# $\mathrm{Al}_{69} \mathrm{Ta}_{39}-\mathrm{a}$ new variant of a face-centred cubic giant cell structure 

Stefan Mahne and Bernd Harbrecht*<br>Institut für Anorganische Chemie, Universität Bonn, Gerhard-Domagk-Str. 1, D-53121 Bonn (Germany)

(Received July 9, 1993)

#### Abstract

The structure of $\mathrm{Al}_{69} \mathrm{Ta}_{39}, \mathrm{cF} 432, a=1915.3(10) \mathrm{pm}, F \overline{4} 3 m, Z=4,38$ variables, was determined from 523 X -ray intensities of a single crystal with $I>3 \sigma(I)$ and refined to $w R(I)=0.050 . \mathrm{Al}_{69} \mathrm{Ta}_{39}$ represents a new structure type composed of four compositionally and three topologically distinct metal atom clusters as present in $\alpha$-Mn-, $\gamma$ -brass- and $\mathrm{Cd}_{45} \mathrm{Sm}_{11}$-type structures. The compositions of the clusters range from $\mathrm{Al}_{10} \mathrm{Ta}_{16}$ to $\mathrm{Al}_{23} \mathrm{Ta}$. Deviations from the crystallographic composition $\mathrm{Al}_{72} \mathrm{Ta}_{39}$ are due to $50 \%$ occupation of one Al site. Eleven out of 17 primary coordination polyhedra are of the Frank-Kasper type. The remaining polyhedra can also be considered as being exclusively terminated by triangulated faces. They are either of b.c.c. type or they combine features of both Frank-Kasper and b.c.c. coordinations.

## 1. Introduction

Although the phases of the Al-Ta system have been the subject of several investigations [1-9], only two phases in the neighbourhood of the elemental constituents have been characterized structurally so far, namely $\mathrm{Al}_{3} \mathrm{Ta}$ of $\mathrm{Al}_{3}$ Ti-type structure [1] and the Tarich phase $\mathrm{AlTa}_{2}$ adopting a $\sigma$ - CrFe -type structure [2]. The information about the lattice symmetries of further intermediate phases is conflicting [3, 4, 6]. Just recently we performed a combined X-ray and electron diffraction study which proved that the symmetry of the phase which has been termed $\mathrm{Al}_{17} \mathrm{Ta}_{12}$ [3], $\mathrm{Al}_{3} \mathrm{Ta}_{2}[4,6]$ or $\mathrm{Al}_{2} \mathrm{Ta}$ [8] is face-centred cubic [9].
In 1965 Raman already presumed that the large cubic cell of the phase which he named $\mathrm{Al}_{17} \mathrm{Ta}_{12}$ arises from an $\alpha$ - Mn - or $\gamma-\mathrm{Cu}_{5} \mathrm{Zn}_{8}$-type superstructure [3]. F.c.c. phases with comparable lattice constants of about 2 nm are e.g. $\mathrm{Cu}_{41} \mathrm{Sn}_{11}, \mathrm{cF} 416$, forming a $\gamma$-brass superstructure [10], $\mathrm{Mg}_{44} \mathrm{Rh}_{7}, \mathrm{cF} 408$ [11] and $\mathrm{Cd}_{45} \mathrm{Sm}_{11}, \mathrm{cF} 448$ [12]. The latter two materials contain atom clusters as present in $\alpha$-Mn and $\gamma$-brass related structures. Since we were not able to interpret the powder X-ray diffractogram of the cubic phase on the basis of available structural data of giant cell structures, we made efforts to grow crystals of that phase in order to determine the structure from single-crystal X-ray intensities. Here we report the results of the single-crystal structure

[^0]analysis of the phase, the composition of which turned out to be $\mathrm{Al}_{69} \mathrm{Ta}_{39}$.

## 2. Sample preparation and crystal growth

The title phase can be synthesized by arc melting of the elements ( $\mathrm{Al} 99.93 \%$, Ta $99.9 \%$; cold-pressed pellets of about 300 mg ). According to Guinier photographs, as-cast samples of compositions $0.35 \leqslant x_{\mathrm{Ta}} \leqslant 0.45$ always contained traces of $\mathrm{Al}_{3} \mathrm{Ta}$ and/ or $\sigma$-AlTa ${ }_{2}$. Although the samples showed good crystallinity, no single crystals could be found. Annealing experiments at 1720 K led to monoclinic AITa [9] by evaporation of aluminium [7]. Coarser material was obtained from ingots of $\mathrm{Al}_{3} \mathrm{Ta}$. The samples were wrapped in tantalum foil ( $99.9 \% \mathrm{Ta}$ ) and transferred into a Ta ampoule which was closed by welding. Subsequently reactions were performed in an induction furnace using a cyclic temperature programme, running 5 cycles of 3 min each in the temperature interval between 1720 and 1820 K . A Guinier photograph of the ingot showed that the cubic phase was formed. The Ta foil was mainly transformed into $\sigma-\mathrm{AlTa}_{2}$ by reaction with evaporated Al .

## 3. Single-crystal X-ray structure analysis

The quality of several crystals was checked with a precession camera. The photograph of a single crystal
of approximate size $50 \times 70 \times 80 \mu \mathrm{~m}^{3}$ mounted along a face diagonal confirmed the cubic F-type lattice and pointed to Laue symmetry $m \overline{3} m$. Possible space groups are $F 432$ (No. 209), $F \overline{4} 3 m$ (No. 216) and $F m \overline{3} m$ (No. 225) [13]. 5169 intensities were collected in a $2 \Theta$ range from $2^{\circ}$ to $46^{\circ}$ by a CAD4 automatic four-circle diffractometer in an $\omega-2 \Theta$ scan mode using $\mathrm{Ag} \mathrm{K} \alpha$ radiation ( $50 \mathrm{kV}, 26 \mathrm{~mA}$ ). The lattice parameter determined from 25 reflections is $a=1915.3(10) \mathrm{pm}$. The orientation matrix was controlled every 600 reflections. $\psi$ scans for four reflections were carried out for empirical absorption correction.

Data reduction and absorption correction with the $\psi$ scan data were performed with the program package SDP Plus [14]. Data averaging in space groups $\mathrm{Fm} 3 m$ (No. 225), Fm3 (No. 202) and $F \overline{4} 3 m$ (No. 216) led to internal $R_{\mathrm{i}}(I)$ of $0.064,0.063$ and 0.061 for 524,840 and 977 independent, observed and accepted reflections respectively. Therefore a structure of Laue symmetry $m \overline{3} m$ was assumed. For reasons given below, space group $F \overline{4} 3 m$ was finally chosen for the structure refinement. Including anomalous dispersion effects, 523 intensities ( $I>3 \sigma(I)$ ) were used to refine 38 variables.
Since we could not derive a structural model using Patterson or direct methods of the program shelx 76 [15], we attempted to develop a model on the basis of known structural data assuming that Ta atoms occupy only sites with coordination numbers $\mathrm{CN}>12$. Following Raman's idea from 1965 of an $\alpha-\mathrm{Mn}$ superstructure, the $\alpha$-Mn structure [16] was analysed in terms of coordination numbers. It can also be described using the cluster concept developed by Bradley and Jones [17]. The term "cluster" used here should not be mistaken for the idea of isolated metal atom clusters because of the close packing in intermetallics. Thereafter $\alpha-\mathrm{Mn}$ consists of one sort of cluster of point symmetry $\overline{4} 3 \mathrm{~m}$ built of nested units. It is composed of a central atom at a site labelled CC which has CN 16. Twelve atoms with CN 12 form a truncated tetrahedron (site TT) and four atoms with CN 16 which are located above the hexagonal faces of TT build an outer tetrahedron (site OT) about CC. Finally 12 additional atoms with CN 13 positioned at the vertices of a cubooctahedron (site CO) complete the cluster (see Fig. $3(\mathrm{a})$ ). This cluster of 29 atoms is located at 000 and $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ in a cI58 cell. The tendency of the distribution of Al and Ta atoms on sites of different CNs is known for $\sigma$ - $\mathrm{AlTa}_{2}$, with Al occupying sites of CN 12 and Ta with CN 14 and 15 positions [2]. If the sites in $\alpha-\mathrm{Mn}$ with CNs 13 and 16 were occupied by Ta and those with CN 12 by Al , the composition would be $\mathrm{Al}_{17} \mathrm{Ta}_{12}$. A corresponding decoration is realized in the structure of the $\chi$ phase $\mathrm{Al}_{12} \mathrm{Mg}_{17}$ [18].

In order to generate a structural model, the atom positions of $\alpha-\mathrm{Mn}$ were transformed according to the following group-subgroup relations: $\overline{\overline{4}} 3 \mathrm{~m}$ (cI58) $-k 2 \rightarrow P \overline{4} 3 m$ (cP58) $-k 2 ; 2 a, 2 a, 2 a \rightarrow F \overline{4} 3 m$ (cF464). Whereas in the body-centred cell the sequence of clusters along [111] is $A A$, it is $A B$ in the primitive cell and $A B C D$ in the face-centred cell. Thus four distinct clusters, termed $A, B, C$ and $D$ with centres at $000, \frac{1}{4} \frac{1}{4} \frac{1}{4} \frac{1}{2} \frac{1}{2} \frac{1}{2}$ and $\frac{3}{4} \frac{3}{4} \frac{3}{4}$ respectively, are generated (see Fig. 1). As a starting model the respective sites with CNs 16 and 13, i.e. CC, OT and CO for clusters $A$ to $D$, were occupied by Ta atoms. The program SDP Plus refined this model to $R(F)=0.14$. Strikingly, the displacement parameters of the Ta atoms at site CC in cluster $C$, site OT in cluster $D$ and sites CO in clusters $B$ and $D$ increased drastically. The atoms at these sites were removed. Difference Fourier synthesis using the program shelx 76 [15] yields the Al atoms of another nine sites, among them again CO of clusters $B$ and $D$ and OT of cluster $D$, but no noticeable electron density at CC of cluster $C$ was observed. During the refinement a non-Poisson weighting scheme $w^{\prime}=1 / \sigma(F)^{2}$ was used. After applying an additional weighting scheme $w=w^{\prime} \exp \left[r(\sin \Theta / \lambda)^{2}\right]$ with $r=0.2 \mathrm{~nm}^{2}$ [19], the structure refinements converged at $R(F)=0.039, w R(F)=0.025$ and $R(I)=0.059, w R(I)=0.050$. Table 1 contains the crystallographic data. Table 2 lists the final positional and isotropic displacement parameters of the 17 crystallographically different atoms. In cluster $D$ the displacement parameters of the two tetrahedra IT and OT forming a cube (Al6 and A17) were constrained; OH (Al8) is occupied only by $50 \% \mathrm{Al}$. Other types of disorder are observed for e.g. $\mathrm{Pt}_{3} \mathrm{Zn}_{10}$ [20] and ( $\mathrm{Fe}, \mathrm{Ni}$ ) $\mathrm{Zn}_{6.5}$ [21].

Fig. 1. Arrangement of cluster types $A, B, C$ and $D$ in the approximately 2 nm f.c.c. cell; the clusters are represented by cubo-octahedra.

| Weighting schemes | $w^{\prime}=1 / \sigma\left(F^{2}\right)$ |
|  | $w=w^{\prime} \exp \left[r\left(\mathrm{sin}^{\prime} \Theta / \lambda\right)^{2}\right]$ |
| $R(F), R\left(F^{2}\right)$ | with $r=0.2 \mathrm{~nm}$ |
| $R w(F) ; R w\left(F^{2}\right)$ | $0.039,0.059$ |
| Difference electron density $\Delta \rho$ | $10.3 \times 10^{-6} \mathrm{e} \mathrm{pm}$ |

Counting all sites, the number of atoms per unit cell is 444 ; the crystallographic composition is $\mathrm{Al}_{72} \mathrm{Ta}_{39}$. However, since site OH of cluster $D(\mathrm{Al} 8)$ is only half occupied, the Pearson symbol is cF432. Thus the chemical formula is $\mathrm{Al}_{69} \mathrm{Ta}_{39}$ if we neglect a phase width due to possible mutual Al-Ta substitution at some sites with $\mathrm{CN}<16$.

As seen from Table 3, there is a conspicuously short interatomic distance of 240 pm between All and Al 3
compared with the shortest $d(\mathrm{Al}-\mathrm{Al})$ of 264 pm in $\sigma$ $\mathrm{AlTa}_{2}$ and 286 pm in f.c.c. Al. Notice that comparable close contacts are also observed in the parent structure $\alpha-\mathrm{Mn}$ [16] and the derived carbide $\mathrm{Yb}_{10+x} \mathrm{Mn}_{13-x} \mathrm{C}_{18}$ [22]: Mn atoms at site TT are 226 or 223 pm apart respectively. This is about $17 \%$ shorter than the distance $\mathrm{Mn}-\mathrm{Mn}$ in f.c.c. manganese [23]. Alternative refinements in space group $F 23$ (No. 196) with uncoupled parameters for both All and Al3 (48h, $x x z$ in $F 43 m-t 2 \rightarrow 48 h, x y z$ in $F 23$ ) did not result in a significant change in that distance. Least-squares refinements in space group $F 23$ assuming merohedral twinning with twinning elements $m \|$ e.g. [110] (SHELXL92 [24]) did not alter the distance either.

## 4. Powder X-ray diffraction

A powder diffractogram of an arc-melted sample containing the cubic phase ( $a=1916.09(2) \mathrm{pm}$ ) and traces of $\mathrm{Al}_{3} \mathrm{Ta}$ was recorded stepwise in increments of $0.02^{\circ}$ in the $2 \Theta$ range $6^{\circ}-115^{\circ}$ with use of a PW 1050/25 (Philips, Eindhoven, Netherlands). The positional parameters of the derived structural model were used to start a Rietveld refinement [25]. The refinements converged at $R_{1}=0.043$ for $\mathrm{Al}_{69} \mathrm{Ta}_{39}$ and 0.078 for $\mathrm{Al}_{3} \mathrm{Ta}$. The agreement factors for the profile are $R_{\mathrm{P}}=0.079$ and $R_{P, w}=0.112$ with $w=1 / \sigma^{2}$. Shifts in the positional parameters gave rise to changes in the interatomic distances of less than 10 pm . Figure 2 shows the measured, calculated and difference diffractograms.

## 5. Structure description by a cluster concept

It is a proven method [17] to elucidate the architecture of such a complex structure in terms of $24-29$-atom clusters aligned along the threefold axes. As seen from Table 1, clusters $A$ and $B$ are of the point set combination CC, TT, OT, CO which is characteristic for $\alpha$-Mn-type clusters, whereas cluster $C$, built up by IT, $\mathrm{OT}, \mathrm{OH}$

(a)

(c)

Fig. 3. Idealized cluster types $A, B, C$ and $D$ in $\mathrm{Al}_{69} \mathrm{Ta}_{39}:($ a) $A$, $B, \alpha-\mathrm{Mn}$, sequence of sites $\mathrm{CC}, \mathrm{IT}, \mathrm{TT}, \mathrm{CO} ;(\mathrm{b}) \boldsymbol{C}, \gamma-\mathrm{Cu}_{5} \mathrm{Zn}_{8}$, sequence of sites IT, OT, OH, CO; (c) $D, \mathrm{Cd}_{45} \mathrm{Sm}_{11}(A)$, sequence of sites CC, IT, OT, OH, CO.
and CO sites, is of the $\gamma$-brass type. Cluster $D$ (CC, IT, OT, OH, CO) shows features of one sort of clusters found in $\mathrm{Cd}_{45} \mathrm{Sm}_{11}$, namely $A$ and $D$; Fornasini et al. [12] termed this cluster $\mathrm{Li}_{22} \mathrm{Si}_{5}$. Nesper and von Schnering, however, found that the centres (site CC) of all four clusters in the silicide are empty, resulting in the composition $\mathrm{Li}_{21} \mathrm{Si}_{5}$ [26]. Therefore we name the fully occupied cluster $D$ of $\mathrm{Al}_{69} \mathrm{Ta}_{39} \mathrm{Cd}_{45} \mathrm{Sm}_{11}(A)$. In contrast with e.g. $\mathrm{Li}_{21} \mathrm{Si}_{5}[26]$ or $\mathrm{Cu}_{41} \mathrm{Sn}_{11}[10]$ which are composed of clusters of a single type ( $\gamma$-brass) but with different atomic distributions, $\mathrm{Al}_{69} \mathrm{Ta}_{39}$ contains, like $\mathrm{Os}_{7} \mathrm{Sc}_{44}$ [27] or $\mathrm{Cd}_{45} \mathrm{Sm}_{11}$ [12], clusters of different types and compositions. The unique sequence of clusters along the threefold axis is (the local composition is given in parentheses): $A, \alpha-\mathrm{Mn}\left(\mathrm{Al}_{17} \mathrm{Ta}_{12}\right) ; B, \alpha-\mathrm{Mn}^{\prime}\left(\mathrm{Al}_{24} \mathrm{Ta}_{5}\right)$; $C, \gamma-\mathrm{Cu}_{5} \mathrm{Zn}_{8}\left(\mathrm{Al}_{10} \mathrm{Ta}_{16}\right) ; D, \mathrm{Cd}_{45} \mathrm{Sm}_{11}(A)\left(\mathrm{Al}_{23} \mathrm{Ta}\right)$ (see Fig. 3). Therefore $\mathrm{Al}_{69} \mathrm{Ta}_{39}$ represents a new structure type in the row of approximately 2 nm f.c.c. giant cell structures.

## 6. Structure description by an extended Frank-Kasper concept

A more detailed description of the structure is based on the coordination polyhedra of the 17 crystallograph-
ically distinct atoms. A fruitful concept to rationalize coordination configurations in several structurally complex intermetallic phases was developed by Frank and Kasper [28]. An important aspect of the concept is that a close packing of atoms represented by hard spheres of similar size is achieved in so-called tetrahedrally close-packed (t.c.p.) structures. Here all atoms are arranged to slightly distorted tetrahedra which fill space completely. As a consequence of such a packing, atoms of the first coordination shell of each atom form polyhedra which are exclusively terminated by triangulated faces. The analysis of possible coordination polyhedra was limited to configurations with coordinating atoms $\mathrm{S}_{q}$ having surface coordination numbers $q=5$ and 6 . Applying Euler's theorem to such triangulated convex polyhedra leads to two restrictions concerning the number $v_{q}$ of $\mathrm{S}_{q}$ atoms of the first coordination shell of coordination number $Z$ :
$v_{5}=12, \quad Z-v_{6}=12$
The four well-known Frank-Kasper (FK) polyhedra ( $Z=12,14,15,16$ ) follow from these relations. Frank and Kasper did not rule out the possibility of $\mathrm{S}_{4}$ atoms in t.c.p. structures, but they did not include this surface coordination in their analysis. Taking $\mathrm{S}_{4}$ atoms additionally into account leads to the relations
$2 v_{4}+v_{5}=12, \quad 2 Z-v_{5}-2 v_{6}=12$
Equations (2) contain the relations of the more constrained case $v_{4}=0$. Interestingly, from this point of view the CN 14 polyhedron taken from the b.c.c. structure can be considered as t.c.p.: $v_{4}=6, v_{5}=0$, $v_{6}=8, Z=14$. Subsequently we shall show that relation (2) holds for all coordination configurations occurring in $\mathrm{Al}_{69} \mathrm{Ta}_{39}$ as long as defects at the Al8 position are disregarded.
The coordination polyhedra about the 17 distinct atoms are depicted in Figs. 4-7. Fragments of distorted cubes which are reminiscent of a b.c.c. coordination are emphasized by bold lines. Characteristic data of the coordination polyhedra are listed in Table 4. The frequencies of the various surface atoms $S_{q}$ fulfil the relations of t.c.p. structures composed of $\mathrm{S}_{4}, \mathrm{~S}_{5}$ and $\mathrm{S}_{6}$ atoms. Eleven polyhedra are of the FK type, among them Ta1, Ta4 and Ta5 ( $Z=16$ ), Ta6 and $\mathrm{Ta} 7(Z=15)$, $\mathrm{Ta} 2(Z=14)$ and Al1-A15 $(Z=12)$. The configurations of Ta8 and Al6 are of b.c.c. type with $Z=14$; the remaining four (Ta3 and A17-A19) exhibit hybrids of b.c.c. and FK polyhedra.

The topological distinction of regions of FK-typecoordinated atoms and of atoms showing b.c.c-typeaffected coordination polyhedra is reflected in the unusually high Al content of cluster $D$. Ta8 at the centre of cluster $D$, which is exclusively surrounded by Al atoms, is the core of b.c.c.-related coordinations. The

TABLE 4. Coordination numbers, frequency of surface coordination numbers and mean distances central atom-coordination shell (pm) for $\mathrm{Al}_{69} \mathrm{Ta}_{39}$

| Cluster | Atom | $Z(=\mathrm{CN})$ | $v_{4}$ | $v_{5}$ | $v_{6}$ | $\langle d\rangle$ <br> $(\mathrm{pm})$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $A$ |  |  |  |  |  | 0 |
|  | Ta1 | 16 | 12 | 4 | 297 |  |
|  | Al1 | 12 | 0 | 12 | 0 | 279 |
|  | Ta2 | 14 | 0 | 12 | 2 | 293 |
|  | Ta3 | 15 | 1 | 10 | 4 | 299 |
|  | Ta4 | 16 | 0 | 12 | 4 | 309 |
|  | Al2 | 12 | 0 | 12 | 0 | 281 |
|  | Ta5 | 16 | 0 | 12 | 4 | 299 |
|  | Al3 | 12 | 0 | 12 | 0 | 279 |
|  | Al4 | 12 | 0 | 12 | 0 | 284 |
|  | Ta6 | 15 | 0 | 12 | 3 | 292 |
|  | Al5 | 12 | 0 | 12 | 0 | 282 |
|  | Ta7 | 15 | 0 | 12 | 3 | 300 |
|  | Ta8 | $14(11)$ | 6 | 0 | 8 | 272 |
|  | Al6 | 14 | 6 | 0 | 8 | 293 |
|  | Al7 | 13 | 3 | 6 | 4 | 284 |
|  | Al8 | 13 | 5 | 2 | 6 | 290 |
|  | Al9 | 14 | 4 | 4 | 6 | 296 |

mean distances between central and peripheral atoms show the expected dependence on the number of nearest neighbours. The value for Ta8 ( 272 pm ) is too small but can be rationalized by the $50 \%$ occupancy of the site of Al 8 , leading to a reduction in the coordination number from 14 to 11 .

It is interesting to notice the mutual influence of neighbouring clusters on the local coordination. Whereas the distinct sites (CC, TT, OT, CO) of the $\alpha$-Mn clusters originally have CNs $16,12,16,13$, these are changed to $16,12,14,15$ and $16,12,16,12$ for clusters $A$ and $B$ in $\mathrm{Al}_{69} \mathrm{Ta}_{39}$ respectively. The sites IT, $\mathrm{OT}, \mathrm{OH}$ and CO of $\gamma$-brass of original CNs 12,12 , 13,13 are altered to $12,15,12,15$ for cluster $C$ in $\mathrm{Al}_{69} \mathrm{Ta}_{39}$. The interaction between the clusters is "constructive" in the sense that all atoms of clusters $B$ and $C$ reach FK coordinations. This is not completely true for all atoms of cluster $A$, since Ta3 has one $S_{4}$ atom (Al6) in its coordination. Al6 provides the link to cluster $D$, which is built up of atoms which all have several $\mathrm{S}_{4}$ atoms in their coordination shells.

## 7. Conclusions

According to an X-ray crystal structure analysis, the composition of the cubic phase in the Al-Ta system hitherto called $\mathrm{Al}_{2} \mathrm{Ta}, \mathrm{Al}_{17} \mathrm{Ta}_{12}$ or $\mathrm{Al}_{3} \mathrm{Ta}_{2}$ is $\mathrm{Al}_{69} \mathrm{Ta}_{39}$, Pearson symbol cF432. Small deviations from this composition due to marginal mutual substitution at some sites with coordination numbers less than 16 seem possible.
$\mathrm{Al}_{69} \mathrm{Ta}_{39}$ represents a new type of approximately 2 nm f.c.c. giant cell structure. It is composed of three topologically distinct clusters similar to those in $\alpha-\mathrm{Mn}$, $\gamma-\mathrm{Cu}_{5} \mathrm{Zn}_{8}$ and $\mathrm{Cd}_{45} \mathrm{Sm}_{11}$.
The structure of $\mathrm{Al}_{69} \mathrm{Ta}_{39}$ can be regarded as a modified Frank-Kasper phase which is disturbed by partly disordered regions of high Al content. In these regions some coordinating atoms have surface coordination number four. Since all atoms have triangulated coordination shells, the local requirement for a description of the structure in terms of completely spacefilling tetrahedra is fulfilled.

## Acknowledgments

We like to thank Dr. G. Kreiner (Fachbereich Chemie, Universität Dortmund) for the intensity measurement and Dr. B. Brühne for her help with the drawings. This study was supported by the Deutsche Forschungsgemeinschaft, the Ministerium für Wissenschaft und Forschung, Nordrhein-Westfalen and by the Fonds der Chemischen Industrie.
