ABSTRACT: Chlorohydrin water-swellable rubber—composed of chlorohydrin rubber (CHR), crosslinked polyacrylate (CPA), the amphiphilic compatibilizer poly(vinyl alcohol)-g-poly(butyl acrylate) (PVA-g-PBA), precipitated silica (PSA), and poly(ethylene glycol) (PEG)—was prepared. The dispersion of PEG in the blend was characterized by wide-angle X-ray diffraction (WAXD). The dependence of the water absorbing ratio by weight, the water-swelling ratio by volume, and the percentage loss by weight on PEG and PSA contents were investigated. The effects of PEG and PSA on the second water-swelling behaviors and long-term water-retention behaviors were also studied. Optimums for the water-absorbing and water-swelling abilities within the range of the experiment were obtained. © 2001 John Wiley & Sons, Inc. J Appl Polym Sci 79: 2509–2516, 2001

**Key words:** water-swellable rubber; chlorohydrin rubber; crosslinked polyacrylate; poly(ethylene glycol); precipitated silica

# **INTRODUCTION**

The development of water-swellable rubber (WSR) has been investigated in recent years as an area of considerable interest and importance.<sup>1-5</sup> As a kind of functional elastomer, WSR can both adapt itself to the deformation of structure, stopping water by means of elastic sealing and swell in water and by means of expanding volume. Because of convenient operation, reliable water-proofing, and wide application, WSR has opened vast vistas, especially in tunnel engineering, underground engineering, and civil engineering.

WSR is mainly made up of rubber and waterabsorbent resin. The rubber endows it with elasticity and ductility, while the water-absorbent resin supplies it with water absorptivity. The rubbers used are often nature rubber, butadiene rubber, isobutylene rubber, chloroprene rubber, acrylonitrile rubber, butyl rubber, or their copolymers. The water-absorbent resins are usually starch grafts, cellulose grafts, poly(ethylene oxide) polymers, poly(vinyl alcohol) polymers, etc.<sup>6</sup>

The pure gum stock of CHR has a very low strength. A strengthening agent has to be added to it in order to improve its strength and other physicomechanical properties. As a kind of strengthening agent of CHR, precipitated silica (PSA) can provide it with higher strength. Moreover, PSA has a lot of isolated hydroxyl groups on its surface<sup>7</sup> (Fig. 1), which can form hydrogen bonds with water easily and can make water be absorbed on the surface of PSA. Therefore, not only can PSA strengthen the pure gum stock of CHR, but it can also enhance the water absorptivity of WSR.

In WSR, rubber is the continuous phase, while water-absorbent resin is the dispersive phase.

Figure 1 Surface construct of precipitated silica.

Hydrophilic water-absorbent resin grains were isolated by hydrophobic rubber, and the waterabsorbing rate and water-swelling rate were very slow. The addition of a water-soluble polymer such as poly(ethylene glycol) to WSR can enhance its water-absorbing rate and improve its waterabsorbing properties.

Hydrophilic water-absorbent resin cannot generally disperse well in hydrophobic rubber, and it always breaks off from rubber networks easily. Decreasing the loss of water-absorbent resin is one of the most important goals in the research of WSR. The addition of a amphiphilic compatibilizer is an approach toward achieving that goal. In our previous research the amphiphilic compatibilizer PVA-g-PBA was synthesized and characterized<sup>8</sup> by using poly(vinyl alcohol) as a hydrophilic backbone and poly(butyl acrylate) as hydrophobic branched chains. The chlorohydrin waterswellable rubber, which is composed of CHR, CPA, PVA-g-PBA, PSA, and PEG, was prepared. The effects of PVA-g-PBA and crosslinked polyacrylate on water-swelling behaviors were also studied.<sup>9</sup> The morphological structure of the fractured surface of WSR was characterized by SEM. In this article the effects of PEG and PSA on water-swelling behaviors will be studied. The dispersion of PEG in WSR was characterized using WAXD.

## **EXPERIMENTAL**

#### **Materials**

The properties, purification levels and producers of chlorohydrin rubber, crosslinked polyacrylate salt, poly(ethylene glycol) (PEG), and PSA are the same as those in our previous article.<sup>9</sup> PVA-*g*-PBA with percentage grafting of 151.68% was prepared by us.<sup>8</sup>

#### Blending

As described in the previous article,<sup>9</sup> chlorohydrin rubber was masticated on an open mill for 2 min, and then a small amount of zinc stearate, compatibilizer PVA-g-PBA, water-absorbent resin CPA, PEG-2000, lead tetraoxide, PSA, surplus zinc stearate, and NA-22 was added in proper order, mixing continuously until apparent homogeneity. The compounded rubber stock was laid up and then remilled and passed through the open mill. A mixed compound with better dispersion was obtained.

# Vulcanizating

The mixed compound was preheated for 5 min and cured for 45 min at  $151 \pm 1^{\circ}$ C as described in the previous article.<sup>9</sup>

### Wide-Angle X-ray Diffraction

WAXD patterns were collected on a Rigaku D/Max- $\gamma$ A diffractometer at room temperature, using a nickel-filtered CuK $\alpha$  radiation generated at 50 KV and 150 mA in the  $2\theta$  range of  $5 \sim 60^{\circ}$ C.

#### First Water-Absorbing and Water-Swelling Abilities

The first water-absorbing and water-swelling abilities were estimated by the method described in the previous article.<sup>9</sup> The first water-absorbing ratio by weight,  $S_{w1}$ , the first water-swelling ratio by volume,  $S_{v1}$ , and the first percentage loss by weight,  $L_{w1}$ , were calculated using the following expression:

$$S_{w1} = W_2/W_1 - 1$$
  
 $S_{v1} = V_2/V_1 - 1$   
 $L_{w1} = 1 - W_3/W_1$ 

where  $W_1$  and  $W_2$  were the weights of a sample before and after the first water absorbing;  $V_1$  and  $V_2$ , the volumes of a sample before and after the first water swelling;  $W_3$ , the dried weight of a sample after the first water absorbing.

The first maximum water-absorbing ratio by weight,  $S_{w1m}$ , and the first maximum waterswelling ratio by volume,  $S_{v1m}$  were maximum values of  $S_{w1}$  and  $S_{v1}$ , respectively.

The first water-absorbing rate by weight,  $R_{w1}$ , was indicated by the slope of  $S_{w1}$  versus soak time, the first water-swelling rate by volume,  $R_{v1}$ , by the slope of  $S_{v1}$  versus soak time.

# The Second Water-Absorbing and Water-Swelling Abilities

The second water-absorbing and water-swelling abilities were estimated by the method described in the previous article.<sup>9</sup> The second water-absorbing ratio by weight,  $S_{w2}$ , and the second water-swelling ratio by volume,  $S_{v2}$ , were calculated using the following expression:

$${S}_{w2} = W_4/W_3 - 1$$
  
 ${S}_{v2} = V_4/V_3 - 1$ 

where  $W_3$  and  $W_4$  were the weights of a sample before and after the second water absorbing;  $V_3$ and  $V_4$ , the volumes of a sample before and after the second water swelling.

The second maximum water-absorbing ratio by weight,  $S_{w2m}$ , and the second maximum waterswelling ratio by volume,  $S_{v2m}$ , were maximum values of  $S_{w2}$  and  $S_{v2}$ , respectively.

The second water-absorbing rate by weight,  $R_{w2}$ , was indicated by the slope of  $S_{w2}$  versus soak time, the second water-swelling rate by volume,  $R_{v2}$ , by the slope of  $S_{v2}$  versus soak time.

#### **Long-Term Water-Retention Abilities**

A sample with the dimensions  $40 \times 20 \times 1 \text{ mm}^3$  was weighed and soaked in distilled water at

**Figure 2** WAXD patterns of (a) PEG; (b) CHR + PEG + CPA, CHR: 100 phr, PEG: 40 phr, CPA: 70 phr; (c) CHR; (d) CHR + PEG, CHR: 100 phr, PEG: 40 phr.

**Figure 3** Relationship of  $S_{w1}$  to soak time with various PEG-2000 contents; PVA-g-PBA: 10 phr; CPA: 70 phr; PSA: 40 phr.

room temperature. Then it was taken out, moisture on the surface was eliminated, and its weight and volume were measured every specified time until they did not change for several days.

## **RESULTS AND DISCUSSION**

#### Effect of PEG

#### Characterization of Dispersion of PEG by WAXD

The samples with PEG [Fig. 2(a)], CHR [Fig. 2(c)], CHR + PEG [Fig. 2(b)], and CHR + PEG + CPA[Fig. 2(d)] were investigated by means of WAXD in order to analyze the dispersion of PEG in WSR. As seen in Figure 2, the WAXD pattern of PEG shows characteristic diffraction peaks at 19.19, 23.35, and 26.53°C, while the WAXD pattern of CHR has no characteristic diffraction peaks. After PEG was blended with CHR, the characteristic diffraction peaks of PEG disappeared. Similarly, the characteristic diffraction peaks of PEG in PEG, CHR, and CPA ternary blend could not be seen. This shows that in a binary blend of PEG and CHR or a ternary blend of PEG, CHR, and CPA, PEG had a homogeneous dispersion and could not agglomerate by itself to form a crystalline region. The homogeneous dispersion of PEG in WSR played an important role in its increasing water-absorbing, water-swelling abilities.

#### Effect of PEG on the First Water-Swelling Abilities

 $R_{w1}$ ,  $R_{v1}$ , and  $S_{w1m}$ ,  $S_{v1m}$ . With an increase in PEG content,  $R_{w1}$  and  $R_{v1}$  dramatically speeded up (Figs. 3 and 4). This may be explained as follows: when WSR with no PEG was soaked in

**Figure 4** Relationship of  $S_{v1}$  to soak time with various PEG-2000 contents; PVA-g-PBA: 10 phr; CPA: 70 phr; PSA: 40 phr.

water, water molecules could only enter WSR by means of diffusion, capillarity, and surface sorption, so that both  $R_{w1}$  and  $R_{v1}$  were very slow. It took 23 days for a WSR sample with no PEG to reach maximum water absorption. In WSR, CHR is the continuous phase and CPA grains are the dispersive phase. Each water-absorbent resin grain was isolated from others by a rubber phase and could not give full play to the water-absorbing ability. When PEG was added, it built bridges among water-absorbent resin grains and supplied water-absorbing routes. With an increase in PEG content, the number of water-absorbing routes increased, and the water-absorbing rate speeded up. Figures 3 and 4 also show that although  $R_{w1}$ and  $R_{v1}$  with smaller PEG content were slower,

**Figure 5** Relationship of  $L_{w1}$  to PEG-2000 contents; PVA-*g*-PBA: 10 phr; CPA: 70 phr; PSA: 40 phr.

**Figure 6** Relationship of  $S_{w2}$  to soak time with various PEG-2000 contents; PVA-g-PBA: 10 phr; CPA: 70 phr; PSA: 40 phr.

 $S_{w1m}$  and  $S_{v1m}$  of the samples with smaller PEG content obtained from a longer time period were almost equal to those with a larger PEG content. This can be explained by the slower water-absorbing rate because of fewer routes, but maximum values could finally be achieved through a longer term as long as routes existed.

 $L_{w1}$ . Figure 5 shows that with an increase in PEG content,  $L_{w1}$  increased rapidly.  $L_{w1}$  with no PEG was about 5%, while  $L_{w1}$  with 50-phr PEG was 23%. Because of this, PEG dissolved easily in water so that PEG was taken out by water in the course of water swelling.

**Figure 7** Relationship of  $S_{v2}$  to soak time with various PEG-2000 contents; PVA-g-PBA: 10 phr; CPA: 70 phr; PSA: 40 phr.

**Figure 8** Relationship of  $S_w$  to soak time at various PEG-2000 contents; PVA-*g*-PBA: 10 phr; CPA: 70 phr; PSA: 40 phr.

# Effect of PEG on the Second Water-Swelling Abilities

Figures 6 and 7 show that the effect of PEG on the second water-absorbing and water-swelling abilities was similar to that on the first water-swelling abilities. With an increase in PEG content, the impact of the water-absorbing accelerant also increased, so that both  $R_{w2}$  and  $R_{v2}$  speeded up. However,  $R_{w2}$  and  $R_{v2}$  were less than  $R_{w1}$  and  $R_{v1}$ . Except for the sample with 15 phr PEG, the addition of 25 phr, 40 phr, and 50 phr PEG made  $S_{w2m}$  and  $S_{v2m}$  of the samples equal to or higher than  $S_{w1m}$  and  $S_{v1m}$ , respectively. Compared

**Figure 9** Relationship of  $S_v$  to soak time at various PEG-2000 contents; PVA-g-PBA: 10 phr; CPA: 70 phr; PSA: 40 phr.

**Figure 10** Relationship of  $S_{w1}$  to soak time at various PSA contents; PVA-g-PBA: 10 phr; CPA: 70 phr; PEG-2000: 40 phr.

with  $S_{v1m}$  with 50 phr PEG,  $S_{v2m}$  increased by more than 10%. This may be explained by the fixing of the route volume occupied by PEG molecules when the mixed compound was cured during preparation of WSR. After PEG was taken out by water, the routes fixed by the crosslinked networks still existed and would allow water to pass through.

# Effect of PEG on Long-Term Water-Retention Abilities

After long-term soaking in water,  $S_w$  and  $S_v$  of the sample with 40 phr PEG were almost equal to those of the sample with 50 phr PEG (Figs. 8 and 9), which indicates 40 phr PEG could meet the need of our WSR.

**Figure 11** Relationship of  $S_{v1}$  to soak time at various PSA contents; PVA-*g*-PBA: 10 phr; CPA: 70 phr; PEG-2000: 40 phr.

# **Effect of PSA**

#### Effect of PSA on the First Water-Swelling Abilities

 $R_{w1}$ ,  $R_{v1}$ , and  $S_{w1m}$ ,  $S_{v1m}$ . Figures 10 and 11 show that  $S_{w1m}$  and  $S_{v1m}$  decreased with increasing PSA content. It is probable that when PSA content was modest, the chloromethyl side group of CHR reacted with the hydroxyl groups of PSA during vulcanization to form ether bonds and made the crosslinked networks of WSR smaller (Fig. 12), this is similar to G. J. Wang's work.<sup>5</sup> With an increase in PSA content, the size of the crosslinked networks decreased, which set a limit to the expansion of WSR and absorption of water. However, with an increase in PSA content,  $R_{w1}$ and  $R_{v1}$  sped up. Presumably this is because the free PSA that didn't form ether bonds interacted with water to form hydrogen bonds, so that PSA could absorb water upon its surface and speed up  $R_{w1}$  and  $R_{v1}$ . When PSA content was equal to or higher than 40 phr,  $R_{w1}$  and  $R_{v1}$  tended to be constant.

**Figure 13** Relationship of  $L_{w1}$  to PSA contents; PVAg-PBA: 10 phr; CPA: 70 phr; PEG-2000: 40 phr.

 $L_{w1}$ . With an increase in PSA content,  $L_{w1}$  increased (Fig. 13). When PSA content was high enough to consume almost all chloromethyl groups, the free PSA whose hydroxyl groups reacted with no chloromethyl groups might be taken out easily by water. The higher the PSA content, the more the free PSA was taken out.

# Effect of PSA on the Second Water-Swelling Abilities

Figures 14 and 15 illustrate that the effect of PSA on the second water-absorbing and water-swelling abilities was different from that on the first ones. With an increase in PSA content,  $R_{w2}$  and  $R_{v2}$  slowed down because loss of free PSA, PEG, and CPA in higher PSA content samples was more than those in lower ones in the course of the first water absorbing and the first water swelling. In addition,  $S_{w2m}$  and  $S_{v2m}$  decreased with in-

**Figure 14** Relationship of  $S_{w2}$  to soak time at various PSA contents; PVA-*g*-PBA: 10 phr; CPA: 70 phr; PEG-2000: 40 phr.

**Figure 15** Relationship of  $S_{w2}$  to soak time at various PSA contents; PVA-*g*-PBA: 10 phr; CPA: 70 phr; PEG-2000: 40 phr.

creasing PSA content, just as those in the first water-absorbing and -swelling test did. Except for the sample with 20 phr PSA, the second waterabsorbing and water-swelling abilities were poorer than the first ones; this may be due to the loss of free PSA, CPA, and PEG. That the second maximum water-absorbing ratio of the sample with 20 phr PSA was more than the first one may be attributed to the proper size of crosslinked networks and the lower loss of free PSA, PEG, and CPA.

# Effect of PSA on Long Term Water Retention Abilities

After long-term soaking in water, the  $S_w$  and  $S_v$  of the sample with 80 phr PSA were less than

**Figure 16** Relationship of  $S_w$  to soak time at various PSA contents; PVA-*g*-PBA: 10 phr; CPA: 70 phr; PEG-2000: 40 phr.

**Figure 17** Relationship of  $S_v$  to soak time at various PSA contents; PVA-g-PBA: 10 phr; CPA: 70 phr; PEG-2000: 40 phr.

those of the sample with 40 phr PSA (Figs. 16 and 17) because the size of crosslinked networks of the former was smaller than those of the latter.

# **CONCLUSIONS**

- 1. The WAXD patterns show that in the binary blend of PEG and CHR or the ternary blend of PEG, CHR, and CPA, PEG dispersed homogeneously and could not agglomerate by itself to form a crystalline region.
- 2. With PEG content increasing,  $R_{w1}$ ,  $R_{v1}$ ,  $R_{w2}$ , and  $R_{v2}$  sped up and  $L_{w1}$  increased, but evidently  $S_{w1m}$  and  $S_{v1m}$  did not increase. For the sample with the same PEG content,  $R_{w2}$  and  $R_{v2}$  were less than  $R_{w1}$  and  $R_{v1}$ . But compared with  $S_{v1m}$  with 50 phr PEG,  $S_{v2m}$  increased by more than 10%.
- 3.  $R_{w1}$  and  $R_{v1}$  sped up, but  $R_{w2}$  and  $R_{v2}$  decreased when PSA content increased.

Table IEffect of Amount of PEG on MaximumWater-Swelling Properties

	15 phr	$25 \mathrm{~phr}$	40 phr	50 phr
$S_{w^{1m}}$	5.03	4.68	4.74	5.46
$S_{v1m} \ S_{w2m}$	$6.57 \\ 2.87$	$6.36 \\ 4.85$	$\begin{array}{c} 6.61 \\ 4.03 \end{array}$	$7.41 \\ 5.16$
$S_{v2m}$	3.48	7.17	6.56	8.17

	20 phr	40 phr	60 phr	80 phr
$S_{w1m}$	7.42	5.45	5.45	4.07
$S_{v1m}$	10.14	7.51	7.2	6.03
$S_{w2m}$	8.05	4.67	4.59	2.72
$S_{v2m}$	9.45	6.69	4.99	3.82

Table IIEffect of Amount of PSA on MaximumWater-Swelling Properties

Moreover,  $S_{w1m}$ ,  $S_{v1m}$ ,  $S_{w2m}$ , and  $S_{v2m}$ decreased with an increase in PSA content. For the sample with the same PSA content,  $R_{w2}$  and  $R_{v2}$  were less than  $R_{w1}$  and  $R_{v1}$ . However,  $S_{w2m}$  with 20 phr PSA was more than  $S_{w1m}$ .

4. Various component contents have an influence on  $R_{w1}$ ,  $R_{v1}$ ,  $S_{w1m}$ ,  $S_{v1m}$ ,  $L_{w1}$ ,  $R_{w2}$ ,  $R_{v2}$ ,  $S_{w2m}$ ,  $S_{v2m}$ ,  $R_{w2}$ ,  $S_w$ , and  $S_v$ . As far as water-absorbing and -swelling abilities are concerned, the optimums within the range of the experiment were: CHR, 100 phr; CPA, 70 ~ 100 phr; compatibilizer PVA-g-PBA, 5 ~ 10 phr; PEG, 40 ~ 50 phr; and PSA, 40 ~ 60 phr. The first maximum water-swelling ratio by volume was 11.95, and the second maximum water-absorbing ratio by weight was 9.31.

The authors are indebted to The National Natural Science Foundation of China and the Doctoral Foundation of The National Education Committee of China for the financial support of this project.
