ethyl acetate (1:1, v/v), and determined by GC-MS-SIM. Average recoveries were higher than 91% with a RSD lower than 9% in the concentration range of 0.02–0.1 μg mL⁻¹; LOD ranged from 0.1 to 4.6 μg L⁻¹ (23). Cesnik et al. described pesticide monitoring of 47 samples of wine grapes. Two internal analytical methods were used for the determination of pesticides by GC-MS. Multiple residues were found in 41 samples (87.2%). The highest number of pesticides detected was seven. Folpet (97.9%), cyprodinil (51.1%), dithiocarbamates (44.7%), chlorothalonil (23.4%), chlorpyriphos (19.1%), and Pyrimethanil (14.9%) were the most frequently found pesticides in grapes (24). Didier et al. described a multiresidue method for the determination of 74 pesticides in grapes and extracted them with ethyl acetate, with no additional cleanup steps, and determined them by LC-ESI-MS-MS. The LOQ was 0.01 mg kg⁻¹. Recoveries, RSD, and accuracy values of the method fulfilled the criteria of validation commonly admitted (25). Hiemstra et al. developed a multiresidue method for the simultaneous target analysis of 171 pesticides and metabolites in grapes by LC-MS-MS. Pesticide residues were extracted/partitioned from the samples with acetone/dichloromethane/light petroleum. Recoveries ranged from 70% to 110%, with RSD < 15%. The LOQ was 0.01 mg kg⁻¹ (26).

According to the 2006 statistical data of Organisation Internationale de la Vigne et du Vin (OIV), the area of the globe producing grapes was 7.812 million hectares, and production was 667.7 millions of quintals. The world production of wine in 2006 was, without juices and musts, 282.8 millions of hectolitres. China ranked the seventh after France, Italy, Spain, USA, Australia, and Argentina (27). Pesticide residue monitoring and control no doubt is an undertaking of great magnitude. Changli city, Hebei province, P.R. China is mainly a dry red wine producing area in China, with the same latitude as that of Bordeaux France, and the soil and coastal moist climate is similar to that of Bordeaux France. Vineyard area measurements are several

hundred thousand acres, and the task of monitoring the pesticide residues was heavy. Meanwhile, grapes are a complicated matrix containing a great deal of sugar, pigment, and organic acid, etc. It is necessary to select an analytical technique with higher sensitivity and selectivity for enlarging the varieties of pesticides detected and enhancing analysis speed. Compared with the three-sample preparation and cleanup methods such as those of Lehotay et al. (28), Pang et al. (29), and Wong et al. (30), this work established a method of the 346 of pesticides multiresidue method by acetonitrile extraction and PSA MSPD cleanup and GC-MS-SIM detection. The method, which is efficient, fast, and of low cost, is applicable to routine screening, validation, and quantification of hundreds of pesticides in grapes.

MATERIALS AND METHODS

Materials and Reagents. Pesticide standards, all ≥95% Purity, were obtained from LGC Promochem (Wesel, Germany). Acetonitrile, hexane and toluene were of LC grade for residue analysis obtained from J. T. Baker (Phillipsburg, NJ). Magnesium sulfate (anhydrous) was purchased from Sigma Inc. (USA), heated to 550 °C for five hours, and kept in a desiccator. PSA (40 μm) was obtained from Varian Inc. (USA). Envi-18 cartridges (12 mL/2.0 g) and Envi-Carb cartridges (6 mL/0.5 g) were from Supelco Inc. (USA). Sep-Pak NH₂ cartridges (3 mL/0.5 g) and Oasis HLB cartridges (6 mL/500 mg) were purchased from Waters (USA). Deionized water purified by Milli-Q. Grapes were purchased from Vineyard in Changli, Hebei province, China.

Solutions. *Stock Standard Solutions.* Accurately weighed individual pesticide standards were dissolved in toluene, toluene-acetone, dichloromethane, and methanol, etc., and the concentration of pesticides were at the range of 500–1000 ng μL⁻¹, which were based on the solubility of each compound.

Mixture Standard Solution. Three hundred fifty-two pesticides were divided into four groups, A, B, C, D, and each group was diluted in toluene; the concentrations were between 2.5 and 240 ng μL⁻¹.

Internal Solution. Accurately weighed 3.5 mg of heptachlor-epoxide was placed in a 100 mL volumetric flask, dissolved, and diluted to volume with toluene.

Instrumentation. GC-MS. Model 6890 N gas chromatograph performed with an Agilent 5973N MSD equipped with EI. Capillary column DB-1701 (30 m × 0.25 mm × 0.25 μm). GC-MS conditions: column temperature was maintained at 40 °C for 1 min and then programmed to 130 at 30 °C min⁻¹, to 250 at 5 °C min⁻¹, then attached to 300 at 10 °C min⁻¹, and held for 5 min. Carrier gas at a rate of 1.2 mL min⁻¹ was helium, with a purity ≥99.999%. The injection port temperature was 290 °C; 1 μL was injected in splitless linear with the purge on after 1.5 min. The ionization energy was 70 eV, the ion source temperature 230 °C, and the GC-MS interface temperature 280 °C. The monitoring mode was set to selected ion monitoring.

Homogenizer. The homogenizer was T-25B (Janke & Kunkel, Staufen, Germany); centrifuge, Z320 (B. Hermle AG, Gosheim, Germany); rotary evaporator-Buchi, EL131 (Flawil, Switzerland); nitrogen evaporator, EVAP 112 (Organonation Associates, Inc., New Berlin, MA).

Extraction and Cleanup. *Method A.* A 15.0 g portion of homogenized grapes was accurately weighed to a 50 mL glassware centrifuge tube with stopper and mixed with 15 mL of acetonitrile. The capped tube was shaken for 1 min before 6.0 g of anhydrous magnesium sulfate and 1.5 g of sodium chloride were added into it, then the cap was screwed, the tube was vigorously shaken for about 10 s by hand, transferred to the oscillator for shaking for 5 min, and eventually put into the centrifuge for 5 min at 3000 rpm. The extracts (upper layer) were transferred to another 50 mL glassware centrifuge tube with stopper containing 0.3 g of PSA and 1.8 g of anhydrous magnesium sulfates. The tube was capped, shaken for 5 min, and centrifuged for 3 min at 3000 rpm; 7.5 mL of the supernatant was pipetted to a pear-shaped flask, concentrated to ca. 0.5 mL by rotary evaporation at 40 °C, exchanged with hexane (2 × 5 mL) twice, and diluted to ca. 1 mL. Forty microliters of internal standard solution was added. The solution, after thoroughly mixing and passing the 0.20 μm filter membrane, was ready for GC-MS analysis.

Method B. Grape samples (20 g) were extracted with 40 mL of acetonitrile, salted out with sodium chloride. The coextractive was concentrated, cleaned up with Envi-18, Envi-carb, and sep-pak NH₂ cartridges in series, and eluted with 25 mL of acetonitrile-toluene (3 + 1). The eluate was concentrated to ca. 1 mL, added to internal standard solution after solvent exchange, and then was ready for GC-MS analysis.

Method C. Grape samples (20 g) were extracted with 40 mL of acetonitrile, salted out with sodium chloride, the coextractive concentrated to ca. 1 mL, added to 20 mL of water, then the aqueous solution transferred to the Oasis HLB cartridge. While all the liquid passed through the cartridge, the cartridge was dried under vacuum. Then it was attached to NH₂ cartridges, the tandem cartridge was eluted with 5 mL each of 80:20, 50:50, and 20:80 ethyl acetate/hexane. The eluate was concentrated, dissolved, and then was ready for GC-MS analysis.

Qualitative and Quantitative Analysis. The qualitative pesticide was based on the retention time of the peaks and the abundance ratios of the selected ions. If the abundance ratios of the selected ions were within the expected limits (32), the sample was confirmed to contain the pesticide. If the results were not definitive, the sample was reinjected with one or two additional confirmatory ions of the suspicious pesticides. Quantification was performed by using an internal standard. To compensate for the matrix effect, quantitation was based on a mixed standard solution prepared in blank matrix extract. The LOD was set with concentration levels giving a signal-to-noise ratio ≥ 5 . LOQ was calculated to $2 \times$ LOD.

RESULTS AND DISCUSSION

Designing Test Procedures Based on Interval Grouping. All pesticides were conducted to proceed full scan, then base peaks, fragment ions, and retention times were selected. To enlarge the variety scope of the pesticides determined, on the basis of the concept of combining information acquisition and analytical technology, and designed monitoring program the groups were divided according to the time frame so that determination of multiresidues was as simple as single residue determination. On the basis of the retention times, the 352 compounds were divided into four groups: A, B, C, and D. One quantifying ion and two or three qualifying ions were selected for each compound. The analysis parameters optimized for the compounds are listed in **Table 1**. SIM program for the four groups A, B, C, D are listed in **Table 2**.

Comparison and Selection of Extraction and Cleanup Condition of Samples. Diverse extraction and cleanup procedures purposed to acquire the better recovery of analyte and less matrix interference (31). Three methods were conducted in this work, including Lehotay (labeled method A) (28), Pang (labeled method B) (29), and Wong (labeled method C) (30). In comparative experiments, fortification recovery experiments were conducted at low level, and then samples were extracted and cleaned up, respectively, with the three methods described above and analyzed by the monitoring mode described above. The data of recoveries and RSDs are listed in **Table 3**. The results of the statistic data are shown in **Table 4**.

From **Table 4**, comparing the three different methods, the number of pesticides that the average recoveries ranged from 60% to 120% were 340, 332, and 269, respectively, accounting for 96.6%, 92.9%, and 76.4% of all results. Among the results mentioned above, the recoveries were between 80% and 120%, and 288 analytes were determined by method A, 320 by method B, and 163 by method C.

Pesticides determined by method A whose recoveries were less than 40% contained resemthrin, cycloxydim, fenamiphos sulfone, and carboxim. Recoveries for all pesticides disposed by method B were higher than 60%. The elute solvents used in method C were nonpolar so as to influence the eluate of some polar pesticides including some organophosphorus, carbamate, and triazine herbicide, etc.. Recoveries were below 40%, for

instance, allidochlor, etridiazol, chlormephos, prophan, cycloate, diphenylamine, ethalfluralin, phorate, thiometon, quintozone, atrazine-desethyl, clomazone, diazinon, fonofos, etrimfos, simazine, propetamphos, and sebumeton. The number of pesticide recoveries which were over 120%, determined by method A is 3, by method B is 25, and by method C is 14. From the above, three methods for the determination of multiresidue pesticides were applied widely. From the comparative experiments, methods A and B were superior to method C.

From the experiments, the number of RSDs lower than 10% was 287, 292, 262 pesticides by method A, B, and C, respectively, among which 341, 340, and 334 analyte RSDs were lower than 20%, accounting for 96.9%, 96.6%, and 94.9%, respectively. It showed that these methods have relatively good repeatability.

For the effect of removing pigment, the coextractive cleaned up by method B was colorless no matter what the matrix color was. However, for the dark color matrix, the samples were light yellow, which was cleaned up by methods A and C. Therefore, on the effect of removing pigment, method B was better than A and C, but if considering the time of sample preparation and consumption of solvents, method A was rapid and was of low cost. The advantage was especially suitable for the determination of multiple samples. Thus, the following validation experiment for the selected method A was conducted. However, after about 300 of injections for samples disposed by method A, the inner tube must be cleaned or changed. Otherwise, recoveries for some pesticides will fall, e.g., pyrethroids.

Linear Range and LOD for the Proposed Method. The linear correlation coefficients for 352 pesticides were greater than 0.95, among which 318 pesticide linear correlation coefficients greater than 0.99 account for 90.3%, 34 pesticides below 0.99, accounting for 9.7%. It can be seen that the method has relatively higher sensitivity and a good linear range. LOD for 352 pesticides was between 0.0017 to 0.2661 mg kg⁻¹, among which the LOD was below 0.01 mg kg⁻¹ accounting for 40%; between 0.01 to 0.05 mg kg⁻¹ accounting for 56%; over 0.05 mg kg⁻¹, accounting for 4%. The LOD of the method, the linear range, and the linear correlation coefficient for 352 pesticides are shown in **Table 1**.

Evaluation of the Method Efficiency. The method efficiency was evaluated by recovery tests at low, medium, and high fortification levels using 8 different grapes (including wine grapes, wild wine grapes, and table grapes, etc.), while matrix standards were substituted for solution standards to quantify targeting pesticides correct for the matrix effect. See **Table 5** for test results. It could be seen from **Table 5** that the 352 compounds with their recoveries between 60% and 120% at low, medium, and high fortification levels were, respectively, 341, 341, and 346, accounting for 97%, 97%, and 98.2% of all results. The compounds with recoveries less than 40% at three fortification levels were resemthrin (2 isomers), cycloxydim, fenamiphos sulfone, and carboxim; the compounds with recoveries higher than 120% were bromfeninfos, chlorgenson, aziprotryne, hexaflumuron, and chlorfluazuron. The compounds with RSDs less than 20% at three fortification levels were 333, 322, and 327, respectively, which accounted for 94.6%, 91.5%, and 92.9%. The compounds with RSDs higher than 30% were only 7, 6, and 7 varieties, accounting for less than 2%. In general, some pesticides that were not detected by the method because their recoveries were less than 40%, and RSD was over 20%. Besides, the RSD of fenamiphos sulfone was relatively high, and its recoveries were unstable, which were not applicable to the detection of this method. In conclusion, the method is applicable to a quantified determination of 346 compounds.

The above test results further proved that the method has broad applicability for the determination of pesticide

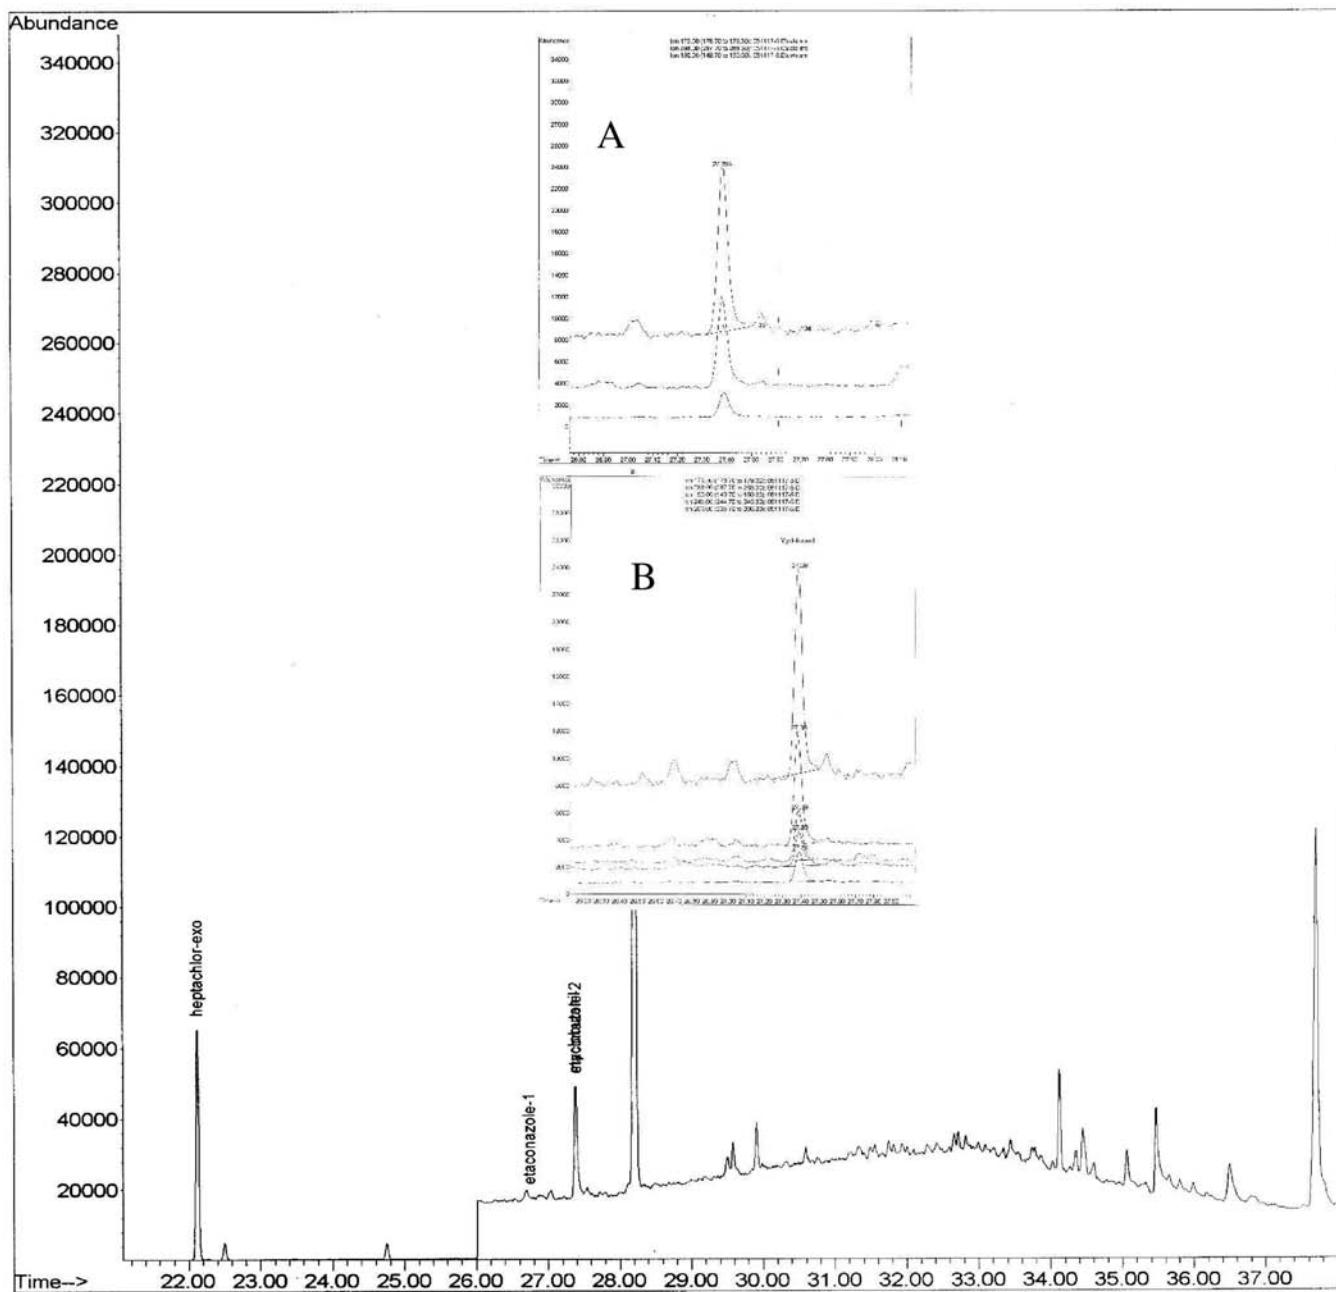

Figure 1. Total ion chromatogram of a blank grape sample cleaned up by dispersive SPE. (Inset) Extracted ion chromatogram for myclobutanol at 27.38 min; extracted ion for (A) myclobutanol, m/z 179.0, 288.0, and 150.0; (B) m/z 179.0, 288.0, 150.0, 245.0, and 206.0.

multiresidues in grapes. The stable and reliable repeatability of this method makes it an effective routine analytical method in international trade and in residue monitoring by countries all over the world.

Determination in Real Samples. According to the detecting program described above, 352 pesticides and related chemicals from nine varieties of grapes, such as Dragoneye, Caberner, Muscathambury, Cabemetsauvignon, V. amurensis, Sirah, Merlot, Gamay, and Murasaki, were determined. A peak of an unknown compound was found at 27.38 min in Dragoneye. It was preliminarily identified as myclobutanol, which is shown in **Figure 1A**, by comparing the retention time, three fragment ions 179.0, 288.0, and 150.0, and the abundance ratio of selected ions of the unknown peak with that of the standard compounds peak. To further verify the unknown compound, additional two fragment ions, 245.0 and 206.0, were monitored, as shown in **Figure 1B**.

The result showed that fragment ions of the target analyte were the same as those of the standard compound, and the relative abundance ratio of selected ions was in the range of the maximum tolerant deviation. The unknown compound was ascertained as myclobutanol, the concentration of which was 0.029 mg kg^{-1} , and then upon communication with the grape planter, we knew that the pesticide was used to prevent and cure *Phoma citricarpa* and that it can be detected due to the mistaken utility.

Conclusions. Qualitative and quantitative analyses and determination for grape samples were performed, and the results showed that the method has a higher sensitivity and good selectivity and that 352 pesticides and related chemical residues were determined at a time suitable for monitoring and screening for multiresidue pesticides of grape samples.

ABBREVIATIONS USED

PSA, primary secondary amine; MSPD, matrix solid phase dispersion; LOD, limit of detection; RSD, relative standard deviation; MRL, maximum residue limit; GCB, graphitized carbon blacks; SPE, solid phase extraction; GC-ITMS, gas chromatography-ion trap mass spectroscopy; NPD, nitrogen phosphorus detector; ECD, electron capture detector; MSD, mass spectroscopy detector; MSPD-LC-MS, matrix solid phase dispersion-liquid chromatography-mass spectrometer; QuEChERS, Quick, Easy, Cheap, Effective, Rugged and Safe; LOQ, limit of quantitation; MRM, multiple reaction monitoring; PTV, programmable temperature vaporizer; OIV, Organisation Internationale de la Vigne et du Vin.
