#### Abstract

Summary New pulse sequences are introduced and discussed that allow for simultaneous acquisition of ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}-\mathrm{HSQC}$ correlations for fully ${ }^{13} \mathrm{C},{ }^{15} \mathrm{~N}$-labeled biomacromolecules in combination with heteronuclear gradient echoes and sensitivity enhancement. The pulse sequence experimentally found to be optimal can be used as a building block, especially in time-consuming malitidimensional NMR experiments. Due to the excellent solvent suppression obtained by employing heteronuclear gradicnt echoes, which allows detection of resonances under the water resonance, it would be possible to record two sensitivity-enhanced 4 D experiments simultaneously on one sample dissolved in $\mathrm{H}_{2} \mathrm{O}$, e.g. a $4 \mathrm{D}{ }^{13} \mathrm{C}_{2}^{1} \mathrm{H}$ -HSQC-NOESY- ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{HI} /{ }^{3} \mathrm{C},{ }^{1} \mathrm{H}-\mathrm{HSQC}$.

In NMR spectroscopy of biomacromolecules it is desirable to record all experiments on a single sample dissolved in $\mathrm{H}_{2} \mathrm{O}$, in order to reduce the number of samples and at the same time increase the comparability of spectra. This is cven more essential for costly isotopically labeled samples. For such samples excellent suppression of water and artifacts, e.g. $t_{1}$ noise, can be achieved in heteronuclear experiments (Hurd and John, 1991) that make use of heteronuclear gradient echoes (Maudsley et al., 1978).

Implementations of heteromuclear corrclation experiments with and without application of a heteronuclear gradient echo differ in the type of coherence selected during the evolution time (Schleteher et al, 1993). While the Cartesian operators of the type $\mathrm{I}_{x}, \mathrm{I}_{y}$ that lead to an amplitude-modulated signal are selected in alternating transients in conventional cxperiments without the application of gradients, the application of a gradient echo necessarily implies that the operators $\mathrm{T}^{+}$or $\mathrm{I}^{-}$are selected, yielding a phase-modulated signal. Whether $\mathrm{I}^{+}$or $\mathrm{I}^{-}$is selected depends on the relative amplitude of the gradients causing the heteronuclear gradient echo. Echo and antiecho data yield spectra with pure phases by appropri-
ate processing (Palmer et al., 1991). However, the pulse sequences that transfer Cartesian operators (amplitudemodulating pulse sequences) yield reduced sensitivity when heteronuclear gradient echoes are incorporated. By contrast, when pulse sequences are used that transfer spin operators of the type $\mathrm{I}^{+}$or $\mathrm{I}^{-}$to $\mathrm{I}^{-}$, and thus yield a coherence order-selective transfer, no loss in sensitivity occurs upon formation of a heteronuclear gradient echo (Kay et al., 1992; Schleucher et al., 1993). Therefore, sequences that transfer Coherence Orders in a Selective (COS-coherence transfer) way (Palmer et al., 1991; Kay et al., 1992; Muhandiram et al., 1993; Schleucher et al., 1993,1994; Muhandiram and Kay, 1994) are highly desirable because introduction of gradients does not lead to a loss in signal-to-noise. In the first implementation of this principle (Palmer et al., 1991; Kay et al., 1992; Schleucher et al., 1993) (Fig. 1a), $\mathrm{X} \rightarrow \mathrm{H}$ transfer is achicved by a COS-INEPT step. In this experiment, sensitivity enhancement of a factor $\sqrt{2}$ can be achieved for the transfer of antiphase heteronuclear coherence $2 F_{z} S^{-}$to $F^{-}\left(F^{-}=\sum_{i}^{n} I_{i}\right)$ in IS spin systems, compared to conventional pulse sequences. Roughly equal sensitivity can be obtained for $I_{2} S$ and $I_{3} S$ spin systems (Schleucher et al., 1994).

Fig. I. (a) Sensitivity-enhanced ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}-\mathrm{HSQC}$ and ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}$-HSQC with COS-INEPT for the $\mathrm{X} \rightarrow \mathrm{H}$ transfer. $\Delta=1 / 2 \mathrm{~J}_{\mathrm{NH}}$ and $\Delta^{\prime}=1 / 2 \mathrm{~J}_{\mathrm{CA}}$. The first gradient is a homospoil gradient, the second $\left(\mu \mathrm{G}_{\mathrm{z}}\right)$ effects coherence order selection. Note the different phases $\psi=-\mathrm{y}$ and $\xi=\mathrm{y}$, due to the different sign of the gyromagnetic ratios of ${ }^{15} \mathrm{~N}$ and ${ }^{13} \mathrm{C}$. All pulse phases are x , unless indicated otherwise. Composite pulscs ( $90^{\circ}{ }^{\circ}$, $180^{\circ}, 90^{\circ}$ ) are used for the inversion of $z$-magnetization of the ${ }^{3} \mathrm{C}$ and ${ }^{15} \mathrm{~N}$ spins. (b-d) Three different possible implementations of simultaneous sensitivity-enhanced ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}-$ and ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}-\mathrm{HSQC}$ with $\mathrm{COS}-\mathrm{CT}$. In all sequences longitudinal two-spin order $2 \mathrm{~F}_{\mathrm{z}} \mathrm{S}_{\mathrm{z}}$ ( $\mathrm{F}^{-}=\sum_{i}^{\mathrm{K}} \mathrm{I}_{\mathrm{a}}^{-}$) for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ is stored at the beginning of the evolution time (point a) to allow for the longer $t_{1}$ increment of nitrogen, $(1+\kappa) \Delta t_{1}$, compared to that of carbon ( $\left.\Delta t_{1}\right)$. The gradients applied lead to equal dephasing of carbon and nitrogen coherence after the evolution time, as explained in the text. (b) The initial part of the COS-INEPT (box with dashed line) for the ${ }^{1} \mathrm{H}-{ }^{15} \mathrm{~N}$ s systems is identical to the sequence in Fig. 1a. The first threc carbon pulses (solid box) of the COS-INEPT for the ${ }^{1} \mathrm{H}^{13} \mathrm{C}$ systems are positioned centrosymmetrically in the middle of the equivalent pulses for the ${ }^{1} I I^{15} \mathrm{~N}$ systems. The two $180^{\circ}\left({ }^{13} \mathrm{C}\right)$ pulses at positions $d$ and e scrve to refocus the ${ }^{6} \mathrm{~J}_{\mathrm{CII}}$ couplings during $\tau / 2$. (c) Compared to the sequence in (b), the refocussing of ${ }^{1} \mathrm{~J}_{\mathrm{CH}}$ during $\tau / 2$ is now achieved by two pairs of $180^{\circ}\left({ }^{1} \mathrm{H}^{15} \mathrm{~N}\right)$ pulses at positions $d$ ande. The sequence in Fig. 1 b suffers from the ewolution of ${ }^{1} \mathrm{~J}_{13}{ }^{13}{ }^{13} \mathrm{c}$ couplings for $t_{1}$ $=0$ and the large number of pulses that have to be applied compared to the reference experiments in (a). (d) This sequence is recommended. It avoids the evolution of C,C coupling to a large extent by positioning the first three carbon pulses of the ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}-\mathrm{COS}$-INEPT (solid box) at the begianing of the first pulses of the ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}-\mathrm{COS}$-INEPT. Compared to (a), only one pair of $180^{\circ}\left({ }^{1} \mathrm{H},{ }^{15} \mathrm{~N}\right.$ ) pulses has to be applied additionally. This sequence and the sequence of (b) were used to record the simultaneous ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}-$ and ${ }^{1} \mathrm{C},{ }^{1} \mathrm{H}-\mathrm{HSQC}$ shown in Fig. 2. (e) Reduction of the COSINEPT parts of the sequence in (d) to either of the sequences in (a). For the ${ }^{35} \mathrm{~N} \rightarrow{ }^{1} \mathrm{HI}$ transfer, the $180^{\circ}\left({ }^{1} \mathrm{H},{ }^{15} \mathrm{~N}\right.$ ) pulse pair can be shifted to the left. The first $180^{\circ}\left(^{15} \mathrm{~N}\right)$ pulse commutes with the first $90^{\circ}\left({ }^{15} \mathrm{~N}\right)$ pulse. The $180^{\circ}\left({ }^{\prime} \mathrm{H}\right)$ pulse is merged with the first $90^{\circ}\left({ }^{1} \mathrm{H}\right)$ pulse, yielding a $90^{\circ} \varepsilon^{\prime}\left({ }^{1} \mathrm{H}\right)$ pulse. Since the sign of this pulse phase is irrelevant for the coherence selected, the reduced sequence on the right can be regarded as identical with the sequence in (a). For the ${ }^{13} \mathrm{C} \rightarrow{ }^{1} \mathrm{H}$ transfer (lower part sequences), the delay $\Delta-\Delta / 2$ (crossed out) can be omitted since no heteronuclear coupling evolves. The hatched $180^{\circ}\left(\frac{H}{\prime}\right)$ pulse can be shifted to the left through the delay $\Delta / 2$, requiring a sign change in one or the gradients or a $180^{\circ}$ phase change in, for example, the second $90^{\circ}\left({ }^{(3} \mathrm{C}\right)$ pulse. Since the sign of the phase of the first $90^{\circ}\left({ }^{3} \mathrm{H}\right)$ pulse is irrelevant, the sequence on the right can be regarded as identical to the one in (a).

Fig. 1. (continued).

In addition, sensitivity obtained for a given experiment time can be enhanced by simultaneous acquisition of e.g. ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}$-correlations in heteronuclear correlation experiments which contain as a final step an HSQC-like transfer from heteronuclear coherence to proton coherence (Sørensen, 1990; Farmer, 1991; Boelens et al., 1994; Mariani et al., 1994). The application of simultaneous experiments is highly desirable for the most time-consuming experiments, i.e., 4D HSQC-NOESYHSQC (Ikura et al., 1990; Clore et al., 1991; Zuiderweg et al., 1991) and has been shown to be feasible for a 3D NOESY-HSQC experiment (Pascal et al., 1994). Simultaneous ${ }^{13} \mathrm{C} \rightarrow{ }^{1} \mathrm{H}$ and ${ }^{15} \mathrm{~N} \rightarrow{ }^{1} \mathrm{H}$ correlation has also been used in a simultaneous $\mathrm{H}(\mathrm{X}) \mathrm{YH}$ correlation experiment (Mariani, 1994). Simultaneous ${ }^{15} \mathrm{~N}^{-1} \mathrm{H}$ and ${ }^{13} \mathrm{C}^{-1} \mathrm{H}$ excitation has been used for 4D HSQC-NOESY-HSQC by Farmer and Mueller (1994).

In this communication, we introduce a building block that allows sensitivity-enhanced simultaneous ${ }^{13} \mathrm{C}-{ }^{-} \mathrm{H}$ and ${ }^{15} \mathrm{~N}-{ }^{1} \mathrm{H}$ detection and is compatible with the use of a heteronuclear gradient echo for water suppression. The rationales behind the design of the pulse sequence are the following. First, the pulse sequence should meet the requirement that the chemical shift region of the carbons must have a smaller $t_{1}$ increment than that of nitrogen. Second, the different size of the heteronuclear coupling constants ${ }^{1} \mathbf{J}_{\mathrm{N}, \mathrm{H}}$ and ${ }^{1} \mathrm{~J}_{\mathrm{C}, \mathrm{H}}$ should also be taken into account during defocussing and refocussing. And third, all proton magnetization should pass the final $\mathrm{B}_{0}$-gradient applied to protons before detection. Therefore, transverse nitrogen magnetization must be subjected to a 2.5 times stronger gradient than transverse carbon magnetization. This requires application of gradients during delays in the sequence where nitrogen and carbon magnelization have different coherence orders. Three pulse sequences that meet these requirements and have been experimentally tested are shown in Figs. 1b-d and are discussed in the following.

Due to the smaller spectral width of nitrogen compared to carbon, the chemical shift evolution of nitrogen with an increment of $(1+\kappa) \Delta t_{1}$ starts earlier in all sequences (point a) than that of carbon (point b) with an increment $\Delta t_{1}$ in the sequences of Figs. $1 \mathrm{~b}-\mathrm{d}$. Carbon magnetization is stored as $2 \mathrm{~F}_{z} \mathrm{~S}_{\pi}$ (where F refers to the proton and $S$ to the carbon spin) between points a and $b$ in all pulse sequences (Figs. lb-d), while nitrogen magnetization is transverse already. In Figs. 1 b and $\mathrm{d}, \mathrm{B}_{0}-$ gradients $\mu \mathrm{G}_{z}(\mu=\mp 6)$ are applied during that time and the nitrogen magnetization is dephased with $\mp 6 \mathrm{G}_{7} \gamma_{\mathrm{N}}$. In the pulse sequence of Fig. le the gradients of amplitude $2 \mu_{1} G_{z}\left(\mu_{1}=\mp 4\right)$ and $\mu_{2} G_{z}\left(\mu_{2}=\mp 2\right)$ already yield dephasing of the transverse nitrogen magnetization by $\left(2 \mu_{1}-\mu_{2}\right) \mathrm{G}_{\mathrm{z}} \gamma_{\mathrm{N}}=\mp 10 \mathrm{G}_{\mathrm{z}} \gamma_{\mathrm{N}}$. (Note that a $180^{\circ}$ pulse inverts the coherence order of magnetization, so that gradients applied before and after a $180^{\circ}$ pulse must have
different signs to be additive.) Then the carbon magnetization is also turned into the transverse plane (point $b$ in Figs. 1b-d) and a gradient $\lambda \mathrm{G}_{2}(\lambda= \pm 4)$ in the sequences of Figs. 1 b and d and two gradients $\lambda_{2} \mathrm{G}_{2}\left(\lambda_{2}=\overline{+}\right)$ in the sequence of Fig. Ic are applied that dephase transverse carbon magnctization by $\pm 4 \mathrm{G}_{\mathrm{z}} \gamma_{c}$. In the sequences of Figs. 1 b and d , the gradient $\lambda \mathrm{G}_{\bar{z}}$ also yields a dephasing of the transverse nitrogen magnetization by $\mp 4 \mathrm{G}_{z} \gamma_{\mathrm{N}}$, which adds to the phase $\mp 6 \mathrm{G}_{z} \gamma_{N}$, acquired between points $a$ and $b$. By contrast, in the sequence of Fig. 1c no dephasing of nitrogen magnetization is effected by the two gradients $\lambda_{2} \mathrm{G}_{\mathrm{x}}$, due to the refocussing $180^{\circ}\left({ }^{15} \mathrm{~N}\right)$ pulse at point d. At this point, nitrogen ( $\mp 10 \mathrm{G}_{\mathrm{z}} \gamma_{\mathrm{N}}$ ) and carbon ( $\pm 4 \mathrm{G}_{z} \gamma_{C}$ ) have acquired identical dephasing in the sequences of Figs. $1 b-d$, due to the $B_{0}$-gradients, since $\gamma_{13 \mathrm{c}} / \gamma_{15_{\mathrm{N}}}=-2.5$. Note that the coherence orders of nitrogen and carbon magnetization are different in sign because of the negative sign of the ratio of $\gamma_{13 \mathrm{C}} / \gamma_{15_{\mathrm{N}^{*}}}$. The $180^{\circ}$ pulses on either proton, carbon or nitrogen between points $a$ and $c$ ensure that neither ${ }^{1} J_{C, H}$ nor ${ }^{1} J_{\mathrm{N}, \mathrm{H}}$ couplings evolve during $t_{1}$ and that chemical shifts for carbon and nitrogen are refocussed for $t_{1}=0$.

The most important differences between the three sequences (Figs. 1b-d) are found for the ${ }^{15} \mathrm{~N} \rightarrow{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C} \rightarrow{ }^{1} \mathrm{H}$ COS-INEPT. Since the proton pulses affeet the protons bound to carbon as well as those bound to nitrogen, they must be used for both proton species. In the first (Fig, 1b) and second implementation (Fig. lc), the $\mathrm{N} \rightarrow \mathrm{H}$ transfer is essentially unchanged compared to Fig. la, except for additional $180^{\circ}(\mathrm{II}, \mathrm{N})$ pulses in the dotted box. (Fig. lc) which, however, do not change the evolution of any interaction compared to the ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}-\mathrm{HSQC}$ employing COS-INEPT (Fig. la, upper half). For sequences in Figs. 1 b and c the carbon pulses in the solid box are placed symmetrically in the middle of the nitrogen pulses in the dotted box. Carbon and proton/nitrogen $\pi$ pulses, respectively, are placed in the sequences of Figs. 1 b and c in such a way that the ${ }^{1} \mathrm{~J}_{\mathrm{H}, \mathrm{N}}$ coupling evolves during $1 / 2^{1} \mathrm{~J}_{\mathrm{H}, \mathrm{N}}$ and the ${ }^{1} \mathrm{~J}_{\mathrm{H}, \mathrm{C}}$ coupling during $1 / 4^{1} \mathrm{~J}_{\mathrm{H}, \mathrm{C}}$. The disadvantage of the implementation in Fig. lb is the prolonged time during which the ${ }^{1} \mathrm{~J}_{13 \mathrm{C},{ }^{13} \mathrm{C}}$ couplings evolve compared to the reference experiment in Fig. 1a, namely $t / 2=1.8 \mathrm{~ms}$. In addition, more pulses have to be applied on either ${ }^{13} \mathrm{C}$ (Fig. Ib) or ${ }^{1} \mathrm{H}$ and ${ }^{15} \mathrm{~N}$ (Fig. 1c). The implementation in Fig. 1d, which puts the first three carbon pulses (solid box) asymmetrically at the beginning of the first delay $\Delta=1 / 2^{1} \mathrm{~J}_{\mathrm{H}, \mathrm{N}}$, solves both problems. No transverse carbon magnetization is left after the $90^{c}\left(^{13} \mathrm{C}\right)$ pulse with phase $\xi$. For $t_{1}=0$ the ${ }^{1} J_{13 \mathrm{C}, 13 \mathrm{C}}$ couplings evolve during $2 \tau_{\mathrm{G}}$ and also during $\Delta^{\prime / 2}$ for one of the Cartesian magnetization components, which is identical to the reference experiment. Only one additional pair of $180^{\circ}$ $\left({ }^{1} \mathrm{H}_{2}^{15} \mathrm{~N}\right.$ ) pulses is needed for the simultaneous COSINEPT of Fig. Id compared to the COS-INEPT parts of the reference experiments (Fig. 1a).

Fig. 2. Simultaneous sensitivity-enhanced ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}$ - HSQC of a 2 mM sample of completely ${ }^{13} \mathrm{C}$ - and ${ }^{[5} \mathrm{N}$-labeled rhodniin, a 103 -residuc protein, in a Sbigemi tube. K was set to 1.77 and the $\mathrm{t}_{1}$ increment $\Delta \mathrm{t}_{1}$ to $200 \mu \mathrm{~s}$, yielding spectral widths of 1805 Hz for ${ }^{15} \mathrm{~N}$ and 5000 Hz for ${ }^{13} \mathrm{C}$, resulting in folding of the aliphatic carbons. The figure shows correlations between ${ }^{15} \mathrm{~N}, \mathrm{H}$ and aliphatic ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}$. Note the excellent water suppression that allows observation of the $\mathrm{H}^{\alpha}$ resonances even under the water resonance.

Some remarks should be made regarding the signs of the pulse phases $(\psi, \xi)$ and gradients in the different sequences. The COS-INEPT part (after the evolution time) of the pulse sequences in Fig. la accomplishes an effective Hamiltonian for an IS spin system: $2 \pi \mathrm{~J}\left(\mathrm{~T}_{\mathrm{x}} \mathrm{S}_{\mathrm{x}}+\right.$ $\mathrm{I}_{y} \mathrm{~S}_{\mathrm{y}}$ ) with $\psi=-90^{\circ}$. This Hamiltonian leads to an antiecho transfer. Inverting the sign of either of the two $90^{\circ}(\mathrm{S})$ pulses or of either of the second or third $90^{\circ}(\mathrm{I})$ pulses, the effective Hamiltonian is: $2 \pi J\left(I_{x} S_{x}-1_{y} S_{y}\right)(\psi=$
$90^{\circ}$, which leads to an echo transfer and therefore requires opposite gradient signs compared to the antiecho transfer. Taking the sequences in Fig. 1at as a reference, rules are provided that allow reduction of any of the sequences in Figs. 1b-d to those in Fig. 1a. If we ignore the chemical shift evolution that is refocussed by the $180^{\circ}$ pulses, then (i) a pair of $180^{\circ}(\mathrm{I}, \mathrm{S})$ pulses can be shifted until a $90^{\circ}$ pulse is reached, because the heteronuclear coupling Hamiltonian $2 \pi \mathrm{II}_{z} \mathrm{~S}_{2}$ commutes with the

Fig. 3. Representative traces through the simultaneous ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}-\mathrm{HSQC}$ recorded in 1.5 h with the optimized pulse sequence of Fig. 1d (bothom) and with the less sensitive pulse sequence of Fig. 1b (top). The middle trace was obtaimed from a ${ }^{13} \mathrm{C}$, ${ }^{1} \mathrm{H}-\mathrm{IISQC}$ with a COS-INEPT tratsfer (Fig. la, lower half) with $\Delta^{\prime}=1 / 2 T_{\mathrm{CH}}$ (for lig. 3a) and from a ${ }^{15} \mathrm{~N}, \mathrm{~T} 1-\mathrm{HSQC}$ with a COS-INEPT transfer (Fig. la, upper hall) with $\Delta=$ $1 / 2 \mathrm{~J}_{\mathrm{NH}}$ (for Fig. 3b), each recorded in 0.75 h . The pulse sequence of Fig. 1 b achieves the maximum enhancement of $\sqrt{2}$ ( $1.41 \pm 0.09$ ) for ${ }^{15} \mathrm{~N}, \mathrm{I} \mathrm{H}$ spin systems (upper trace in b), but only $0.79 \pm 0.16$ for ${ }^{13} \mathrm{C}^{1} \mathrm{H}$ spin systems (upper trace in a) due to the large number of ${ }^{3} \mathrm{C}$ pulses and the evo-
 of Fig. la (middle traces), we find that a slight enhancenent of $1.07 \pm 0.14$ (lower trace in a) is obtained for ${ }^{13} \mathrm{C}{ }^{\prime} \mathrm{H}$ correlations, while almost full enhancement of $1.34 \pm 0.1$ is obtained for the ${ }^{\text {" }} \mathrm{N},{ }^{\prime} \mathrm{H}$ correlation (lower trace in b).
propagator of such a pulse pair: $\left[\exp \left(i \pi I_{\mathrm{s}}\right) \exp \left(i \pi S_{\mathrm{x}}\right)\right.$, $\left.2 \pi I_{z} S_{z}\right]=0$; (ii) two delays of equal duration ( $\beta / 2 \pi J_{I S}$ ), symmetrically about either a $180^{\circ}(\mathrm{I})$ or $180^{\circ}(\mathrm{S})$ pulse, can be omitted since hetcronuclear coupling is refocussed by a single $\pi$ pulse; and (iii) one $180^{\circ}$ pulse can be moved from one side to the other side of a delay $\left(\beta / 2 \pi I_{\text {IS }}\right)$ during which heteronuclear coupling evolves. At the same time, the direction of evolution of the heteronuclear coupling is inverted due to the following identity: $\exp \left(i \pi I_{v}\right) \exp (i \beta$ $\left.I_{z} S_{z}\right)=\exp \left(-i \beta I_{z} S_{z}\right) \exp \left(i \pi I_{x}\right)$. This can be compensated by phase inversion of, for example, the second $90^{\circ}(\mathrm{S})$ pulse.

These rules therefore provide a tool to determine the appropriate combinations of gradient signs and pulse phases for the COS-INEPT transfer. Figure le explains this point, using the ${ }^{15} \mathrm{~N} \rightarrow \mathrm{H}$ and ${ }^{13} \mathrm{C} \rightarrow \mathrm{H}$ transfer in the sequence of Fig. 1d as an example.

To compare the performance of the pulse sequences, 2D simultaneous ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}-$ and ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}-\mathrm{HSQC}$ experiments with COS-INEPT were recorded on a 2 mM sample of the ${ }^{13} \mathrm{C}$, ${ }^{15} \mathrm{~N}$-labeled protein rhodniin with the pulse sequences of Figs. $1 b-d$ (measuring time 1.5 h ). These experiments are compared with two separately recorded ${ }^{13} \mathrm{C}_{3}{ }^{1} \mathrm{H}-\mathrm{HSQC}$ and ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}-\mathrm{HSQC}$ experiments with $\mathrm{COS}-$ INEPT (pulse sequences of Fig. 1a) that each ran for 0.75 h. An increase in sensitivity of $\sqrt{2}$ for all signals represents the upper limit for the enhancement. The 2D correlation obtained with the pulse sequence of Fig. 1d is shown in Fig. 2. Note the excellent water suppression that allows obscrvation of the $\mathrm{H}^{\alpha}$ resonances under the water resonance. If the $1 \mathrm{D}^{1} \mathrm{H}$ spectra of the ${ }^{15} \mathrm{~N}$ - and ${ }^{13} \mathrm{C}$-bound protons overlap, the ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}$ correlation spectra can be separated by appropriate phase cyeling of the ${ }^{15} \mathrm{~N}$ and ${ }^{13} \mathrm{C}$ phases (Sørensen, 1990; Farmer, 1991).

Traces through the spectra recorded with the sequences of Figs. $1 b$ and $d$ are compared to the corresponding reference experiments (Fig. 1a) in Fig. 3. From analysis of $24 \mathrm{~N}, \mathrm{H}$ and $66 \mathrm{C}, \mathrm{H}$ resolved peaks, we conclude that the experiment of Fig. $1 b$ achieves the theoretical sensitivity enhancement of $\sqrt{2}$ for $\mathrm{N}, \mathrm{H}$ spin systems $(1.41 \pm 0.09)$, but yields only $0.79 \pm 0.16$ for $\mathrm{C}, \mathrm{H}$ spin systems. This is probably due to the large number of ${ }^{13} \mathrm{C}$ pulses and the evolution of $\mathrm{C}, \mathrm{C}$ coupling, as explained above. For the experiment of Fig. 10, which contains more ${ }^{1} \mathrm{H}$ and ${ }^{15} \mathrm{~N}$ pulses than the sequence in Fig. 1a, the sensitivity of the simultaneous experiment is decreased for both N,H (0.96 $\pm 0.08)$ and $\mathrm{C}, \mathrm{H}$ spin systems $(0.93 \pm 0.09)$. The optimal implementation with respect to evolution of C, C coupling and number of pulses (Fig. 1d) achieves a sensitivity enhancement of $1.34 \pm 0.1$ for the ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}$ correlation and $1.07 \pm 0.14$ for the ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}$ correlation. Even for the optimal sequence of Fig. Id the sensitivity enhancement of the ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}$ correlation in the simultaneous experiment is reduced, due to proton and carbon relaxation during the simultancous COS-INEPT, which, by contrast to the
${ }^{19} \mathrm{C},{ }^{1} \mathrm{H}-\mathrm{COS}-\mathrm{INEPT}$, must accommodate two ${ }^{1} \mathrm{~J}_{\mathrm{N}, \mathrm{H}}$ refocussing periods and is thercfore 5 ms longer. The sensitivity of the $\mathrm{C}, \mathrm{H}$ correlation can be improved by reducing the delay $\Delta$ for evolution of the ${ }^{1} \mathrm{~J}_{\mathrm{NH}}$ coupling from 5.4 to $\sim 4 \mathrm{~ms}$, at the cost of $\sim 9 \%$ sensitivity reduction for the N,H correlation. At the same time the sensitivity of the C, H correlation increases by $15 \%$ for a ${ }^{13} \mathrm{C}_{2}$ of 20 ms .

In conclusion, we have introduced a simultaneously recorded ${ }^{15} \mathrm{~N},{ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C},{ }^{1} \mathrm{H}-\mathrm{HSQC}$ experiment with COS-INEPT transfers. In the optimal implementation atcording to the sequence in Fig. 1d, the sensitivity is increased compared to the sequential recording of the experiments and excellent solvent suppression is achieved by the formation of a heteronuclear gradient echo.
