#### Abstract

We obtain sufficient conditions on a real valued function $f$, continuous on $[0,+\infty)$, to insure that, for some nonnegative integer $n$, there is a nonnegative number $r(n)$ so that for any $r \geqslant r(n)$, the polynomial of best approximation to $f$ on $[0, r]$ from $\pi_{n}$ is increasing and nonnegative on $\left[r,+\infty\right.$ ). Here, $\pi_{n}$ denotes the set of all real polynomials of degree $n$ or less. The proofs of Theorems 1 and 2 use only properties of Lagrange interpolation while that of Theorem 3 employs results on the location of interpolation points in Chebyshev approximation.

## 1. Introduction

In this paper, we obtain sufficient conditions on a real-valued function $f$, continuous on $[0,+\infty$ ), to insure that, for some nonnegative integer $n$, there is a nonnegative number $r(n)$ so that for any $r \geqslant r(n)$, the polynomial of best approximation to $f$ on $[0, r]$ from $\pi_{n}$ is increasing and nonnegative on $\left[r,+\infty\right.$ ). (Here, $\pi_{n}$ denotes the set of all real polynomials of degree $n$ or less.)

The interest in this problem stems from a method of proof used in the study of rational Chebyshev approximation to reciprocals of entire functions as in [2], [3], and [4]. In fact, the proof of Theorem 5 in [3] uses the special

[^0]case, Corollary 1, of our Theorem 1. Namely, $f$ is assumed there to be an entire function all of whose Maclaurin coefficients are nonnegative.

However, we also feel that this is an interesting problem in its own right.
The proofs of Theorems 1 and 2 use only properties of Lagrange interpolation while Theorem 3 uses results of Rowland [5] and [6] on the location of the interpolation points in Chebyshev approximation.

## 2. Construction and Main Results

We begin by stating two lemmas whose proofs are elementary. The proof of Lemma 1 follows easily from a finite Taylor series representation for $f$ with remainder.

Lemma 1. Assume $f \in C^{m}[0,+\infty), m \geqslant 0$, satisfies $f^{(m)}(x) \geqslant B_{m}>0$ for all $x \geqslant 0$. Then, for each integer $j$ with $0 \leqslant j \leqslant m$, the quantity $r_{j}(f) \equiv$ $\inf \left\{t \geqslant 0: f^{(j)}(x)>0\right.$ on $\left.(t,+\infty)\right\}$ is finite.

The proof of Lemma 2 below follows easily from expanding the interpolating polynomial in Newton interpolation form, and using known properties of divided differences.

Lemma 2. Assume $f \in C^{m}[0,+\infty), m \geqslant 0$. Then, the following are equivalent:
(i) $f^{(m)}(x) \geqslant B_{m}>0$ for all $x \geqslant 0$;
(ii) any polynomial $p_{m} \in \pi_{m}$ which interpolates $f$ in any $m+1$ finite points (counting multiplicities) of $[0,+\infty)$ satisfies $p_{m}^{(m)}(x) \geqslant B_{m}>0$ for all $x$.

We remark that if $p_{m}$ interpolates $f \in C^{m}[0,+\infty)$ in a finite point $x_{0} \geqslant 0$ with multiplicity $k, 1 \leqslant k \leqslant m+1$, then, as is customary, this means that $\left(f-p_{m}\right)^{(i)}\left(x_{0}\right)=0$ for all $0 \leqslant i \leqslant k-1$.

Next, given $f \in C^{m}[0,+\infty)$ with $f^{(m)}(x) \geqslant B_{m}>0$ for all $x \in[0,+\infty)$, let the finite numbers $r_{j}(f), 0 \leqslant j \leqslant m$, be defined as in Lemma 1 , and define the nonnegative quantity $C_{m}$ by

$$
\begin{equation*}
C_{m} \equiv-\min _{0 \leqslant j \leqslant m}\left[\min _{x \geqslant 0} f^{(j)}(x) ; 0\right] \geqslant 0 . \tag{1}
\end{equation*}
$$

Note that if all $r_{j}(f), 0 \leqslant j \leqslant m$, are zero, so is $C_{m}$. We then consider the particular polynomials $H_{j, m} \in \pi_{j}$, defined for $0 \leqslant j \leqslant m$ by

$$
\begin{equation*}
H_{j, m}(x) \equiv \frac{B_{m} x^{j}}{m!}-C_{m} \sum_{i=0}^{j-1} \frac{x^{i}}{(m-j+i)!}, \quad j>0 ; \quad H_{0, m}(x) \equiv \frac{B_{m}}{m!} . \tag{2}
\end{equation*}
$$

Lemma 3. There exists a least nonnegative real number $\sigma_{j, m}$ such that $H_{j, m}^{(i)}(x)>0$ for all $x \in\left(\sigma_{j, m},+\infty\right)$ and all $0 \leqslant i \leqslant j$. Moreover, $\sigma_{j, m}=$ $\max _{0 \leqslant i \leqslant j} \sigma_{i, m}$, and

$$
\sigma_{i, m} \leqslant\left\{\begin{array}{c}
\max \left(m-1 ; j m C_{m} / B_{m}\right) ; C_{m}>0 \\
0
\end{array}\right\} .
$$

Proof. Of course, we can choose $\sigma_{j, m}=0$ if $C_{m}=0$. In particular, we set $\sigma_{0, m}=0$. Fixing $j>0$, if $C_{m}>0$, then by Descartes' rule of signs, $H_{j, m}(x)$ has exactly one positive zero, which we define as $\sigma_{j, m}$. A classical result of Cauchy (cf. [1, p. 95]) states that all zeros $\lambda$ of $H_{j, m}$ satisfy $|\lambda| \leqslant \sigma_{j, m}$. But, if the zeros $\lambda$ of $H_{j, m}$ all lie in the disk $\left\{z:|z| \leqslant \sigma_{j, m}\right\}$, so does their convex hull. Consequently, by the Gauss-Lucas Theorem (cf. [1, p. 14]), all the zeros $\mu$ of any $H_{j, m}^{(i)}, i \geqslant 0$, also satisfy $|\mu| \leqslant \sigma_{j, m}$. Thus, $H_{j, m}^{(i)}(x)$ is of one sign on $\left(\sigma_{j, m},+\infty\right)$ and hence positive there for each $0 \leqslant i \leqslant j$.

To obtain the upper bound for $\sigma_{j, m}$ when $C_{m}>0$, first note that

$$
\frac{x^{j-1}}{(m-1)!} \geqslant \frac{x^{j-i}}{(m-i)!} \quad \text { for } \quad 1 \leqslant i \leqslant j
$$

is valid for any $x \geqslant m-1$. Thus, on adding the above inequalities,

$$
\frac{j x^{j-1}}{(m-1)!} \geqslant \sum_{i=0}^{j-1} \frac{x^{i}}{(m-j+i)!}
$$

Hence, $H_{j, m}(x) \geqslant\left(B_{m} x^{j} / m!\right)-j C_{m} x^{j-1} /(m-1)!=\left(x^{j-1} / m!\right)\left[B_{m} x-j m C_{m}\right]$ for any $x \geqslant m-1$ and $C_{m}>0$. Since the term in brackets is nonnegative for $x \geqslant j m C_{m} / B_{m}$, then $H_{j, m}(x) \geqslant 0$ for all $x \geqslant \max \left\{m-1,\left(j m C_{m} / B_{m}\right)\right\}$. But as $H_{j, m}(x) \geqslant 0$ for $x \geqslant 0$ only if $x \geqslant \sigma_{j, m}$, then

$$
\sigma_{j, m} \leqslant\left\{\begin{array}{c}
\max \left(m-1 ; j m C_{m} / B_{m}\right) ; C_{m}>0 \\
0 \quad ; C_{m}=0
\end{array}\right\} .
$$

Finally, it follows from (2) that

$$
H_{j, m}(x)=x H_{j-1, m}(x)-C_{m} /(m-j)!
$$

Since $H_{j-1, m}\left(\sigma_{j-1, m}\right)=0$, then $H_{j, m}\left(\sigma_{j-1, m}\right)=-C_{m} /(m-j)!\leqslant 0$, whence $\sigma_{j-1, m} \leqslant \sigma_{j, m}$. Thus, $\sigma_{j, m}=\max _{0 \leqslant i \leqslant j} \sigma_{i, m}$.
Q.E.D.

This brings us to
Theorem 1. Assume $f \in C^{m}[0,+\infty), m \geqslant 0$, satisfies $f^{(m)}(x) \geqslant B_{m}>0$ for all $x \geqslant 0$, and set $r(m)=r_{m}{ }^{*}+\sigma_{m, m}$, where $r_{m}{ }^{*} \equiv \max _{0 \leqslant j \leqslant m}\left(r_{j}(f)\right)$, the quantities $r_{j}(f)$ and $\sigma_{m, m}$ being defined respectively in Lemmas 1 and 3.

Then, for any $r \geqslant r(m)$, any polynomial $p_{m} \in \pi_{m}$ which interpolates $f$ in $m+1$ points (counting multiplicities) of $[0, r]$ satisfies

$$
\begin{equation*}
p_{m}^{(i)}(x)>0 \quad \text { for all } \quad x>r, \quad \text { all } \quad 0 \leqslant i \leqslant m \tag{3}
\end{equation*}
$$

Moreover, the quantity $r(m)$ can be bounded above by

$$
r(m) \leqslant r_{m}^{*}+\left\{\begin{array}{c}
\max \left(m-1 ; m^{2} C_{m} / B_{m}\right) ; C_{m}>0  \tag{4}\\
0 \quad ; C_{m}=0
\end{array}\right\} .
$$

Before proving Theorem 1, several comments can be made. First, for any $r \geqslant 0$, if $p_{m}$ interpolates $f$ in $m+1$ points of [0,r], it follows from Lemma 2 that $p_{m}^{(m)} \geqslant B_{m}>0$. Thus, applying Lemma 1 to $p_{m}$ gives us the existence of the least nonnegative real numbers $r_{j}\left(p_{m}\right) \geqslant 0$ such that $p_{m}^{(j)}(x)>0$ on $\left(r_{j}\left(p_{m}\right),+\infty\right)$ for each $0 \leqslant j \leqslant m$. Hence, $p_{m}^{(i)}(x)>0$ on $\left(R_{m},+\infty\right)$ for all $0 \leqslant i \leqslant m$, where $R_{m} \equiv \max _{0 \leqslant j \leqslant m} r_{j}\left(p_{m}\right)$, but it is in general possible that $R_{m}>r$. If $R_{m}>r$, then the desired strictly increasing nature (3) of the interpolant $p_{m}$ takes place not immediately to the right of the interpolation interval $[0, r]$, but on $\left(R_{m},+\infty\right)$. Thus, the major point in Theorem 1 is that it is possible to select $r \geqslant 0$ sufficiently large such that $R_{m} \leqslant r$, regardless of the interpolation points in $[0, r]$. Another point of Theorem 1 is that an upper bound for $r(m)$ is given in (4).

Proof. For $r \geqslant r(m)$, consider any $p_{m} \in \pi_{m}$ which interpolates $f$ in any $m+1$ points (counting multiplicities) in [0,r], and label these interpolation points

$$
0 \leqslant x_{m} \leqslant x_{m-1} \leqslant \cdots \leqslant x_{1} \leqslant x_{0} \leqslant r .
$$

Using the convention throughout that $\prod_{i=0}^{k}\left(x-x_{i}\right)=1$, whenever $k<0$, we first express $p_{m}$ in Newton interpolation series form, i.e.,

$$
\begin{equation*}
p_{m}(x)=\sum_{j=0}^{m} a_{j} \prod_{i=0}^{j-1}\left(x-x_{i}\right) \quad \text { with } \quad a_{j} \equiv f\left[x_{0}, x_{1}, \ldots, x_{j}\right] \tag{5}
\end{equation*}
$$

where $f\left[x_{0}, x_{1}, \ldots, x_{j}\right], j>1$, is the divided difference of $f$ in the points $x_{0}, x_{1}, \ldots, x_{j}$, and $f\left[x_{0}\right] \equiv f\left(x_{0}\right)$. For any $1 \leqslant j \leqslant m$, it is well-known that $f\left[x_{0}, x_{1}, \ldots, x_{j}\right]=f^{(j)}\left(\xi_{j}\right) / j$ !, where $x_{j}<\xi_{j}<x_{0}$ if $x_{j}<x_{0}$, and $\xi_{j}=x_{0}$ if $x_{j}=x_{0}$. Next, for each $i$ with $0 \leqslant i \leqslant m$, we analyze the $i+1$ "right-most" terms of $p_{m}$, by defining

$$
\begin{equation*}
p_{i, m}(x)=a_{m} \prod_{j=1}^{i}\left(x-x_{m-j}\right)+a_{m-1} \prod_{j=2}^{i}\left(x-x_{m-j}\right)+\cdots+a_{m-i} \tag{6}
\end{equation*}
$$

so that $p_{i, m} \in \pi_{i}$ for each $0 \leqslant i \leqslant m$, and also $p_{m, m}(x) \equiv p_{m}(x)$ (cf. (5)). In addition, it follows from (6) that, for $m>0$,

$$
\begin{equation*}
p_{i, m}(x)=p_{i-1, m}(x) \cdot\left(x-x_{m-i}\right)+a_{m-i}, \quad 1 \leqslant i \leqslant m \tag{7}
\end{equation*}
$$

so that (6) and (7) in essence represent a Horner-like method for recursively defining $p_{m}(x)$.

By hypothesis, $p_{0, m}(x)=a_{m}=f\left[x_{0}, x_{1}, \ldots, x_{m}\right] \geqslant f^{(m)}\left(\xi_{m}\right) / m!\geqslant B_{m} / m!$. Thus, from the definition in (2), then

$$
\begin{equation*}
p_{0, m}(x) \geqslant H_{0, m}(x)=B_{m} / m!>0 \quad \text { for all } \quad x>r . \tag{8}
\end{equation*}
$$

Next, for $m>0$, consider $p_{1, m}(x)=p_{0, m}(x) \cdot\left(x-x_{m-1}\right)+a_{m-1}$, where $a_{m-1}=f\left[x_{0}, x_{1}, \ldots, x_{m-1}\right]=f^{(m-1)}\left(\xi_{m-1}\right) /(m-1)!$, with $x_{m-1} \leqslant \xi_{m-1} \leqslant x_{0}$. Two cases arise.

Case 1. $r_{m}{ }^{*} \leqslant x_{m-1}$.
In this case, it follows from the definition of $r_{m}{ }^{*}$ in the statement of Theorem 1 that $a_{m-1} \geqslant 0$. Thus, using (8), we deduce that $p_{1, m}(x) \geqslant$ $p_{0, m}(x) \cdot\left(x-x_{m-1}\right)>0$ for all $x>r$, and that $p_{1, m}^{(1)}(x)=p_{0, m}(x)>0$ for all $x>r$, i.e.,

$$
p_{1, m}^{(i)}(x)>0 \quad \text { for all } \quad x>r \text { and for all } 0 \leqslant i \leqslant 1
$$

Case 2. $x_{m-1}<r_{m}{ }^{*}$.
In this case, for $x>r$, then $x-x_{m-1}>r-r_{m}{ }^{*} \geqslant \sigma_{m, m}$. Next, if $\xi_{m-1} \geqslant r_{m-1}(f)$, then $a_{m-1} \geqslant 0$ and we can surely bound $a_{m-1}$ below by $a_{m-1} \geqslant-C_{m} /(m-1)$ !. If $\xi_{m-1}<r_{m-1}(f)$, the previous inequality still holds from the definition of $C_{m}$. Thus, from (8),

$$
\begin{aligned}
p_{1, m}(x) & =p_{0, m}(x) \cdot\left(x-x_{m-1}\right)+a_{m-1} \geqslant\left(B_{m} \sigma_{m, m}\right) / m!+a_{m-1} \\
& \geqslant\left(B_{m} \sigma_{m, m}\right) / m!-C_{m} /(m-1)!\equiv H_{1, m}\left(\sigma_{m, m}\right)>0
\end{aligned}
$$

the last inequality following from the fact that $\sigma_{1, m} \leqslant \sigma_{m, m}$ (cf. Lemma 3), and the definition of $\sigma_{1, m}$. Upon differentiating, we further see, as in the previous case, that

$$
p_{1, m}^{(i)}(x)>0 \quad \text { for all } x>r \quad \text { and } \quad 0 \leqslant i \leqslant 1 .
$$

The inductive step is now clear. Assuming for $m>0$ that

$$
\begin{equation*}
p_{j-1, m}^{(i)}(x)>0 \quad \text { for all } \quad x>r \text { and all } 0 \leqslant i \leqslant j-1 \tag{9}
\end{equation*}
$$

and that

$$
\begin{equation*}
p_{j-1, m}(x) \geqslant H_{j-1, m}\left(\sigma_{m, m}\right) \quad \text { for all } \quad x>r \quad \text { if } \quad x_{m-(j-1)}<r_{m}^{*} \tag{10}
\end{equation*}
$$

we then consider $p_{j, m}(x)=p_{j-1, m}(x) \cdot\left(x-x_{m-j}\right)+a_{m-j}$. Recalling that $a_{m-j}=f\left[x_{0}, x_{1}, \ldots, x_{m-j}\right]=f^{(m-j)}\left(\xi_{m-j}\right) /(m-j)!$, two cases similarly arise.

Case 1. $r_{m}^{*} \leqslant x_{m-j}$.
In this case, it again follows from the definition of $r_{m} *$ that $a_{m-j} \geqslant 0$. Hence, $p_{j, m}(x) \geqslant p_{j-1, m}(x) \cdot\left(x-x_{m-j}\right)>0$ for all $x>r$ from $i=0$ of (9). Moreover, since in general

$$
\begin{equation*}
p_{j, m}^{(i)}(x)=p_{j-1, m}^{(i)}(x) \cdot\left(x-x_{m-j}\right)+i p_{j-1, m}^{(i-1)}(x) \quad \text { for any } \quad i \geqslant 1, \tag{11}
\end{equation*}
$$

it follows from the inductive hypothesis of (9) that

$$
p_{j, m}^{(i)}(x)>0 \quad \text { for all } \quad x>r \quad \text { and all } \quad 0 \leqslant i \leqslant j
$$

Case 2. $x_{m-j}<r_{m}{ }^{*}$.
In this case, for $x>r$ then $x-x_{m-j}>r-r_{m}^{*} \geqslant \sigma_{m, m}$. With the inductive hypothesis of (10), then for $x>r$,

$$
\begin{aligned}
p_{j, m}(x) & =p_{j-1, m}(x) \cdot\left(x-x_{m-j}\right)+a_{m-j} \\
& \geqslant H_{j-1, m}\left(\sigma_{m, m}\right) \cdot \sigma_{m, m}-C_{m} /(m-j)!
\end{aligned}
$$

but, as this last sum of two terms is, from (2), just $H_{j, m}\left(\sigma_{m, m}\right)$, then

$$
p_{j, m}(x) \geqslant H_{j, m}\left(\sigma_{m, m}\right)>0 \quad \text { for all } \quad x>r \quad \text { if } \quad x_{m-j}<r_{m}^{*} .
$$

Again, using (11) and the inductive hypothesis of (9), we see that

$$
p_{j, m}^{(i)}(x)>0 \quad \text { for all } \quad x>r \quad \text { and all } \quad 0 \leqslant i \leqslant j
$$

This completes the induction. Thus, since $p_{m}(x) \equiv p_{m, m}(x)$, then

$$
p_{m}^{(i)}(x)>0 \quad \text { for all } \quad x>r \text { and all } 0 \leqslant i \leqslant m . \quad \text { Q.E.D. }
$$

Of course, if $f \in C^{m}[0,+\infty)$ satisfies the hypothesis of Theorem 1 and moreover has $f^{(j)}(0) \geqslant 0$ for all $0 \leqslant j \leqslant m$, then $r(m)$ can be chosen to be zero in Theorem 1. This gives us the following.

Corollary 1. Assume $f \in C^{m}[0,+\infty), m \geqslant 0$, that $f^{(m)}(x) \geqslant B_{m}>0$ for all $x \geqslant 0$, and that $f^{(j)}(0) \geqslant 0$ for all $0 \leqslant j \leqslant m$. Then, for any $r \geqslant 0$, any polynomial $p_{m} \in \pi_{m}$ which interpolates $f$ in any $m+1$ points (counting multiplicities) of $[0, r]$ satisfies (3).

Next, given $f \in C^{\infty}[0,+\infty)$, suppose that there exists a strictly increasing sequence $\left\{n_{k}\right\}_{k=0}^{\infty}$ of nonnegative integers such that
for each nonnegative integer $k$, there exists a real number $B_{n_{k}}>0$ such that $f^{\left(n_{k}\right)}(x) \geqslant B_{n_{k}}>0$ for all $x \geqslant 0$.

Clearly, we can apply Theorem 1 to $f$ for each $m=n_{k}$, and thus, we deduce that, for each $k \geqslant 0$, there is a real number $r\left(n_{k}\right)$ such that for any $r \geqslant r\left(n_{k}\right)$, any polynomial $p_{n_{k}} \in \pi_{n_{k}}$ which interpolates $f$ in any $n_{k}+1$ points in $[0, r]$, satisfies

$$
\begin{equation*}
p_{n_{k}}^{(i)}(x)>0 \quad \text { for all } x>r \text { and all } 0 \leqslant i \leqslant n_{k} . \tag{13}
\end{equation*}
$$

Actually, what we are interested in is the manner in which the numbers $r\left(n_{k}\right)$ increase with $k$. Of course, Theorem 1 directly provides an upper bound for each $r\left(n_{k}\right)$, but, as we now show, the existence of lower derivatives strictly positive on $[0, \infty)$ allows us to sharpen the upper bound (4) of Theorem 1 for $r\left(n_{k}\right)$. Specifically, in analogy with (1) and (2), we introduce the notation

$$
\begin{array}{rlr}
C_{n_{s}} \equiv-\min _{n_{s-1}+1 \leqslant j \leqslant n_{s}}\left[\min _{x \geqslant 0} f^{(i)}(x) ; 0\right] \geqslant 0, & s=0,1, \ldots, \\
L_{s} \equiv n_{s}-\left(n_{s-1}+1\right) \geqslant 0, & s=0,1, \ldots, \tag{15}
\end{array}
$$

and, for $0 \leqslant j \leqslant L_{s}$,

$$
\begin{align*}
& H_{j, n_{s}}(x) \equiv \frac{B_{n_{s}} x^{j}}{\left(n_{s}\right)!}-C_{n_{s}} \sum_{i=0}^{j-1} \frac{x^{i}}{\left(n_{s}-j+i\right)!}, \quad j>0 ;  \tag{16}\\
& H_{0, n_{s}}(x) \equiv \frac{B_{n_{s}}}{\left(n_{s}\right)!}
\end{align*}
$$

where we set $n_{-1} \equiv-1$.
We then have the following.
Theorem 2. Let $f$ be a real-valued function in $C^{\infty}[0,+\infty)$, and let $\left\{n_{k}\right\}_{h=0}^{\infty}$ be a strictly increasing sequence of nonnegative integers for which (12) is valid. Then, for each nonnegative integer $k$, there is a real number $r\left(n_{k}\right)$ such that for any $r \geqslant r\left(n_{k}\right)$, any polynomial $p_{n_{k}} \in \pi_{n_{k}}$ which interpolates $f$ in any $n_{k}+1$ points (counting multiplicities) of $[0, r]$ satisfies

$$
p_{n_{k}}^{(i)}(x)>0 \quad \text { for all } \quad x>r \text { and all } 0 \leqslant i \leqslant n_{k} .
$$

Moreover, with $r_{n_{k}}^{*} \equiv \max _{0 \leqslant j \leqslant n_{k}}\left(r_{j}(f)\right)$, the quantities $r_{j}(f)$ being defined in Lemma 1, then

$$
\left.r\left(n_{k}\right) \leqslant r_{n_{k}}^{*}+\max _{0 \leqslant s \leqslant k} \begin{array}{c}
\left(\begin{array}{c}
n_{s} \max \left(1 ; L_{s} C_{n_{s}} / B_{n_{s}}\right) \\
0
\end{array} ; C_{n_{s}}>0\right.  \tag{17}\\
; C_{n_{s}}=0
\end{array}\right\} .
$$

Proof. As previously mentioned, the existence of such an $r\left(n_{k}\right)$ is guaranteed by Theorem 1. It remains then to establish the upper bound for $r\left(n_{k}\right)$ in (17).

For any $r \geqslant r\left(n_{k}\right)$, consider any $p_{n_{k}} \in \pi_{n_{k}}$ which interpolates $f$ in any $n_{k}+1$ points (counting multiplicities) of $[0, r]$. As in the proof of Theorem 1, label these points

$$
0 \leqslant x_{n_{k}} \leqslant x_{n_{k}-1} \leqslant \cdots \leqslant x_{0} \leqslant r
$$

Expressing $p_{n_{k}}$ in Newton interpolation series form,

$$
p_{n_{k}}(x)=\sum_{j=0}^{n_{i}} a_{j} \prod_{i=0}^{j-1}\left(x-x_{i}\right) \quad \text { with } \quad a_{j} \equiv f\left[x_{0}, x_{1}, \ldots, x_{j}\right]
$$

we then write $p_{n_{k}}$ in the form

$$
p_{n_{k}}(x)=\sum_{s=0}^{k} Q_{s}(x), \quad \text { where } \quad Q_{s}(x) \equiv \sum_{j=n_{s-1}+1}^{n_{s}} a_{j} \prod_{i=0}^{j-1}\left(x-x_{i}\right)
$$

and where $n_{-1} \equiv-1$. Note that $Q_{s} \in \pi_{n_{s}}$. Then, writing $Q_{s}$ as
$Q_{s}(x)=\prod_{j=0}^{n_{s} 1}\left(x-x_{j}\right) \cdot R_{s}(x), \quad$ where $\quad R_{s}(x) \equiv \sum_{j=n_{s-1}+1}^{n_{s}} a_{j} \prod_{i=n_{s-1}+1}^{j-1}\left(x-x_{i}\right)$,
we note that $\left(\prod_{j=0}^{n_{s-1}}\left(x-x_{j}\right)\right)^{(i)}>0$ on $(r,+\infty)$ for all $0 \leqslant i \leqslant n_{s-1}+1$. Next, with the definition of $L_{s}$ in (15), it follows that $R_{s} \in \pi_{L_{s}}$, and hence, it suffices to show that $R_{s}^{(i)}(x)>0$ for all $x \in(r, \infty)$ and for all $0 \leqslant i \leqslant L_{s}$, for, using the chain rule for differentiation of a product, this will imply that the product $Q_{s}$, as given in (18), then satisfies $Q_{s}^{(i)}(x)>0$ for all $x>r$ and all $0 \leqslant i \leqslant n_{s}$.

To show that $R_{s}^{(i)}(x)>0$ for all $x>r$ and for all $0 \leqslant i \leqslant L_{s}$, we now simply modify the proof of Theorem 1. Let $\sigma_{j, n_{s}}$, as guaranteed by Lemma 3, be the least nonnegative real number such that $H_{j, n_{s}}^{(i)}(x)>0$ for all $x>\sigma_{j, n_{s}}$ and for all $0 \leqslant i \leqslant j$, where $H_{j, n_{s}}$ is defined in (16). The proof of Lemma 3 easily shows that

$$
\sigma_{j, n_{s}} \leqslant\left\{\begin{array}{cl}
n_{s} \max \left(1 ; j C_{n_{s}} / B_{n_{s}}\right) ; & C_{n_{s}}>0 \\
0 & ; C_{n_{s}}=0
\end{array}\right\}
$$

and that $\sigma_{j, n_{s}}=\max _{0 \leqslant i \leqslant j} \sigma_{i, n_{s}}$. Thus,

$$
\sigma_{L_{s}, n_{s}}=\max _{0 \leqslant i \leqslant L_{s}} \sigma_{i, n_{s}} \leqslant\left\{\begin{array}{c}
n_{s} \max \left(1 ; L_{s} C_{n_{s}} / B_{n_{s}}\right) ; C_{n_{s}}>0  \tag{19}\\
0
\end{array} C_{n_{s}}=0\right\}
$$

Then, directly applying the inductive proof of Theorem 1 to $R_{s}$, rather than to $p_{n_{s}}$, shows that we can set $r\left(n_{k}\right)=r_{n_{k}}^{*}+\max _{0 \leqslant s \leqslant k}\left(\sigma_{L_{s}}, n_{s}\right)$, and the desired result of (17) then follows from (19).
Q.E.D.

## 3. Chebyshev Approximation

As mentioned earlier, if $f$ satisfies the assumptions of Theorem 1 , then the polynomial $p_{m}{ }^{*} \in \pi_{m}$ of best Chebyshev approximation to $f$ on $[0, r]$ from $\pi_{m}$ surely satisfies the conclusion (3) of Theorem 1 , since $p_{m} *$ interpolates $f$ in at least $m+1$ distinct points of $[0, r]$. In contrast with Theorem 1 which only uses interpolation by polynomials, the next result makes specific use of polynomials of best approximation.

Theorem 3. Assume $f \in C^{m+1}[0,+\infty), m \geqslant 0$, is such that $f^{(m+1)}(x)$ is positive and strictly increasing on $(0,+\infty)$, and set

$$
\begin{equation*}
\tilde{r}(m)=2 r_{m}^{*} /\left\{1-\cos \left(\frac{\pi}{2 m+2}\right)\right\}, \tag{20}
\end{equation*}
$$

where $r_{n} * \equiv \max _{0 \leqslant j \leqslant m}\left(r_{j}(f)\right)$, the quantities $r_{j}(f)$ being defined in Lemma 1 . Then, for any $r \geqslant \tilde{r}(m)$, the polynomial $p_{m}{ }^{*} \in \pi_{m}$ of best approximation to $f$ on $[0, r]$ from $\pi_{m}$ satisfies

$$
\begin{equation*}
p_{m}^{*(i)}(x)>0 \quad \text { for all } \quad x>r \quad \text { and all } \quad 0 \leqslant i \leqslant m . \tag{21}
\end{equation*}
$$

Proof. Let $p_{m}{ }^{*} \in \pi_{m}$ be the polynomial of best Chebyshev approximation to $f$ on $[0, r]$ from $\pi_{m}$. Now, $p_{m}{ }^{*}$ interpolates $f$ in at least $m+1$ distinct points of $[0, r]$. But, the hypothesis that $f^{(m+1)}(x)>0$ on $(0, \infty)$ gives, from Rowland [5, Corollary 2.3 and Theorem 2.2], that $p_{m}{ }^{*}$ interpolates $f$ in precisely $m+1$ distinct points of $[0, r]$. We label these points $\left\{x_{j}(r)\right\}_{k=0}^{m}$ where

$$
0<x_{0}(r)<x_{1}(r)<\cdots<x_{n}(r) \leqslant r .
$$

Next, with the result of Rowland [6, Theorem 3.3], it directly follows, because $f^{(m+1)}(x)$ is by hypothesis positive and strictly increasing on $(0, r)$, that

$$
w_{k}(r) \equiv \frac{r}{2}\left\{1+\cos \left(\frac{\left(m+\frac{1}{2}-k\right) \pi}{m+1}\right)\right\}<x_{k}(r) \quad \text { for all } \quad 0 \leqslant k \leqslant m
$$

In particular, the case $k=0$ above gives

$$
w_{0}(r)=\frac{r}{2}\left\{1-\cos \left(\frac{\pi}{2 m+2}\right)\right\}<x_{k}(r) \quad \text { for all } \quad 0 \leqslant k \leqslant m
$$

With $r_{m}^{*} \equiv \max _{0 \leqslant j \leqslant m}\left(r_{j}(f)\right)$, then $w_{0}(r) \geqslant r_{m} *$ is equivalent to $r \geqslant$ $2 r_{m}^{*} /\{1-\cos (\pi /(2 m+2))\} \equiv \tilde{r}(m)$ from (20). Hence, for any $r \geqslant \tilde{r}(m)$,

$$
\begin{equation*}
r_{m}^{*} \leqslant w_{0}(r)<x_{k}(r) \quad \text { for all } \quad 0 \leqslant k \leqslant m \tag{22}
\end{equation*}
$$

Now, if we express, as before, $p_{m} *$ in Newton interpolation series form, i.e.,

$$
\begin{equation*}
p_{m}^{*}(x)=\sum_{j=0}^{m} a_{j} \prod_{i=0}^{j-1}\left(x-x_{i}(r)\right) \quad \text { with } \quad a_{j} \overline{\Xi=} f\left[x_{0}(r), \ldots, x_{j}(r)\right] \tag{23}
\end{equation*}
$$

then $a_{j}=f^{(j)}\left(\xi_{j}\right) / j$ ! with $x_{0}(r)<\xi_{j}<x_{j}(r)$ for all $1 \leqslant j \leqslant m$, and $a_{0}=f\left(x_{0}(r)\right)$. Hence, for any $r \geqslant \tilde{r}(m)$, it follows from (22) and the definition of $r_{m}{ }^{*}$ that $a_{j}>0$ for all $0 \leqslant j \leqslant m$. Thus, differentiating the expression for $p_{m}^{*}$ in (23) then yields

$$
p_{m}^{*(i)}(x)>0 \quad \text { for all } \quad x>r \quad \text { and all } \quad 0 \leqslant i \leqslant m . \quad \text { Q.E.D. }
$$

## 4. Examples and Remarks

As in the transition from Theorem 1 to Theorem 2, we can apply Theorem 3 to the case where $f \in C^{\infty}[0,+\infty)$, and where $\left\{n_{k}\right\}_{k=0}^{\infty}$ is a strictly increasing sequence of nonnegative integers for which $f^{\left(n_{k}+1\right)}(x)$ is positive and strictly increasing on $(0,+\infty)$ for each $k=0,1, \ldots$. If we further assume that $f$ is such that $\sup _{j \geqslant 0}\left(r_{j}(f)\right) \leqslant R<\infty$, it follows from Theorem 3 that, for each $k \geqslant 0$, the polynomial $p_{n_{k}}^{*} \in \pi_{n_{k}}$ of best approximation to $f$ on $[0, r]$ from $\pi_{n_{k}}$ satisfies

$$
p_{n_{k}}^{*(i)}(x)>0 \quad \text { for all } x>r \text { and all } 0 \leqslant i \leqslant n_{k}
$$

where $r \geqslant 2 R /\left\{1-\cos \left(\pi /\left(2 n_{k}+2\right)\right)\right\} \geqslant \tilde{r}\left(n_{k}\right)$. In this situation, these upper bounds for $\tilde{r}\left(n_{k}\right)$ are $\mathcal{O}\left(n_{k}{ }^{2}\right)$ as $k \rightarrow \infty$.

Similarly, if $f \in C^{\infty}[0,+\infty)$ is such that $\sup _{j \geqslant 0}\left(r_{j}(f)\right) \leqslant R<\infty$, and if $\sup _{k \geqslant 0}\left(L_{k} C_{n_{k}} / B_{n_{k}}\right) \leqslant D<\infty, D \geqslant 1$, then it follows from Theorem 2 that, for each $k \geqslant 0$, any polynomial $p_{n_{k}} \in \pi_{n_{k}}$ which interpolates $f$ in any $n_{k}+1$ points (counting multiplicities) of $[0, r]$ satisfies

$$
p_{n_{k}}^{(i)}(x)>0 \quad \text { for all } \quad x>r \quad \text { and all } \quad 0 \leqslant i \leqslant n_{k}
$$

where $r \geqslant R+D n_{k} \geqslant r\left(n_{k}\right)$. Thus, in this case, these upper bounds for $r\left(n_{k}\right)$ are $\mathcal{O}\left(n_{k}\right)$ as $k \rightarrow \infty$.

We now apply the above remarks to the specific function

$$
f(x)=e^{x}+e^{\alpha} \cos x, \quad \alpha<\ln (\sqrt{2})+(3 \pi / 4) \doteqdot 2.703
$$

On differentiating $f$, one sees that Theorem 2 is applicable for the sequence $n_{0}=0, n_{1}=3, n_{2}=4, n_{3}=7, n_{4}=8$, etc. On the other hand, Theorem 3 will apply with the sequence $n_{0}=2, n_{1}=6, n_{2}=10$, etc. Thus, Theorem 2 and 3 are independent and interlace here.
