SYNOPSIS

The purpose of this study is to reinforce the flexible nylon-6 by using Poly (*p*-diphenyl methyl terephthalamide) (PMA) using MDI as a chain extender. Observation by scanning electron microscopy showed that the multiblock copolymer had a homogeneous texture. From the differential scanning calorimetry measurements, the multiblock copolymers were shown to have only one melting point, T_m , which is higher than that of nylon-6. The wide-angle X-ray diffraction pattern shows that nylon-6 has two diffraction peaks at $2\theta = 20^\circ$ and 23.8° . However, the multiblock copolymer has only one peak at $2\theta = 20^\circ$, indicating a different crystal structure of multiblock copolymers. The copolymers appears to have a significant reinforcing effect on the mechanical properties. © 1994 John Wiley & Sons, Inc.

INTRODUCTION

Recently, a number of attempts have been made to improve the mechanical properties of the aliphatic nylons by using physical blending and chemical modification with aromatic polyamides such as Kevlar, polybenzamide (PBA),¹⁻⁵ and poly (4,4'-diphenylsulfone terephthalamide) (PSA).⁷⁻⁹ As shown in our previous paper,^{6,7} the aliphatic nylon-6 was modified by the semirigid PSA, exhibiting better thermal and mechanical properties. In our studies, we used semirigid polyamide poly(*p*-diphenyl methyl terephthalamide) (PMA) with (4,4'-diphenylene methane diisocyanate) (MDI) as a chain extender to reinforce the aliphatic nylon-6. The chemical structure of PMA is shown below.

The semirigid PMA has the same monoclinic crystal structure¹⁰⁻¹³ as that of nylon-6.

EXPERIMENTAL

Materials

Nylon-6 is made by Formosa Chemical and Fiber Corporation. Nylon-6 was first dissolved in formic acid and then poured into an excess amount of water. Samples are refluxed with methanol and hot water for 16 h then dried under vacuum at 100°C for 8 h. The inherent viscosity ($\eta_{inh} = 1.24$) and \overline{M}_n (21,500) of nylon-6 are obtained from the literature.¹⁴

ϵ -Caprolactam, 6-aminohexanoic acid, hexamethylene diamine, 4,4'-diphenylene methane diisocyanate (MDI), 4,4'-diaminodiphenyl methane (DDM), and terephthaloyl dichloride (TPC) were the products from Merck Co., and used as received.

N-Methyl-2-pyrrolidone (NMP) was first distilled over CaH_2 at $92^\circ\text{--}94^\circ\text{C}/14$ mmHg and then stored in the molecular sieves. The moisture content of a 5% LiCl solution in NMP was 0.018 wt %, determined with a Karl-Fischer Moisture Meter, MKA-3, and Kyoto Electronic. Lithium chloride (LiCl) was dried under vacuum at 160°C for 5 h.

ing vibration), $1,650\text{ cm}^{-1}$ ($=\text{C}-\text{O}$), $1,560\text{ cm}^{-1}$ ($=\text{N}-\text{H}$ deformation), and $2,900$ and $2,770\text{ cm}^{-1}$ ($=\text{CH}_2$ stretching vibration) absorptions; while the characteristic IR spectra of PMA (curve Pm) are shown at $1,530\text{ cm}^{-1}$ ($=\text{C}_6\text{H}_4-\text{CH}_2-\text{C}_6\text{H}_4-$), $1,660\text{ cm}^{-1}$ ($=\text{CONH}-$) and $1,100\text{ cm}^{-1}$, 800 cm^{-1} ($=\text{C}_6\text{H}_4-$ on parasubstituted) adsorptions. The nylon-6-PMA block copolymers (curve BM₁ to BM₃) show the characteristic absorptions of both nylon-6 and PMA. Noticeable are characteristic absorptions of the aliphatic $-\text{CH}_2-$ at $2,900\text{ cm}^{-1}$, $2,770\text{ cm}^{-1}$, and at $1,530\text{ cm}^{-1}$ ($=\text{C}_6\text{H}_4-\text{CH}_2-\text{C}_6\text{H}_4$). In addition, nylon-6-PMA also shown are absorptions of $-\text{NHCONH}-$ at $1,620-1,640\text{ cm}^{-1}$, emanating from the reaction of the $-\text{NH}_2-$ on the prepolymer with the $-\text{NCO}$ group of the chain extender.

Thermal Properties of Block Copolymers

Polymers with aromatic ring structure could contribute to their thermal stability. In this study, the

presence of aromatic PMA in nylon-6 could be expected to provide better thermal properties. The thermal behavior of homopolymers and block copolymers measured by DSC is shown in Figure 2 and Table II. The results show that the glass transition temperature, T_g, and the melting point, T_m, of the block copolymers have increased compared with that of nylon-6. Because the transition temperature could indicate the behavior of molecular motion within the polymer, it could be used as a clue to identify the phase separation, or the compatibility. The glass transition temperature, T_g, of block copolymers shows only one peak, therefore, a compatible state of semi-rigid PMA with nylon-6 is pos-

Table II T_g and T_m Measured by D. S. C Analysis

sible in the block copolymers. From the analysis of DSC results, the melting temperature of the block copolymers is expected to rise with increasing PMA

content. This is the result of the strong hydrogen-bonding connecting the nylon molecule and the nearby urea group, and the immobilization of immobile structure of MDI. Therefore, the block copolymers exhibit a more regular and wholly crystal structure.

Wide-Angle X-Ray Diffraction

From the WAXS diffraction patterns in Figures 3 and 4, we know that nylon-6 has two diffraction peaks at $2\theta = 20^\circ$ and 23.8° . However, the block copolymer has only one peak at $2\theta = 20^\circ$. These results evidently indicate a new structure of the block copolymers is formed, that is, the $\alpha(200)$ plane of nylon-6-MDI-PMA block copolymer in a structure of nylon-6 forms a new crystal structure.

The data in Table III, though, indicate that the d-spacings of nylon-6 and block copolymers are similar, but the crystallite sizes differ from each other. The crystallite sizes of block copolymers is smaller than that of nylon-6.

Morphological Observation

Scanning electron microscopy (SEM) was used to observe the microstructure of block copolymers. The micrographs in Figure 5 show the uniform surface structure of the block copolymers, resulting from covalent molecular chain displaying homogeneous morphology in block copolymers.

Mechanical Properties of Copolymers

The mechanical properties of block copolymers are shown in Table IV and Figure 6. The tensile strength, T_b , and the initial modulus, M_i , of block copolymers are much better than those of nylon-6; 15% PMA content of the block copolymers is optimum, but the elongation of block copolymers is reduced. Obviously, nylon-6 is a ductile material originally, but after modification will become a stronger and more brittle material. The ordered block co-

polymers have better properties, not only because of the introduction of semirigid units, which caused a higher intramolecular stiffness, but also because of the increase in the intermolecular forces between

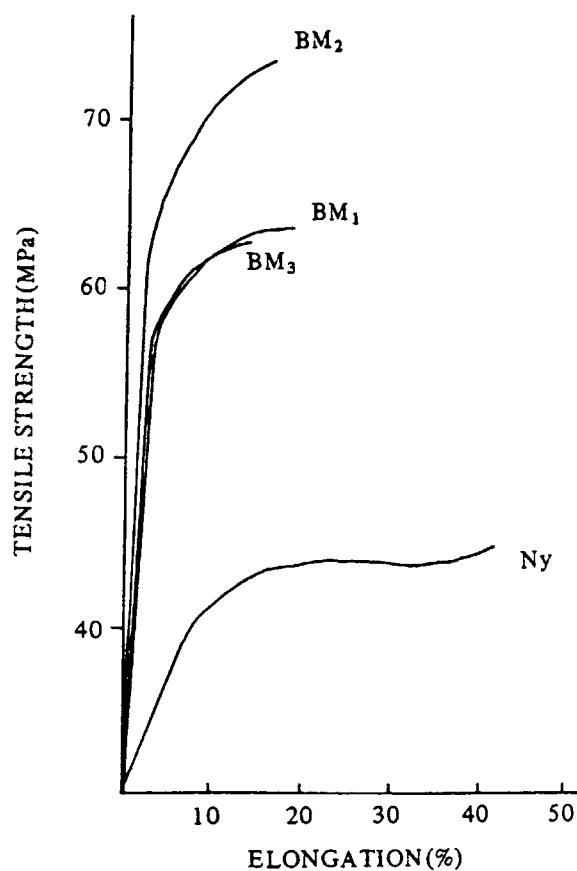

Figure 6 Stress-strain curves for multiblock copolymer: (Ny) nylon-6; (BM₁) PMA content of 10 wt %; (BM₂) PMA content of 15 wt %; (BM₃) PMA content of 20 wt %.

the polymer chains; thus forming a more uniform and compatible structure.

The loss tangent, $\tan \delta$, and tensile storage modulus, E' , of nylon-6 and block copolymers are presented in Figures 7 and 8, respectively. Figure 7 shows that the glass transition temperature, T_g , of block copolymers is higher than that of nylon-6 homopolymer, and rises as the content of PMA increases. This results from the resonance-planarity of the aromatic structure which will decrease the free rotation and flexibility of molecular chain. Although the greater the amount of PMA, the greater the aromatic structure of the molecular main chain, Table I shows that viscosity average molecular weight will decrease with the increasing PMA content. Because of these two factors, the glass temperature, T_g , of 20 wt % PMA will be slightly higher than that of 15 wt % PMA.

Figure 8, shows that mechanical performance is altered in the same way as the tensile test, and will be when 15 wt % PMA is add.

CONCLUSIONS

Three nylon-6-PMA block copolymers were synthesized by chemical extension using MDI as a chain extender. The reinforcement of nylon-6 with semirigid PMA proved to be successful. Block copolymers could exhibit better thermal and mechanical properties than those nylon-6.

According to the morphological features, the block copolymers exhibit a more homogeneous, compatible structure.

DSC analysis revealed that semirigid PMA reinforced nylon-6 forming copolymers exhibit both a higher glass transition and melting temperature than those of nylon-6 homopolymer; these will increase with the addition of PMA.

Analysis of wide-angle X-ray diffraction patterns shows that nylon-6 homopolymer has two diffraction peaks at $\theta = 20^\circ$ and 23.8° . However, the block copolymers have only one peak at $2\theta = 20^\circ$, indicating a different crystal structure of block copolymers.

From measurement of mechanical properties, the mechanical properties of block copolymer were found to be excellent compared with those of nylon-6 homopolymer, but 15 wt % PMA was the best. Therefore, the optimum PMA content in nylon-6 is suggested to be 15 wt %.
